T-cell immunoglobulin mucin-3 (Tim-3) plays roles in the functional regulation of both adaptive and innate immune cells and is greatly involved in many diseases. However, the precise roles of Tim-3 on macrophages (M\(\phi\)s) in pregnancy remain unstated. In the current study, we found the higher frequency of Tim-3\(^+\) decidual M\(\phi\)s (dM\(\phi\)s) in response to trophoblasts. The reduced abundance of Tim-3 on M\(\phi\)s was accompanied by disordered anti- and pro-inflammatory cytokine profiles in miscarriage. Adoptive transfer of Tim-3\(^+\) M\(\phi\)s, but not Tim-3\(^-\) M\(\phi\)s, relieved murine embryo absorption induced by M\(\phi\) depletion. Our flow cytometry results and the extensive microarray analysis confirmed that Tim-3\(^+\) and Tim-3\(^-\) dM\(\phi\)s were neither precisely pro-inflammatory (M1) nor anti-inflammatory (M2) M\(\phi\)s. However, with higher CD132 expression, Tim-3\(^+\) dM\(\phi\)s subset induced Th2 and Treg bias in decidual CD4\(^+\) T cells and promoted pregnancy maintenance. Blockade of Tim-3 or CD132 pathways led to the dysfunction of maternal-fetal tolerance and increased fetal loss. These findings underscored the important roles of Tim-3 in regulating dM\(\phi\) function and maintaining normal pregnancy, and suggested that Tim-3 on M\(\phi\)s is a potential biomarker for diagnosis of miscarriage. Our study also emphasized the importance of careful consideration of reproductive safety when choosing immune checkpoint blockage therapies in real world clinical care. Though IL-4 treated Tim-3\(^+\) M\(\phi\)s could rescue the fetal resorption induced by M\(\phi\) depletion, whether IL-4 represent novel therapeutic strategy to prevent pregnancy loss induced by checkpoint inhibition still needs further research.

INTRODUCTION

Either impaired tolerance induction or excessive inflammation is believed to be associated with a lot of pregnancy-related complications, such as recurrent spontaneous abortion (RSA) [1]. Substantial research in reproductive and transplant immunology has been made to address the mechanism that the avoidance of immune attack by the semi-allogeneic fetus that has fetal histocompatibility antigens inherited from the father, while at the same time protecting the mother and the fetus from pathogens during pregnancy. For many years, Treg expansion and a polarization toward Th2 bias in the maternal immune response have long been considered the main mechanisms of inducing tolerance toward the fetus [2]. Now we believed that various kinds of cells, especially those residing at the maternal-fetal interface, play critical roles in this ‘immunological paradox’ of pregnancy [3].

The maternal-fetal interface is a highly dynamic tissue where the extravillous trophoblast cells (Tros) invade the decidua and come into direct contact with the decidual cells, and the appropriate crosstalk between each other is crucial for successful pregnancy. In early pregnancy, approximately 30–40% of total decidual cells are immune cells, of which macrophages (M\(\phi\)s) are the most important specialized antigen presenting cells and the second most abundant leucocytes (10–20% of the decidual immune cells) at the maternal-fetal interface. The depletion of M\(\phi\)s after conception has been reported to cause fetal resorption and embryo implantation arrest [4, 5], highlighting the importance of M\(\phi\)s during pregnancy. Decidual M\(\phi\)s (dM\(\phi\)s) are associated with the success of pregnancy by regulating immune responses and promoting decidual vascular remodeling [6]. Environmental cues and molecular mediators polarize M\(\phi\)s as type 1 M\(\phi\)s (M1) and type 2 M\(\phi\)s (M2). M1 are more effective at antigen clearance and switching T cell responses toward Th1 immune response with the high expression of CD80, CD86, IL-12, and TNF-\(\alpha\). While M2 have more immunosuppressive capacities, contributing to tissue remodeling, and promoting Th2 immune responses with the high expression of CD163, CD206, CD209, and IL-10 [7]. Imbalance of M1/M2 leads to a pathological pregnancy, such as RSA [8].

T-cell immunoglobulin mucin-3 (Tim-3) is first identified as a specific cell surface marker of Th1 cells, and it mediates T cell exhaustion and apoptotic cell phagocytosis in chronic virus infection, organ transplantation and tumorigenesis. Later, Tim-3 was also found to be expressed on innate immune cells, such as M\(\phi\)s [9]. However, the role of Tim-3 on M\(\phi\)s is complex and
controversial depending on distinct microenvironments in contrast to its well-recognized effects on T cell immunity. For example, it was reported that Tim-3 reduced the release of pro-inflammatory cytokines, such as IFN-γ and IL-12 by Mψs in inflammatory bowel disease and ameliorated the colitis [10]. While Tim-3 was also found to aggravate podocyte injury by promoting Mψs activation in diabetic nephropathy [11]. In pregnancy, Tim-3 is strikingly upregulated on monocytes in the peripheral blood compared to nonpregnant women [12]. In addition, Tim-3 blockade resulted in a decrease in phagocytic properties of dMψs leading to a failure to clear dead and apoptotic cells from the uterus [13].

We previously reported that downregulation or blockade of Tim-3 is associated with miscarriage by regulating T cell and NK cell functions [14, 15]. However, there are no studies demonstrating in full how Mψ Tim-3 works in the maternal-fetal immunity during early pregnancy. With all this information, we chose to determine the expression of Tim-3 on dMψs and to investigate its contribution to the maternal-fetal tolerance. In the present study, we found that the expression of Tim-3 was higher on dMψs in normal pregnancies than that in miscarriages. We also used normal pregnancy mouse model, abortion-prone mouse model, Mψ depletion and adoptive transfer experiments to determine the involvement of Mψ Tim-3 in pregnancy maintenance. Our findings showed evidence supporting the critical role of Tim-3 in inducing maternal-fetal tolerance by regulating dMψ functions and by regulating the crosstalk between dMψs and decidual CD4+ T(dCD4+ T) cells.

**RESULTS**

Tros contributed to the higher proportion of Tim-3+ CD14+ cells at the maternal-fetal interface

We first compared the expression levels of Tim-3 on CD14+ cells from peripheral blood freshly isolated from non-pregnant women of childbearing age, and from paired decidua and peripheral blood from clinically normal first trimester pregnancies. Tim-3 was expressed on significantly higher proportions of peripheral monocytes (pMos) from pregnant women compared to that from nonpregnant women. While Tim-3 expression on dMψs was much higher than that on pMos during pregnancy (Fig. 1A).

Then we wanted to know why Tim-3 was highly expressed during pregnancy? The placenta has been regarded as a pseudo-malignant type of tissue due to the invasive property, high proliferation and immune escape capacity. As tumor micro-environment is responsible to the re-education of Mψs into tumor-associated Mψs [16], we established a co-culture system of Tros and pMos from non-pregnant or pregnant women. As shown in Fig. 1B, after 48 h, the frequency of Tim-3+ pMos increased, both in non-pregnant and pregnant women.

At the maternal-fetal interface, invading Tros, maternal-derived decidual stromal cells (DSCs), and decidual immune cells (DICs), come into direct contact with each other. We found that primary Tros and HTR8/Svneo cell line (an immortalized human extravillous trophoblast cell line), but not DSCs, could raise the expression of Tim-3 on dMψs. Separation of Tros and dMψs with a transwell insert eliminated the promotion of Tim-3 expression by

Expression of Tim-3 on CD14+ cells during human early pregnancy. A Flow cytometric analysis and quantification of frequency of Tim-3 expression on gated CD14+ cells from peripheral blood mononuclear cells (PBMCs) isolated from non-pregnant women of childbearing age (n = 9), and from paired PBMCs and decidual immune cells (DICs) during human first trimester pregnancy (n = 48). ***p < 0.001. B Quantification of flow cytometric analysis of Tim-3 expression on peripheral CD14+ (pCD14+) cells isolated from non-pregnant women or pregnant women, with or without co-culture with trophoblasts (Tros) for 48 h, n = 20. ***p < 0.001. C Quantification of flow cytometric analysis of Tim-3 expression on dCD14+ cells cultured alone or co-cultured with equal numbers of Tros (directly or indirectly), or decidual stromal cells (DSCs), or human HTR8/Svneo cells. The α-HLA-G/HLA-C antibodies were used in some wells. *p < 0.05, **p < 0.01, compared with the control. #p < 0.05, ##p < 0.01, compared with the group co-cultured with Tros. Data represent the mean ± standard error of the mean (SEM). The flow cytometry plots are representative of three independent experiments.
Tros. The semi-allogeneic Tros have a unique human leukocyte antigen that expressing class I HLA-C and nonclassical HLA-G antigens [17]. Interestingly, administration of anti-HLA-C antibody, but not anti-HLA-G antibody, significantly inhibited Tros-induced up-regulation of Tim-3 expression on dMφs (Fig. 1C).

Disorder of the number and function of Tim-3⁺ dMφs in miscarriage
Next, we compared the frequency of Tim-3⁺CD14⁺ cells from normal pregnancy and RSA patients. We found that the number of Tim-3⁺CD14⁺ cells was lower in RSA patients than that form normal pregnancy, both in peripheral blood mononuclear cells (PBMCs) and DICs (Fig. 2A). Apart from the decreased frequency, Tim-3⁺ dMφs in RSA patients expressed more TNF-α, but less CD206, CD80, IL-4 (Fig. 2B). We also established an abortion-prone model using female CBA/J x male DBA/2 mice, and observed similar phenomenon that decreased number and disordered function of Tim-3⁺ dMφs in miscarriage (Fig. 2C).

Blockade of Tim-3 led to dMφs dysfunction and murine fetal loss
As the frequency and function of Tim-3⁺ dMφs were both altered in miscarriage, we further tested whether blocking the Tim-3 pathway could change the functionalities of dMφs. In the first assay, expression levels of intracellular cytokines and transcription factors in human dMφs were analyzed. Compared with the control group, blockade of Tim-3 increased M1-associated CD80, CXCL9, CXCL10, IL-12/23 and TNF-α expression, but decreased M2-associated CD163 and CCL17 expression, and STAT-6 phosphorylation level in human dMφs (Fig. 3A).

In the second assay, we examined pregnant CBA/J females challenged with Tim-3 blocking antibody. Analysis of the dMφs from the treated mice revealed that CD206, IL-10, TGF-β1 expression and STAT6 phosphorylation level were decreased. While CD80, TNF-α, IL-12/23 expression and STAT-1 phosphorylation level were increased (Fig. 3B). Furthermore, treatment with Tim-3 blocking antibody caused decreased growth in body

**Fig. 2** Decreased cell number of Tim-3⁺ CD14⁺ cells with deficient function in miscarriage. 
A Frequency of Tim-3 expressing cells in gated CD14⁺ cells of paired PBMCs and DICs from normal pregnant subjects (NPH, normal pregnancy of human, n = 40) and patients who diagnosed as recurrent spontaneous abortion (RSA, n = 40) as determined by flow cytometric analysis. A representative dot plot is also shown. B Surface molecule expression and cytokine production by Tim-3⁺ decidual CD14⁺ (Tim-3⁺ dCD14⁺) cells from normal pregnancy and RSA was assessed by flow cytometric analysis. Data represent the mean ± SEM. *P < 0.05, **P < 0.01. NPH: normal pregnancy of human, RSA: recurrent spontaneous abortion. C Frequency of Tim-3 expressing cells in gated F4/80⁺ cells from DICs of normal pregnant (NP, n = 17) and abortion-prone (AP, n = 18) mice. A representative dot plot is also shown. D Quantification of flow cytometric analysis of surface molecule expression and cytokine production by Tim-3⁺ df4/80⁺ cells from NP (n = 5) and AP (n = 4) mice. Data represent the mean ± SEM. *P < 0.05, **P < 0.01, ***P < 0.001. NP: normal pregnancy, AP: abortion prone. Data are representative of 4-5 independent analyses. *P < 0.05, **P < 0.01.
weight (Fig. 3C), reduction in the number of live fetuses per uterus, and a higher rate of embryo resorption (Fig. 3D). In addition, blockade of Tim-3 also increased the Th1-associated TNF-α, IFN-γ and T-bet, but decreased Th2-associated IL-4 and GATA-3 and Treg-associated TGF-β1, IL-10 and Foxp3 expression by dCD4+ T cells (Supplementary Fig. 1). Taken together with our in vitro data, Tim-3 pathway regulated immune responses in dMφs playing important role in the maintenance of maternal-fetal tolerance so to promote the establishment of normal pregnancy.

Adoptive transfer of Tim-3+ Mφs relieved murine embryo absorption induced by Mφ depletion

To provide direct insight into the role of Tim-3+ Mφs in maternal-fetal immune regulation and pregnancy outcome in vivo, we evaluated the effect of Mφ depletion and adoptive transfer of Tim-3+ Mφs on these processes. We isolated Tim-3+ and Tim-3− Mφs from pregnant mouse spleen and transferred them to Mφ-depleted pregnant mice. We found that adoptive transfer of Tim-3+ Mφs, not Tim-3− Mφs, could significantly relieve the murine embryo absorption induced by Mφ depletion (Fig. 4A). To investigate the process of Tim-3+ Mφs differentiation in the uterus in vivo, we labeled these Tim-3+ and Tim-3− Mφs with PKH-67 and transferred them to Mφ-deleted pregnant mice (Supplementary Fig. 2).

In comparison with the PKH-67-Tim-3+ Mφs transferred group, PKH-67-Tim-3− Mφs recruited to uterus presented lower levels of CD80, CD86 and TNF-α, higher levels of Tim-3, and an increase in Th2 and Treg bias in dCD4+ T cells in Mφ-deleted pregnant mice. While dCD4+ T cells in the transfer of PKH-67-Tim-3+ Mφs group expressed lower IL-4, TGF-β1, IL-10 and GATA-3, but higher TNF-α than that of PKH-67-Tim-3− Mφs transferred group (Fig. 4C). It seemed that Tim-3+ Mφs and Tim-3− Mφs could differently regulate dCD4+ T cell function during pregnancy. To confirm this conjecture, we further co-cultured human dCD4+ T cells with Tim-3+ dMφs or Tim-3− dMφs and analyzed the expression levels of intracellular cytokines and transcription factors in dCD4+ T cells. As shown in Supplementary Fig. 3, Tim-3+ dMφs increased Th2-associated IL-4, IL-13 and GATA-3, and Treg-associated IL-10, TGF-β1 and Foxp3 expression, but decreased Th1-associated IFN-γ expression in dCD4+ T cells. While Tim-3− dMφs decreased IL-4, IL-13, GATA-3 and IL-10 expression in dCD4+ T cells. Compared with Tim-3+ dMφs, Tim-3− dMφs induced more Th2- and Treg-associated cytokines and transcription factors, but less IFN-γ expression in dCD4+ T cells. Interestingly, neither Tim-3+ dMφs nor Tim-3− dMφs had effect on TNF-α, IL-17A production and T-bet and RORγt expression by dCD4+ T cells.

**Tim-3− dMφs and Tim-3+ dMφs showed distinct CD132 expression indicative of different functional regulation on dCD4+ T cells**

We wanted to know why Tim-3− Mφs and Tim-3+ Mφs played different roles in pregnant outcomes and dCD4+ T cell function. We first compared the M1 and M2 markers of Tim-3− dMφs and Tim-3+ dMφs by flow cytometry (FCM). Unexpectedly, Tim-3− dMφs expressed higher surface molecules, cytokines and transcription factors than Tim-3+ dMφs, almost all the M1 and M2 markers (Supplementary Fig. 4A). Next, we conducted microarray profiling on highly purified populations isolated by FCM to understand what genomic differences distinguish these dMφ subsets. Unique gene signatures for Tim-3− Mφs and Tim-3+ Mφs were generated based on 1.2-fold differential expression between the two different Mφ population. These commonly differentially expressed probes from Tim-3− dMφs and Tim-3+ dMφs were highlighted on the combined data sets and presented as a volcano plot and a cluster analysis heat map.
gene expression profile. This aroused our interest as IL-4 was important for T cell tolerance while Tim-3 + dMφs were increased, while Tim-3 + dMφs were overexpressed in the Tim-3 + dMφs population as compared with the Tim-3 - dMφs. As shown in Fig. 5C, Tim-3 + dMφs promoted Th2- and Treg-associated cytokines and transcription factors expression in dCD4 + T cells. Pretreatment with anti-Tim-3 or anti-CD132 or anti-IL-4 antibody all could notably reverse the functional regulation of Tim-3 + dMφs on dCD4 + T cells. Thus Tim-3 + dMφs and Tim-3 - dMφs showed CD132 expression indicative of different functional regulation on dCD4 + T cells.

Fig. 5 Tim-3 + dMφs and Tim-3 - dMφs showed distinct CD132 expression indicative of different functional regulation on dCD4 + T cells. A The volcano plot and cluster analysis heat map of the differential mRNAs between Tim-3 + dMφs and Tim-3 - dMφs form human normal early pregnancy. Volcano plot based on fold change and p value of genes from the unique signatures of Tim-3 + dMφs and Tim-3 - dMφs in comparison with each other. Red dots mark the genes with significantly increased or decreased expression. Heatmap result of an unsupervised hierarchical clustering of genes that is significantly different in Tim-3 + dMφs samples compared with Tim-3 - dMφs samples. For example, gene encoding IL2RG was overexpressed in the Tim-3 + dMφs population as compared with the Tim-3 - dMφs. B Flow cytometric analysis and quantification of CD132 (the protein product of IL2RG gene) by human Tim-3 + dMφs and Tim-3 - dMφs (n = 9). **p < 0.01, compared with group of Tim-3 - dMφs. The flow cytometry plots are representative of three independent experiments. C Flow cytometric analysis and quantification of Th2- and Treg-related cytokine expression by human dCD4 + T cells co-cultured with Tim-3 + dMφs in the present or absence of anti-Tim-3 antibody, anti-CD132 antibody, or anti-IL-4 antibody. Data represent the mean ±SEM. *p < 0.05, **p < 0.01, compared with the control group.

We further tested whether blocking the CD132 pathway could influence the murine pregnancy outcome of Tim-3 + Mφs adoptive transfer. As shown in Fig. 6A, treatment with either anti-CD132 or anti-IL-4 antibody counteracted the protective effect of Tim-3 + Mφs adoptive transfer on Mφ deleted murine pregnancy. Compared with Tim-3 + Mφs transferred group, additional treatment with anti-CD132 or anti-IL-4 antibody caused greater susceptibility to fetal loss, leading to higher rate of embryo resorption. Does the more fetal loss of treated mice result from the dysfunction of Mφs under anti-CD132 or anti-IL-4 antibody treatment? Analysis of the Mφs from the treated mice revealed that CD80 and IL-23/23 expression of Mφs were increased, while
CD206 and IL-10 expression were decreased (Fig. 6B). In addition, blockade of CD132 pathway also influenced dCD4+ T cell tolerance as IL-4, IL-13, TGF-β1 and IL-10 production, and GATA-3 and Foxp3 expression of dCD4+ T cells were decreased. These data suggested that Tim-3+ Mφs with the capacity to induce Th2 and Treg bias in dCD4+ T cells via CD132 pathway contributed to maternal-fetal tolerance and pregnancy maintenance.

While additional treatment with IL-4 in Tim-3+ Mφs transferred group rescued the fetal resorption induced by Mφ depletion (Fig. 7A), which was concomitant with the increased M2-associated cytokines production by dMφs (Fig. 7B) and Th2- and Treg-associated cytokines production by dCD4+ T cells (Fig. 7C). Thus IL-4 could also regulate Tim-3+ Mφ function through other receptors at the same time.

**DISCUSSION**

RSA is a prevalent and distressing disorder that defined as two or more consecutive pregnancy losses prior to 20 weeks of gestation. The psychological and physical burden on the women is often unacceptable, and it can be compounded that with each loss they experience. However, progress in predicting and preventing RSA has been hampered by the uncertainties surrounding the pathogenesis. It is well recognized that either impaired tolerance induction or excessive inflammation is believed to be associated with RSA [1]. In humans, dMφs may be involved in Tros invasion, vascular remodeling, and the development of maternal-fetal tolerance [6]. In the present study, we supplied evidence that Tim-3 was a key regulator of dMφ function and therefore played important roles in the maintenance of normal pregnancy.

Increased evidence demonstrated the dynamic expression and diverse functions of Tim-3 in different disease models, especially in tumors, infections and autoimmune diseases [21–23]. Our present study demonstrated that Tim-3 expression in dMφs was significantly increased in normal pregnancy and acted as a modulator in the maintenance of normal pregnancy. This increased expression might due to local microenvironment at the maternal-fetal interface. On the basis of direct contact, embryonic Tros contributed to the increased Tim-3 expression on dMφs in an HLA-C-restricted manner. However, DSCs had no
effect on the Tim-3 expression on dMφs, further confirming the importance of Tros in the establishment of maternal-fetal tolerance that maternal immune cells could be educated by embryonic Tros to develop a unique phenotype and tolerate the fetus [24, 25]. The number and function of Tim-3+ dMφs in the decidua were significantly impaired in miscarriage, and adoptive transfer of Tim-3+ dMφs, not Tim-3- dMφs relieved murine embryo absorption induced by Mφ depletion also suggesting that the expression of Tim-3 on dMφs during pregnancy might conduce to the maintenance of maternal-fetal immune tolerance and normal pregnancy.

Tim-3 not only works as a checkpoint of T cell activation but also plays important roles in Mφ functions by regulating cell activation, cytokine release, and phagocytic property, contributing to the progress of various diseases [13, 21]. Using Tim-3-blocking antibody, we clearly showed that Tim-3 suppressed anti-inflammatory cytokines of dMφs both in vivo and in vitro. We also found that pro-inflammatory cytokines of dCD4+ T cells was elevated after the addition of anti-Tim-3 antibody. Furthermore, pregnant CBA/J females treated with Tim-3-blocking antibody became more susceptible to fetal loss, although the further development of any surviving embryos needs additional study. Blockade of Tim-3 to improve immune cell responses is considered as novel strategies for the treatment of tumors and chronic infections [26, 27]. However, with the potential of birth defects and unknown risks of harm to mothers, and use of Tim-3 blockade agents in pregnancy would likely pose great risk of abortion, reproductive safety would ultimately be an individualized decision made with careful consideration of potential benefits and risks.

Mφs have remarkable plasticity allowing them to respond efficiently to varying environmental stimuli, and dMφs have always been identified as M2 in normal pregnancy that abnormally activated dMφs can disrupt the tolerance at the maternal-fetal interface [6]. However, mounting evidence indicated that initial classification scheme was an over-simplification.

Fig. 7  IL-4 treated Tim-3- Mφs also relieved murine embryo absorption induced by Mφ depletion. A Representative images of uterus and the percent of fetal resorption in pregnant CBA/J mice with Mφ depletion that received adoptive transfer of indicated Tim-3 Mφs. B Flow cytometric analysis and quantification of frequency of surface molecule, cytokine and transcription factor expression by dF4/80− cells from pregnant CBA/J females with Mφ depletion that received adoptive transfer of indicated Tim-3 Mφs. C Quantification of flow cytometric analysis of cytokine production and transcription factor expression by dF4/80+ T cells from pregnant CBA/J females with Mφ depletion that received adoptive transfer of indicated Tim-3 Mφs. Data represent the mean ± SEM of n = 6−9 mice per group. *p < 0.05, **p < 0.01, compared with the Tim-3- Mφs group.
The protein product of suf treated with anti-Tim-3 antibody were not the same as Tim-3 innate and adaptive immune systems [20]. Tim-3 survival, and differentiation of multiple cell lineages of both the IL-4, IL-7, IL-9, IL-15, and IL-21, play crucial roles in the proliferation, cytokine expression in the whole dMφ that immune activation is required to facilitate Tros invasion and establishment of fetal-maternal tolerance. Interestingly, the cytokine expression in the whole dMφ treated with anti-Tim-3 antibody were not the same as that in Tim-3+ dMφ. Blockade of Tim-3 even increased the expression of some M1-associated markers in the whole dMφ. Anti-Tim-3 antibody might be not sufficient enough to block all the Tim-3 signal in dMφs, so dMφs treated with anti-Tim-3 antibody were not the same as Tim-3+ dMφs. Whether anti-Tim-3 antibody effects other pathways that regulating M1 and M2 differentiation still needs further study. However, these results further confirmed that Mφs have remarkable plasticity allowing them to respond efficiently to varying environmental stimuli.

Further analysis revealed that IL2RG gene were overexpressed in the Tim-3+ dMφs population as compared with the Tim-3 dMφs. The protein product of IL2RG gene is CD132, also known as the common gamma chain. CD132-dependent cytokines, including IL-2, IL-4, IL-7, IL-9, IL-15, and IL-21, play crucial roles in the proliferation, survival, and differentiation of multiple cell lineages of both the innate and adaptive immune systems [20]. Tim-3+ dMφs and Tim-3+ dMφs showed CD132 expressional differences resulting in unique function on regulating dCD4+ T cell tolerance. In addition, blockade of CD132 pathway counteracted the protective effect of Tim-3+ Mφs on maternal-fetal tolerance and murine pregnancy.

IL-4 is a CD132-dependent cytokine known to activate the Jak-STAT pathway [30], which is important for functional regulation of CD4+ T cells and Mφs. Level of IL-4 increases throughout normal pregnancy [31]. Administration of IL-4 could decrease the resorption rate in abortion prone mice [32]. Deficiency of IL-4 induced systemic and placental inflammation in mice and low IL-4 level was found in women with RSA [31]. Our present study demonstrated that additional treatment Tim-3+ Mφs with anti-IL-4 antibody caused higher rate of embryo resorption than that in the adoptive transfer group alone. Furthermore, dysfunction of dMφs and dCD4+ T cells by the production of disordered cytokines maybe associated with the fetal loss induced by additional anti-IL-4 antibody treatment. While treatment with IL-4 in Tim-3+ Mφs transferred group rescued the fetal resorption induced by Mφ depletion. As CD132 expression was much lower in Tim-3+ Mφs, IL-4 might also play regulatory role through other receptors that expressed on dMφs at the same time. In fact, previous report demonstrated that anti-inflammatory activities of IL-4 can be attributed to the direct action of this cytokine on myeloid effector cells, depending on their expression of the IL-4 receptor alpha chain CD124 [33].

Collectively, our data describe the potential role of Tim-3 on Mφs as an inducer of maternal-fetal tolerance in pregnancy (Fig. 8). We identified a distinct subset of dMφs, Tim-3+ Mφs, with immune-regulatory activity during normal pregnancy. With higher CD132 expression, Tim-3+ Mφs induced Th2 and Treg bias in dCD4+ T cells and promoted pregnancy maintenance. The reduced abundance of Tim-3 on Mφs was accompanied by disordered anti- and pro-inflammatory cytokine profiles in miscarriage. Blockade of Tim-3 or CD132 pathways led to the dysfunction of maternal-fetal tolerance and increased fetal loss. While IL-4 treated Tim-3+ Mφs, via unknown receptor, could rescue the fetal resorption induced by Mφ depletion.

Fig. 8 Schematic diagram of functional regulation of Tim-3+ Mφs on maternal-fetal tolerance. Previously we reported that Tros directly contributed to the Tim-3, PD-1 and CTLA-4 expression on dCD4+ T cells. These checkpoint pathways, in turn, may operate within the functional immune-modulatory network not only to promote maternal-fetal tolerance but also improved Tros function. The current study demonstrated that Tros also induced the higher Tim-3 expression on dMφs during normal pregnancy in HLA-C dependent manner. Neither Tim-3− nor Tim-3+ dMφs population can be categorized as strictly M1 or M2. With higher CD132 expression, Tim-3+ dMφs induced Th2 and Treg bias in dCD4+ T cells and promoted pregnancy maintenance. The reduced abundance of Tim-3 on Mφs was accompanied by disordered anti- and pro-inflammatory cytokine profiles in miscarriage. Blockade of Tim-3 or CD132 pathways led to the dysfunction of maternal-fetal tolerance and increased fetal loss. While IL-4 treated Tim-3+ Mφs, via unknown receptor, could rescue the fetal resorption induced by Mφ depletion.

of dMφs [28, 29]. Though Tim-3+ Mφs led to Th2 and Treg bias in dCD4+ T cells and Tim-3− Mφs decreased IL-4, IL-13, GATA-3 and IL-10 expression in dCD4+ T cells, our FCM results and extensive microarray analysis further confirmed that Tim-3+ nor Tim-3− dMφs population can be categorized as strictly M1 or M2. With higher CD132 expression, Tim-3+ dMφs induced Th2 and Treg bias in dCD4+ T cells and promoted pregnancy maintenance. The reduced abundance of Tim-3 on Mφs was accompanied by disordered anti- and pro-inflammatory cytokine profiles in miscarriage. Blockade of Tim-3 or CD132 pathways led to the dysfunction of maternal-fetal tolerance and increased fetal loss. While IL-4 treated Tim-3+ Mφs, via unknown receptor, could rescue the fetal resorption induced by Mφ depletion.
interaction dependent on IL-4 and IL-10 [14, 34, 35]. Whether IL-4 and IL-10 are involved in pregnancy and no history of spontaneous abortions, (terminated for non-medical reasons, had at least one successful trimester pregnancies were obtained from clinically normal pregnancies. Whole peripheral blood, villous and decidual tissues of human pregnancy and no history of spontaneous abortions, (terminated for non-medical reasons, had at least one successful trimester pregnancies were obtained from clinically normal pregnancies.

**Human samples**

Whole peripheral blood, villous and decidual tissues of human first-trimester pregnancies were obtained from clinically normal pregnancies (terminated for non-medical reasons, had at least one successful trimester pregnancies were obtained from clinically normal pregnancies). TIM-3+ T cells were isolated by magnetic af

**Flow cytometry**

Cell surface molecular expression and intracellular cytokine production were evaluated using flow cytometry. FITC-conjugated anti-human CD14, CD4, and isotype mouse F4/80, CD4, TNF-α, IFN-γ, eFluo® 488-conjugated anti-human Foxp3, anti-mouse Foxp3, TNF-α, STAT-1 Phospho, Brilliant Violet 510-conjugated anti-mouse GATA-3, anti-mouse Foxp3, anti-mouse F4/80, TNF-α, GATA-3, STAT-6 Phospho, Pacific Blue-conjugated anti-mouse STAT-1 Phospho, Brilliant Violet 421-conjugated anti-human IL-4, anti-mouse CD206, TNF-α, IL-10, NF-κB, STAT-1 Phospho, Brilliant Violet 510-conjugated anti-mouse CD4, CD68, TNF-α, IFN-γ, Brilliant Violet 605-conjugated anti-mouse CD4, IL-17A (BioLegend, U.S.A.), and PerCP-eFluor-710-conjugated anti-mouse TIM-3, IL-4, TNF-α, IL-12, TNF-α, F4/80, PerCP-Cy5.5-conjugated anti-mouse TIM-3, IL-17A, APC-conjugated anti-human TIM-3, IFN-γ, IL-13, ROR-γt, Foxp3, anti-mouse F4/80, TNF-α, Tim-3, IL-10, ROR-γt, GATA-3, STAT-6 Phospho, Pacific Blue-conjugated anti-mouse STAT-1 Phospho, Brilliant Violet 421-conjugated anti-human IL-4, anti-mouse CD206, TNF-α, IL-4, NF-κB, STAT-1 Phospho, Brilliant Violet 510-conjugated anti-mouse CD4, CD68, TNF-α, IFN-γ, Brilliant Violet 605-conjugated anti-mouse CD4, IL-17A (BioLegend, U.S.A.), and PerCP-eFluor-710-conjugated anti-mouse GATA-3, (eBioscience, San Diego, CA, USA) antibodies were used. For intracellular staining, cells were fixed and permeabilized using the Fix/Perm kit (BioLegend, U.S.A.). Flow cytometry was performed on a Beckman-Coulter CyAn ADP cytometer (Beckman-Coulter, U.S.A.) and analyzed with FlowJo software (Tree Star, Ashland, U.S.A.).

**Statistical analysis**

All variables were normally distributed in this study. Thus, variables were presented as means and standard deviation (SD). One-way analysis of variance (ANOVA) was used to evaluate inter-group differences. A p value of less than 0.05 was considered statistically significant. For variables with a p value of less than 0.05 in ANOVA, the post-hoc Dunnett t-test was performed to determine differences between each group. All analyses were carried out using the GraphPad Prism 8 software (GraphPad, San Diego, CA).

**MATERIALS AND METHODS**

**Ethical approval**

This study was approved by the Research Ethics Committee of the Obstetrics and Gynecology Hospital, Fudan University (No. Kyy2017-50). Every participant signed a written informed consent form. All of animals were conducted in accordance with the National Guidelines for Animal Care and Use in Research (China). The experimental methods in particular were carried out in accordance with the approved guidelines.

**Human samples**

Whole peripheral blood, villous and decidual tissues of human first-trimester pregnancies were obtained from clinically normal pregnancies (terminated for non-medical reasons, had at least one successful pregnancy and no history of spontaneous abortions, (terminated for non-medical reasons, had at least one successful trimester pregnancies were obtained from clinically normal pregnancies). Whole peripheral blood samples were also obtained from normal non-pregnant women of childbearing age (N = 9). PBMCs were isolated from peripheral blood samples using Ficoll density gradient centrifugation (Huaing, China). Tros were isolated by trypsin-DNase I (Applichem, Germany) digestion and discontinuous Percoll gradient centrifugation from the villus tissues as described previously [14]. DCs and DSCs were obtained from the decidual tissue digesting in RPMI 1640 (HyClone, U.S.A) supplemented with collagenase type IV (1.0 mg/ml, CLS-1, Worthington BioMedical, U.S.A.) and DNase I (100 U/ml, Applichem, Germany) as described previously [14]. CD14+ cells were isolated by magnetic affinity cell sorting using CD14 microbeads (MiltenyiBiotec, Germany). TIM-3+ Mps and TIM-3+ MPs were isolated by BD FACSARia™ III Cell Sorter using FITC-conjugated anti-human CD14 antibody, PE-conjugated anti-human TIM-3 antibody. CD4+ T cells were isolated by magnetic affinity cell sorting using CD4 microbeads (MiltenyiBiotec, Germany) or by BD FACSARia™ III Cell Sorter using FITC-conjugated anti-human CD4 antibody.

**Cell Treatment**

Freshly isolated Tros were seeded at a density of 2 × 10^5 cells/ml per well in Matrigel (Coring, U.S.A)-coated 24-well plates overnight. The cells were then washed twice with phosphate-buffered saline (PBS, HyClone, U.S.A). Equal numbers of dCD14+ cells or pCD14+ cells were added to each well. In some wells, anti-HLA-C (10 μg/ml, clone W6/32, Biologend, U.S.A.) or HLA-G (10 μg/ml, clone W1/25, Biologend, U.S.A.) were added. dCD14+ cells were also cultured with HTR8/Svneo cells (ATCC, www.atcc.org) or DSCs for 48 h. In some wells, dCD14+ cells (2 × 10^5 cells) were plated in the upper chamber (0.4 mm pore size cell culture inserts, Millipore, Germany), while Tros were plated in the lower chamber to establish indirect cell contact. Freshly isolated dCD4+ T cells co-cultured with TIM-3+ dMps or TIM-3+ dMps at a 1:1 ratio. In some experiments, TIM-3+ dMps were pretreated with anti-Tim-3 (10 μg/ml, clone F38-2E2, BioLegend, USA) or anti-Tim-3+ dCD132 (10 μg/ml, clone TUGH4, BioLegend, U.S.A.), or anti-IL-4 (10 μg/ml, clone F38-2E2, BioLegend, USA). Phorbol 12-myristate 13-acetate (PMA) (50 ng/ml, BioLegend, U.S.A.), ionomycin (1 μg/ml, BioLegend, U.S.A.) and brefeldin A (10 mg/ml, BioLegend, U.S.A.) were added 4 h before the end of the 48 h co-culture. The supernatants were then collected for intracellular cytokine analysis of T cells.

**RNA-Seq data analysis**

The total RNA of sorted TIM-3+ dMps or TIM-3+ dMps was lysed and extracted according to the protocol of the RNeasy Mini Kit (Qiagen, Germany). Purity and integrity of the extracted RNA was tested by an Agilent Bioanalyzer 2100 (Agilent Technologies, U.S.A.). The prepared libraries were sequenced on an Illumina Hi-seq 2500 platform. Sequenced reads were aligned to the human reference genome using the STAR software package. Exons from all gene isoforms were merged to create one meta-gene. The number of reads failing in the exons of this meta-gene was counted using HTSeq-count, and differential expression analysis was conducted using DE-Seq, P < 0.05 were considered as the significance threshold [28, 37].

**Mice**

CBA/J female, DBA/2 male, and BALB/c male mice were purchased from Slac laboratory animal Co. (Shanghai, China) and Hufuakung bioscience Co. (Beijing, China) and maintained in an animal facility according to institutional and National Institutes of Health Guidelines. Eight-week-old CBA/J females were mated to BALB/c males to induce normal pregnancy (NP). Eight-week-old CBA/J females were mated to DBA/2 males to establish abortion-prone (AP) models. All the CBA/J females were inspected every morning for vaginal plugs. The day of visualization of a plug was designated as day 0.5 of pregnancy (GD 0.5). Some pregnant females of NP received injections of anti-Tim-3 antibody (clone RTM3-23, BioLegend, U.S.A.) or isotype IgG i.p at doses of 500, 250, and 250 mg on days 4.5, 6.5, and 8.5, respectively based on our previous publication [14]. For Mπ depletion and Mπ adoptive transfer in pregnant CBA/J mice, Clodronate Liposomes were injected intraperitontenally at day 0.5 (200 μl) and day 3.5 (100 μl) of gestation. Tim-3+ Mps or Tim-3+ Mps were isolated from the spleen of C57BL/6 mice with an NP (GD 7.5) by BD FACSARia™ III Cell Sorter and labeled with PKH-67 or not. The sorted cells were then resuspended in 200 ml of PBS and injected into the tail vein of Mπ-depleted pregnant mice at GD4.5. In some groups, Tim-3+ Mps were pre-stimulated with anti-CD132 (10 μg/ml, clone TUGm2, BioLegend, U.S.A.) or anti-IL-4 (10 μg/ml, clone 11B11, BioLegend, U.S.A.), Tim-3+ Mps were pre-stimulated with IL-4 (10 ng/ml, PeproTech, U.S.A.) for 4 h. Pregnant mice were infected at GD0.5. The percentage of fetal loss (the embryo absorbption rate) was calculated as following: % of resorption = R / (R + V) × 100, where R represents the number of hemorrhagic implantation (sites of fetal loss) and V stands for the number of viable, surviving fetuses. Uteri from pregnant mice were dissected free from the mesometrium and removed by cuts at the ovaries and cervix. The fetal and placental tissues were carefully removed and washed in PBS. Minced uteri were digested in RPMI 1640 supplemented with collagenase type IV and DNase I for 45-60 min at 37 °C with gentle agitation. Cells were cultured in RPMI 1640 supplemented with 10% FBS, 100 U/ml penicillin, 100 μg/ml streptomycin, and 1 μg/ml amphotericin B at 37 °C in 5% CO2 for 4 h to remove adherent stromal cells. The spleen was aseptically excised and stored in RPMI 1640. A single-cell suspension was made by using a 10 μl syringe plunger to pass spleen tissue into fresh wash medium through a 70-μm mesh strainer. PMA (50 ng/ml, BioLegend, U.S.A.), ionomycin (1 μg/ml, BioLegend, U.S.A.) and brefeldin A (10 mg/ml, BioLegend, U.S.A.) were added 4 h for intracellular cytokine analysis of T cells.
