Overexpression of Betaig-h3 gene downregulates integrin α5β1 and suppresses tumorigenicity in radiation-induced tumorigenic human bronchial epithelial cells

Interaction between cell and extracellular matrix plays a crucial role in tumour invasion and metastasis. Using an immortalised human bronchial epithelial (BEP2D) cell model, the study here shows that expression of Betaig-h3 gene, which encodes a secreted adhesion molecule induced by transforming growth factor-β, is markedly decreased in several independently generated, radiation-induced tumour cell lines (TL1–TL5) relative to parental BEP2D cells. Transfection of Betaig-h3 gene into tumour cells resulted in a significant reduction in tumour growth. While integrin receptor α5β1 was overexpressed in tumour cells, its expression was corrected to the level found in control BEP2D cells after Betaig-h3 transfection. These data suggest that Betaig-h3 gene is involved in tumour progression by regulating integrin receptor α5β1. The findings provide strong evidence that the Betaig-h3 gene has tumour suppressor function in human BEP2D cell model and suggest a potential target for interventional therapy.

Keywords: Betaig-h3; tumour suppression; human bronchial epithelial cells; integrin receptor

Tumour growth and metastasis is a multistep process involving cell adhesion, extracellular matrix (ECM) degradation and cell migration (Tlsty, 1998). The integrin superfamily consists of a major class of transmembrane glycoproteins that mediate cell–ECM and cell–cell adhesion (Giancotti and Ruoslahti, 1999). Loss or gain of expression of specific integrin has been implicated in malignant transformation, tumour progression and metastasis (Mizejewski, 1999). There is evidence that osteosarcoma cells that overexpress integrin α5β1 show reduced invasive potential (Giancotti and Ruoslahti, 1990). In contrast, upregulation of α5β1 has been shown to correlate with invasive phenotype in colon cancer and transitional cell carcinoma (Saito et al., 1996; Gong et al., 1997). Similarly, recent data show that high levels of integrin α6 in breast cancer and αvβ3 in melanoma correlate with tumour progression (Mukhopadhyay et al., 1999; Hofmann et al., 2000). Therefore, depending on the cell type and tumour model, expression of various integrin subunits may contribute either positively or negatively to the transformed phenotype.

Betaig-h3 is a secreted protein induced by transforming growth factor-β (TGF-β) in human adenocarcinoma cells as well as other human cell types (Skonier et al., 1992). Although transfection of Betaig-h3 gene into CHO (Chinese Hamster Ovary) fibroblasts markedly reduces their ability to form tumours in nude mice (Skonier et al., 1994), its expression as well as regulation in human tumour has not been examined until now. There is evidence that mutations or altered expression of this gene are involved in corneal dystrophy and osteogenesis in human (Bron, 2000; Kim et al., 2000a). In addition, Betaig-h3 protein is a component of ECM in lung, bladder and skin (LeBaron et al., 1995; Billings et al., 2000a,b), which promotes adhesion and the spreading of dermal fibroblasts in vitro and mediates cell adhesion by interacting with α3β1 integrin in human corneal epithelial cells (Billings et al., 2000b; Kim et al., 2000b). These data suggest that Betaig-h3 protein is involved in cellular adhesion and imply an important role of this gene in the process of human tumour progression.

Although in vitro transformation studies with human cells are highly desirable in studying the molecular events associated with malignant conversion, such studies, thus far, have not been successful with primary human epithelial cells (Hei et al., 1994). Using papillomavirus-immortalised human bronchial epithelial (BEP2D) cells, we have previously shown that α5β1 particles can malignantly transform these cells in a stepwise fashion before they become tumorigenic and metastatic in nude mice. It should be stated that although these cells are immortalised, they do not possess any other transformed phenotypes and only after carcinogen treatment, and extended subculturing, do transformed/tumorigenic phenotypes emerge in a sequential fashion (Hei et al., 1994, 1996). The BEP2D cell model is, therefore, useful in studying the genetic events involved in tumour progression. In the present study, we show that ectopic expression of Betaig-h3 gene in radiation-induced tumour cells significantly suppresses their in vivo tumorigenicity. This finding provides strong evidence that Betaig-h3 has tumour suppressor function in human BEP2D cells.

MATERIALS AND METHODS

Cell culture

Tumorigenic BEP2D cells were derived previously from treatment of exponentially growing BEP2D cells with a single
Betaig-h3 inhibits tumorigenicity of human bronchial epithelial cells

YL Zhao et al

60 cGy dose of alpha-particles (Hei et al, 1996). Tumours larger than 1 cm in diameter were resected from nude mice and used to establish independently-generated cell lines (TL1–TL5). The BEP2D cells and tumour cell lines were maintained in serum-free LHC-8 medium supplemented with growth factors as described previously (Hei et al, 1994). Primary human bronchial epithelial (NHBE) cells were purchased from Clonetics (catalogue no: CC-2541) and grown in BEGM medium (Clonetics).

cDNA array and Northern blotting

cDNA array (Clontech) was hybridised with 32P-labelled cDNA probes prepared by reverse transcription using 1 μg mRNA from control BEP2D and TL1 tumour cells as described previously (Zhao et al, 2001). The hybridisation signals were analysed by autoradiography and further quantified by phosphorimaging (ImageQuant software). The expression levels of β-actin and G3PDH housekeeping genes were used as standards for normalising the expression levels of other genes.

For Northern blot, 2.5 μg of mRNA was denatured and separated on a 1% denaturing agarose formaldehyde gel. The mRNAs were then transferred on nylon membrane (Millipore Corp., Bedford) by downward capillary blotting in 20 × SSC (3 M NaCl, 0.3 M Na₂Citrate-2H₂O, pH 7.0) followed by UV cross-linking. Specific probe was generated by labelling of PCR-amplified cDNA fragments with [α-32P]dCTP using random primed DNA labelling kit (Boehringer, Mannheim). The membranes were pre-hybridised for 30 min and then hybridised with cDNA probe in ExpressHyb TM hybridisation solution (Clontech) for 8–12 h at 68°C. The blots were washed twice in 2× SSC, 0.1% SDS at room temperature for 15 min followed by washing twice in 0.2× SSC, 0.1% SDS at 55°C for 15 min. The membranes were exposed to Kodak BioMax film at −70°C for 12–72 h. The band intensities were evaluated by phosphorimaging and normalised to β-actin expression level.

All probes for Northern blot were acquired by PCR amplified gene fragments using the following primer sets: α5: 5’-AGAGCCCAAAATGCTGACATTG-3’, 5’-CTGGAGGCTGACAGTGACCT-3’; β1: 5’-GTTGTTCAAGTCAGAGCCCTCA-3’, 5’-CTTGGAGTTGACCCAGAT-3’; β-actin: 5’-GTGCTATCCAGCTGTGC-3’, 5’-GCATCGTCTGCGCAATGC-3’.

Cloning and sequencing of Betaig-h3 cDNA

The first strand cDNA was synthesised from 0.2 μg poly(A)+ RNA isolated from NHBE cells using Superscript II reverse transcriptase and oligo(dt) primer (Gibco). Human Betaig-h3 cDNA was then PCR-amplified using high-fidelity MasterAmp™ DNA polymerase (Epicenter, Madison, WI, USA) and synthetic primers (5’-GTTAAGCTTGCTGCGTCGTCAGTGCT-3’, 5’-GCTCTAGAGCCCTCAAGGAGCTGTAGTATG-3’) that included HindIII and XbaI restriction enzyme recognition sites. The amplified whole length cDNA was subcloned into the HindIII and XbaI-digested pRc/CMV2 expression vector (Invitrogen). The sequence analysis showed that the protein sequence is 100% identical with that reported in GeneBank (accession no: M77349) with the exception of several modified nucleotide sites such as 698 (C→T). Control animals were inoculated with either control BEP2D cells or with radiation-induced TL1 tumour cells. For each cell line, two independent experiments were performed.

RESULTS

Betaig-h3 is downregulated in radiation-induced tumour cell lines

Tumorigenic BEP2D cells were established by exposing the non-tumorigenic, immortalised parental cells to a single 60 cGy dose of α-particles as described (Hei et al, 1996). A series of primary and secondary tumour cell lines (TL1–TL5) were established from tumour nodules developed in nude mice. By using cDNA array techniques, a series of genes were identified that were differentially expressed in radiation-induced tumour cells relative to parental BEP2D cells (Zhao et al, 2001). Among these genes, Betaig-h3 expression was markedly decreased in tumour cells (Figure 1A). The result was further confirmed by Northern blot using mRNAs obtained from different passages of transformed cells and five tumour cell lines (Figure 1B). In early-passaged cells (1 week after radiation), no change in Betaig-h3 expression was found when compared with control BEP2D cells. However, the expression of Betaig-h3 was downregulated by 2.4-fold in late-passaged cells (just before inoculating into nude mice) and between 7.5–9-fold in all five tumour cell lines examined. These results indicate that decreased expression of Betaig-h3 gene might be related to the acquisition of malignant phenotype in BEP2D cells.
Overexpression of Betaig-h3 gene in tumour cells suppresses their colony-forming efficiency in soft agar and tumorigenicity in nude mice

To examine the significance of Betaig-h3 downregulation in malignant conversion, we recovered the expression of Betaig-h3 gene in a representative tumour cell line (TL1) with pRc/CMV2-Betaigh3 vector. Two G418-resistant colonies (TL1-clone 18 and TL1-clone 28) that expressed different levels of Betaig-h3 were chosen for further studies. From the Northern and Western blot results (Figure 2A), the parental TL1 and TL1-pRc/CMV2 cells (vector control) expressed similar levels of Betaig-h3, which were lower than control BEP2D cells. After Betaig-h3 transfection, the expression of this gene in TL1-clone 18 was recovered to a level similar to that of control BEP2D cells, whereas TL1-clone 28 had a four-fold higher expression level. Expression of the Betaig-h3 gene in primary human bronchial epithelial (NHBE) cells and control BEP2D cells, on the other hand, was similar both at the mRNA and protein levels (Figure 2A).

TL1-clone 18 and TL1-clone 28 cells grew much slower and showed lower saturation density than parental TL1 tumour cells (Figure 2B). The doubling time of cells transfected with the empty vector was 32 h, which was similar to that of TL1 tumour cells. In contrast, clone 18 and 28 cell lines grew slower than TL1, with doubling times of about 55 h. We also checked their colony-forming efficiency in soft agar (Table 1). The result showed that there was no significant difference between parental TL1 and TL1-pRc/CMV2 cells (2.39 and 2.28%, respectively with a P > 0.05). However, TL1-clone 18 and TL1-clone 28 cells resulted in a significantly lower ability of anchorage independent growth with colony-forming efficiency in agar of 0.29 and 0.34%, respectively (P < 0.01).

To determine whether ectopic expression of the Betaig-h3 gene suppresses tumour formation in vivo, 5 × 10⁶ of each of the following cell types were subcutaneously injected into nude mice: control BEP2D cells, TL1 tumour cells, TL1-pRc/CMV2 and TL1-clone 18 and TL1-clone 28. The tumour volumes were measured weekly during the experiments. As shown in Table 1, no tumours (zero out of eight mice) were found in parental BEP2D cells after monitoring for more than 20 weeks. However, eight out of eight mice that were injected with either TL1 or TL1-pRc/CMV2 tumour cells developed progressively growing tumours with average volumes of 1021.8 ± 330.7 mm³ and 970.6 ± 295.6 mm³, respectively. In contrast, four out of eight mice with TL1-clone 18 and five out of eight mice with TL1-clone 28 cells formed only small nodules. The volume, which averaged 86.7 ± 32.3 mm³, was significantly smaller than that of parental TL1 tumour cells (P < 0.01). Meanwhile, tumour growth was significantly suppressed in tumour cells after Betaig-h3 transfection (Figure 2C).

Betaig-h3 gene is related to the expression level of integrin receptor α5/1

Previous studies have suggested that Betaig-h3 protein affects cell–ECM interaction through regulation of integrin receptor (LeBaron et al., 1995; Billings et al., 2000a,b). Using cDNA array, it was found that the expression of this gene in TL1-clone 18 was recovered to a level similar to that of control BEP2D cells, whereas TL1-clone 28 had a four-fold higher expression level. Expression of the Betaig-h3 gene in primary human bronchial epithelial (NHBE) cells and control BEP2D cells, on the other hand, was similar both at the mRNA and protein levels (Figure 2A).

Table 1 Suppression of anchorage-independent growth and tumorigenicity by Betaig-h3 gene

| Cell type | CFE in soft agar (%) | Tumours/total mice | Tumour volume at 4 weeks (mm³) |
|-----------|---------------------|-------------------|-----------------------------|
| BEP2D cells | 0.02 | 0/8 | – |
| TL1 tumour cells | 2.39 ± 0.29 | 8/8 | 1021.8 ± 330.7 |
| TL1-pRc/CMV2 | 2.28 ± 0.37 | 8/8 | 970.6 ± 295.6 |
| TL1-Betaig-h3 clone 18 | 0.29 ± 0.05* | 4/8 | 86.7 ± 32.3* |
| TL1-Betaig-h3 clone 28 | 0.34 ± 0.07* | 5/8 | – |

*P < 0.01, compared with parental tumour cells. **CFE, Colony Forming Efficiency. The colonies in soft agar were counted and tumour volumes were measured as described in Materials and Methods. αP < 0.01, compared with parental tumour cells.
that \( \alpha5 \beta1 \) integrin receptor was overexpressed in radiation-induced tumour cells (data not shown). To determine whether the expression of integrin receptor \( \alpha5 \beta1 \) correlated with \( \text{Betaig-h3} \) gene expression, we checked its mRNA and protein levels in parental TL1 and TL1-transfected tumour cells. As shown in Figure 3, expression of \( \alpha5 \) and \( \beta1 \) subunits was five- and three-fold higher, respectively, in parental TL1 and TL1-pRc/CMV2 cells than in control BEP2D cells. However, after transfecting \( \text{Betaig-h3} \) gene into TL1 tumour cells, expression of \( \alpha5 \beta1 \) integrin (clone 18 and 28 cells) decreased to level of control BEP2D cells. This data were further confirmed by immunoprecipitation using monoclonal antibody for \( \alpha5 \) and \( \beta1 \). We further checked the mRNA expression of integrin subunits \( \alpha1-\alpha4, \alpha6, \alpha v \) and \( \beta2-\beta3 \). No significant changes in their expression were found among control BEP2D, TL1 tumour cells and \( \text{Betaig-h3} \)-transfected TL1 tumour cells (data not shown).

**DISCUSSION**

In an attempt to identify genes involved in the progression of lung carcinoma, cDNA arrays were used to screen differentially expressed genes between control BEP2D and radiation-induced tumour cells. Altered expression of a series of genes that controlled cellular growth and differentiation between these two cell models was found (Zhao et al., 2001), with \( \text{Betaig-h3} \) gene notably down-regulated in tumour cells, a finding that was further confirmed in five tumour cell lines by Northern blot. Previous studies have shown that \( \text{Betaig-h3} \) gene expression is significantly reduced in embryonal rhabdomyosarcoma cell lines and mesenchymal tumours (Genni et al., 1996; Schenker and Trueb, 1998), suggesting that \( \text{Betaig-h3} \) may have an important role in human cancer. Although overexpression of this gene in CHO fibroblast cells leads to a marked decrease in their ability to form tumour in nude mice (Skonier et al., 1994), little is known about its regulation in tumour progression of human tissues. In this study, we provide evidence that ectopic expression of \( \text{Betaig-h3} \) in TL1 tumour cells significantly inhibits colony-forming efficiency in soft agar, and tumour growth in nude mice relative to parental tumour cells. This is the first evidence that \( \text{Betaig-h3} \) gene has tumour suppressor function in a human epithelium-derived tumour model.

\( \text{Betaig-h3} \) is a secreted protein that promotes the adhesion of dermal fibroblasts and corneal epithelial cells (LeBaron et al., 1995; Billings et al., 2000a,b). These findings imply that \( \text{Betaig-h3} \) gene affects cell–ECM interaction by regulating integrin receptors. This study confirms that acquisition of tumorigenic phenotype of BEP2D cells is accompanied by an increased expression of \( \alpha5 \beta1 \) integrin receptor at both the mRNA and protein levels. Ectopic expression of \( \text{Betaig-h3} \) gene in tumorigenic cells (TL1) led to downregulation of integrin and suppression of tumorigenicity. The data suggest that \( \text{Betaig-h3} \) gene is involved in the tumorigenic process by regulating \( \alpha5 \beta1 \) expression. The observation is consistent with other reports that \( \alpha5 \beta1 \) while...
undetectable in normal lung epithelial, is significantly elevated in SV40 large T-transformed human bronchial epithelial cells (Albeda et al., 1999). Schiller and Bittner (1995). In non-small lung carcinoma, cells, higher levels of α5β1 integrin expression represents a negative prognostic factor (Adachi et al., 2000). Similar results have also been shown with other human tissues that high levels of α5β1 integrin is associated with more malignant phenotype in melanoma, transitional and colon cell carcinomas (Saito et al., 1996; Gong et al., 1997; Beliveau et al., 2000). The α5β1 integrin favours cell survival and protects cells from apoptosis in vitro via upregulation of anti-apoptotic Bcl-2, whereas resistance to apoptosis is a feature of many malignant cells (Zhang et al., 1995). These data, together with our results, suggest a key role for α5β1 overexpression in tumorigenicity of human bronchial epithelial cells. Although there is evidence that the Betaig-h3 protein mediates cell adhesion by interacting with α5β1 (Kim et al., 2000b), integrins are expressed in a cell-type- and stage-specific manner (Ruoslahti, 1999). Examples of cell-type-specific integrins include α1β1αβ3 in platelets and α6β4 in epithelial cells. One group of integrins is associated with migration and proliferation in various types of cells. These ‘emergency integrins’ which include α5β1, αvβ3, and αvβ6 (Sheppard, 1996) are particularly important in cancer. However, no differential expression of α1–α4, α6, αv and β2–β3 integrin subunits was found between Betaig-h3 transduced and parental TL1 tumour cells. The data suggest that Betaig-h3 gene is involved in tumour progression of human bronchial epithelial cell model by regulating integrin receptor α5β1.

Altered cell–matrix interaction is an essential prerequisite step in the invasive and metastatic cascade (Hart and Saini, 1992). Our finding that normal NHBE and immortalised BEP2D cells exhibit similar levels of Betaig-h3 expression suggests that loss of its expression occur during late stage of tumour progression. Previous data show that chromosome 5q31, where Betaig-h3 gene has been regionally mapped to, is often deleted in leukemias, myelodysplastic syndromes and many human cancer such as renal cell, oesophageal and lung carcinomas (Peralta et al., 1998; Wu et al., 1998; Brezinova et al., 2000). These findings suggest that deletion of Betaig-h3 gene is a frequent event in human cancer. The question of whether reexpression of Betaig-h3 gene in human tumour cell lines may result in suppression of tumorigenicity is currently under investigation. Our present finding suggest that Betaig-h3 gene could be a novel diagnostic marker of tumour metastasis and a potential target for cancer therapy.

ACKNOWLEDGEMENTS
The authors thank Dr Paul C Billings for kindly providing anti-Betaig-h3 antibody, and Drs Vicente Notario and Takaaki Sato for helpful discussions. Work supported in part by RSNA grant SD0133 and National Institute of Health grants CA49062 & ES07890.
