Abstract

In this paper a new method of experimental data analysis, the Particle-Set Identification method, is presented. The method allows to reconstruct moments of multiplicity distribution of identified particles. The difficulty the method copes with is due to incomplete particle identification - a particle mass is frequently determined with a resolution which does not allow for a unique determination of the particle type. Within this method the moments of order k are calculated from mean multiplicities of k-particle sets of a given type. The PSET Identification method remains valid even in the case of correlations between mass measurements for different particles. This distinguishes it from the Identity method introduced by us previously to solve the same problem.

I. INTRODUCTION

Study of multiplicity fluctuations of identified particles produced in high energy nucleus-nucleus collisions is motivated by a number of important physics issues. They include searching for the critical point of strongly interacting matter, uncovering properties of hadronization and testing the validity of statistical models beyond mean multiplicities of identified hadrons, see Refs. [1, 2] for details. Experimental measurements of multiplicity distributions of identified hadrons are challenging because it is often impossible to identify a particle with sufficient precision. Typical tracking detectors, like time projection chambers or silicon pixel detectors, used in high energy physics, allow for a precise measurement of momenta of charged particles and sign of their electric charges. In order to be able to distinguish between different particle types (e.g. $e^+$, $\pi^+$, $K^+$, proton) a determination of particle mass is necessary. This is done indirectly by measuring for each particle the value of special variable, e.g., specific energy loss, $dE/dx$, time-of-flight or the Cerenkov radiation angle. In the following text this variable is called the "mass" variable. In 2011 the Identity method [3] was proposed as a tool to measure moments of multiplicity distribution of identified particles, which circumvents the experimental issue of incomplete particle identification. The method was significantly developed in Ref. [4] and extended in following papers, see Refs. [5–8]. Currently, the Identity Method is used by several experimental collaborations [9–12].

In this paper we present a novel approach, the Particle-Set (PSET) Identification method, for reconstructing moments of multiplicity distribution of identified particles. Hereinafter a PSET represents a set of $k$-particles which is constructed from particles created in a collision. For example, in the simplest non-trivial case of two particle types, pions and kaons, three types of two-particle sets are possible: pion-pion, kaon-kaon and pion-kaon. Mean multiplicities of different two-particle sets permit to calculate the second order moments of the joint multiplicity distribution of pions and kaons. To find the third order (in general, $k^{th}$ order) moments of the multiplicity distribution one needs mean multiplicities of three-particle (in general, $k$-particle) sets. The latter are obtained from fits to the $k$-dimensional distribution of particle masses. The PSET Identification method has a broader range of applicability than the Identity method. Particularly, it does not assume that measurements of mass for different particles are
independent.

The paper is organized as follows. Section II introduces the PSET Identification method. For simplicity, the presentation in this section is restricted to second moments of the multiplicity distribution of two particle types, pions and kaons. First, the problem is defined and the well-known method to calculate mean multiplicities of identified hadrons is reviewed. Then an extension of this method needed to calculate second moments is presented. In Sec. III a general formulation of the method is sketched. This allows to deal with an arbitrary number of particle types as well as to calculate higher than second moments. Section IV closes the paper.

II. INTRODUCTION TO PSET IDENTIFICATION METHOD

The resolution of the ”mass” variable, denoted as $x$, is usually poor – often probabilities to register particles of different types in the same interval of $x$ are comparable. Consequently, it is impossible to identify particles individually with a reasonable confidence level. However, it can still be possible to extract information on average production properties of particles of a given type, such as mean multiplicity of single particles or, in general, mean multiplicity of particle sets of a given type.

The resolution of the ”mass” variable measurement for single particles of type $a$ is quantified by the probability density function (pdf) $f_a(x, p)$. In general, the function depends also on the particle momentum vector $p$ which complicates the data analysis. Detector properties, data calibration and analysis procedures determine the pdf $f_a(x, p)$.

When pairs of particles are of interest, the single particle pdf is replaced by a two-particle probability density function, $f_{ab}((x_1, p_1), (x_2, p_2))$, where $a$ and $b$ are particle types of the first and second particle, respectively. Single particle pdfs are related to two-particle pdfs as

$$f_a(x_1, p_1) = \int dx_2 dp_2 f_{ab}((x_1, p_1), (x_2, p_2)).$$

In general, the two-particle pdf cannot be represented as a product of the single particle pdfs: $f_{ab}((x_1, p_1), (x_2, p_2)) \neq f_a(x_1, p_1) \cdot f_b(x_2, p_2)$. The reason are correlations which are caused by detector and data calibration properties (e.g., a finite two track resolution and/or time dependent response) as well as by the analysis procedure (e.g., neglecting the $p$-dependence of the pdfs within the momentum bins used in the analysis).
For clarity, the PSET Identification method is introduced here using the following simplifying assumptions:

(i) There are only two particle types: positively charged pions and kaons which for simplicity are referred to as pions and kaons, and denoted as $\pi$ and $K$, respectively.

(ii) The single-particle and two-particle pdfs are independent of particle momenta, i.e.,

$$f_a(x,p) = f_a(x) \quad \text{and} \quad f_{ab}((x_1,p_1),(x_2,p_2)) = f_{ab}(x_1,x_2), \quad \text{for} \ a,b = \pi,K.$$

(iii) The pdfs $f_a(x)$ and $f_{ab}(x_1,x_2)$ are assumed to be known.

The extension of this simple model to an arbitrary number of particle types as well as to higher moments of multiplicity distribution is discussed in the next section.

A. Mean multiplicities of identified hadrons

Let us assume that an experiment measured particles produced in $M$ collisions (events). The set of $x$ values measured for the $N_i$ particles in an event $i$ is denoted as $X_i = \{x_1,x_2,...,x_{N_i}\}$. The total number of particles measured in $M$ events is

$$N = \sum_{i=1}^{M} N_i,$$  \hspace{1cm} (2)

and the mean particle multiplicity (sum of pions and kaons) can be calculated as

$$\langle N \rangle = \frac{N}{M}. \hspace{1cm} (3)$$

The full set of $x$-measurements is denoted as $\mathcal{X} = \{x_1,x_2,...,x_N\}$.

Statistical tools to extract mean multiplicities of identified hadrons and its momentum dependence (single particle spectra) are presented and discussed in detail in Ref. [13]. Here the general solution [13] is adapted to the simple model introduced in this section.

The distribution of the sum of pions and kaons in the ”mass” variable $x$ is given by

$$\rho(x) \equiv \rho_{\pi}(x) + \rho_{K}(x) \equiv \langle N_{\pi} \rangle \cdot f_{\pi}(x) + \langle N_{K} \rangle \cdot f_{K}(x) \equiv \langle N \rangle \left( r_{\pi} \cdot f_{\pi}(x) + r_{K} \cdot f_{K}(x) \right), \hspace{1cm} (4)$$

where $f_{\pi}(x)$ and $f_{K}(x)$ are the known pdfs of pions and kaons, respectively.
Mean multiplicities of pions $\langle N_\pi \rangle$ and kaons $\langle N_K \rangle$ are unknown and should be extracted from the experimental data $X = \{x_1, x_2, ... x_N\}$. They are equal to $\langle N_\pi \rangle = r_\pi \cdot \langle N \rangle$ and $\langle N_K \rangle = r_K \cdot \langle N \rangle$ with $\langle N \rangle$ calculated from the data as given by Eq. 3. By definition $r_\pi + r_K = 1$ and consequently, only one parameter, e.g. $r_K$, should be estimated from the data $X$. Finally we note that the function

$$F(x) = r_\pi \cdot f_\pi(x) + r_K \cdot f_K(x)$$

is the pdf for the system of pions and kaons.

An example distribution of the "mass" variable $x$, $\rho(x)$ (Eq. 4), for a system of pions and kaons is presented in Fig. 1 left. The overlap of the $f_\pi(x)$ and $f_K(x)$ pdfs does not allow to identify a large fraction of particles with a high confidence level.

There are two commonly used parameter estimation methods (see, e.g., Ref. [14]):
(i) the least-squares method (LSM),

(ii) the maximum likelihood method (MLM).

The application of the LSM would require binning of the data points in $x$-space. This has two important disadvantages: the binning procedure causes partial loss of the experimental information, and the binning necessary for the meaningful application of the LSM (number of entries in each bin has to be large enough) may be impossible in the case of low statistics data.

The above problems are not present in the MLM, as it allows to use the unbinned data. Therefore in the following we will briefly introduce the MLM and the way it should be applied here. Let us start from defining the likelihood function (LF):

$$L(\mathbf{X} | r_K) = \prod_{i=1}^{N} F(x_i | r_K) \quad (6)$$

as a joint conditional probability of the measurements $\mathbf{X}$ at the fixed value of the parameter $r_K$. Now, in the LF we treat the measurements $\mathbf{X}$ as fixed values and the parameter $r_K$ as a variable. According to the maximum likelihood principle we should choose a value of $\hat{r}_K$ which maximizes $L(\mathbf{X} | r_K)$. It is usually more convenient to minimize the auxiliary function, $l(\mathbf{X} | r_K)$, defined as:

$$l(\mathbf{X} | r_K) \equiv -\ln \left( L(\mathbf{X} | r_K) \right) = -\sum_{i=1}^{N} \ln \left( F(x_i | r_K) \right). \quad (7)$$

The search for the value of $\hat{r}_K$, which minimizes $l(\mathbf{X} | r_K)$, has to be done using standard numerical minimization procedures [15].

To estimate the statistical uncertainty of $\hat{r}_K$ one should use the sub-sample [16] and/or bootstrap methods [17] at the level of events as independent data units. It is important to stress that both methods take into account correlations between measurements of the "mass" variable for different particles. The goodness-of-fit tests are discussed in detail in Ref. [13].

B. Mean multiplicity of particle pairs

In this subsection the PSET Identification method is considered for particle pairs. Let us start with the observation that the mean multiplicity of pairs of particles of a given type is
directly related to the second moment of its multiplicity distribution. For example, the mean multiplicity of pion-pion pairs, $\langle N_{\pi\pi} \rangle$, is given as:

$$\langle N_{\pi\pi} \rangle = \frac{1}{2} \langle N_\pi (N_\pi - 1) \rangle = \frac{\langle N_\pi^2 \rangle - \langle N_\pi \rangle}{2}. \quad (8)$$

When mean multiplicities of pions, $\langle N_\pi \rangle$, and pion-pion pairs, $\langle N_{\pi\pi} \rangle$, are known, the second moment of the pion multiplicity distribution can be calculated as:

$$\langle N_\pi^2 \rangle = 2 \cdot \langle N_{\pi\pi} \rangle + \langle N_\pi \rangle. \quad (9)$$

In a similar way $\langle N_K^2 \rangle$ and $\langle N_\pi \cdot N_K \rangle$ are calculated. Thus the problem of measuring second moments of joint multiplicity distributions of identified particles reduces to finding mean multiplicities of identified particle pairs.

The experimental data on particle pairs in $M$ events is defined as follows. Number of particle pairs in an event $i$ of multiplicity $N_i$ is

$$N_i^{(2)} = \frac{1}{2} N_i (N_i - 1). \quad (10)$$

The total number of pairs in all $M$ events is

$$\mathcal{N}^{(2)} = \sum_{i=1}^{M} N_i^{(2)}, \quad (11)$$

and the mean multiplicity of all possible pairs can be calculated as

$$\langle \mathcal{N}^{(2)} \rangle = \frac{\mathcal{N}^{(2)}}{M}. \quad (12)$$

The full set of the pair data consists of $\mathcal{N}^{(2)}$ pairs:

$$\mathcal{X}^{(2)} = \{ (x_1, x_2)_1, (x_1, x_2)_2, \ldots, (x_1, x_2)_{\mathcal{N}^{(2)}} \}. \quad (13)$$

The two-particle mass distribution function $\rho(x_1, x_2)$ is a weighted sum of two-dimensional pdfs of identified pairs:

$$\rho(x_1, x_2) \equiv \rho_{\pi\pi}(x_1, x_2) + \rho_{KK}(x_1, x_2) + \rho_{\pi K}(x_1, x_2) + \rho_{K\pi}(x_1, x_2)$$

$$\equiv \langle N_{\pi\pi} \rangle \cdot f_{\pi\pi}(x_1, x_2) + \langle N_{KK} \rangle \cdot f_{KK}(x_1, x_2) + \langle N_{\pi K} \rangle \cdot f_{\pi K}(x_1, x_2) + \langle N_{K\pi} \rangle \cdot f_{K\pi}(x_1, x_2)$$

$$\equiv \langle N^{(2)} \rangle \left( r_{\pi\pi} \cdot f_{\pi\pi}(x_1, x_2) + r_{KK} \cdot f_{KK}(x_1, x_2) + r_{\pi K} \cdot f_{\pi K}(x_1, x_2) + r_{K\pi} \cdot f_{K\pi}(x_1, x_2) \right), \quad (14)$$
with \( r_{\pi\pi} + r_{KK} + 2 \cdot r_{\pi K} = 1 \). Consequently, only two parameters should be estimated from the experimental measurements \( \mathcal{X}^{(2)} \). The two-dimensional probability density function for the system of pions and kaons reads:

\[
F(x_1, x_2 | r_{\pi\pi}, r_{KK}) = r_{\pi\pi} \cdot f_{\pi\pi}(x_1, x_2) + r_{KK} \cdot f_{KK}(x_1, x_2) + r_{\pi K} \cdot f_{\pi K}(x_1, x_2) + r_{\pi K} \cdot f_{K \pi}(x_1, x_2) + r_{\pi p} \cdot f_{\pi p}(x_1, x_2) + r_{p \pi} \cdot f_{p \pi}(x_1, x_2) + r_{p K} \cdot f_{p K}(x_1, x_2) + r_{K p} \cdot f_{K p}(x_1, x_2)
\]

(15)

and using the MLM the auxiliary likelihood function:

\[
l(\mathcal{X}^{(2)} | r_{\pi\pi}, r_{KK}) = - \sum_{i=1}^{N} \ln \left( F \left( (x_1, x_2)_i | r_{\pi\pi}, r_{KK} \right) \right).
\]

(16)

is minimized to determine the parameters \( r_{\pi\pi} \) and \( r_{KK} \). Statistical uncertainties of the fitted parameter values, \( r_{\pi\pi} \) and \( r_{KK} \) are to be estimated following the procedure described in the previous subsection. An example of the \( \rho(x_1, x_2) \) function is presented in Fig. 1 right.

III. PSET IDENTIFICATION METHOD: TOWARDS GENERAL FORMULATION

In this section the results presented in the previous section are extended to three particle types and to third moments of the multiplicity distributions. Then, the extension to higher number of particle types and higher moments is obvious.

In the case of three particle types, for example pions, kaons, and protons, the two-particle "mass" distribution function reads:

\[
\rho(x_1, x_2) = \langle N^{(2)} \rangle \left( r_{\pi\pi} \cdot f_{\pi\pi}(x_1, x_2) + r_{KK} \cdot f_{KK}(x_1, x_2) + r_{pp} \cdot f_{pp}(x_1, x_2) + r_{\pi K} \cdot f_{\pi K}(x_1, x_2) + r_{K \pi} \cdot f_{K \pi}(x_1, x_2) + r_{\pi p} \cdot f_{\pi p}(x_1, x_2) + r_{p \pi} \cdot f_{p \pi}(x_1, x_2) + r_{K p} \cdot f_{K p}(x_1, x_2) + r_{p K} \cdot f_{p K}(x_1, x_2) \right).
\]

(17)

From relations \( r_{ab} = r_{ba} \) and \( \sum_{a,b} r_{ab} = 1 \) it follows that only five parameters are independent. Their values can be found by minimizing the corresponding auxiliary likelihood function, as that in Eq. (16). In a similar way expressions for more than three particle types can be obtained.

Let us now consider third moments of the multiplicity distribution for two particle types, pions and kaons. To calculate them within the PSET Identification method one should first
extract from the data the mean multiplicity of identified three-particle sets. Then the three-dimensional pdfs, \( f_{abc}(x_1, x_2, x_3) \), have to be known. With these functions, the three-particle probability density function \( F(x_1, x_2, x_3 \mid r) \) can be calculated. Here \( r \) denotes a set of unknown independent parameters. Their values should be fitted to the data on particle triplets:

\[
\mathcal{X}^{(3)} = \{(x_1, x_2, x_3)_1, (x_1, x_2, x_3)_2, \ldots, (x_1, x_2, x_3)_{N^{(3)}}\}.
\] (18)

Mean multiplicities \( \langle N_{abc} \rangle = r_{abc} \langle N^{(3)} \rangle \) are straightforwardly connected with the third order moments of the identified particle multiplicity distributions. For example,

\[
\langle N_{\pi\pi\pi} \rangle = \frac{\langle N_{\pi}(N_{\pi} - 1)(N_{\pi} - 2) \rangle}{6} = \left[ \frac{\langle N_{\pi}^3 \rangle}{3!} - 3 \langle N_{\pi}^2 \rangle + 2 \langle N_{\pi} \rangle \right],
\] (19)

\[
\langle N_{\pi\pi K} \rangle = \frac{\langle N_{\pi}(N_{\pi} - 1)N_K \rangle}{2} = \frac{1}{2} \left[ \langle N_{\pi}^2 N_K \rangle - \langle N_{\pi} N_K \rangle \right].
\] (20)

In this way the mean multiplicity of the identified three-particle set, \( \langle N_{abc} \rangle \), is obtained by a linear combination of third, second, and first moments of the identified particle multiplicity distributions. Similarly, third moments of the multiplicity distribution can be derived from a linear combination of mean multiplicities of single particles, particle pairs, and particle triplets.

The above procedures are straightforwardly extendable to \( k \)-particle sets and moments of order \( k \) with \( k > 3 \) for an arbitrarily large number of particle types.

**IV. SUMMARY**

The paper presents a new method, the Particle-Set Identification method, for reconstructing moments of multiplicity distribution of identified particles. A PSET represents a set of particles which is constructed from particles created in a collision. Mean multiplicities of particle sets of a given type are extracted from the measurements of the multi-dimensional distribution of a particle "mass" variable. This multi-dimensional distribution is used to calculate moments of the joint multiplicity distributions of identified particles.

First, the PSET Identification method is introduced for the simple case of two particle types and first and second moments. Then a sketch of the generalization of the method is presented for \( k \)-particle sets and moments of order \( k \) for any \( k \geq 3 \) for the case of an arbitrary number of particle types.
The PSET Identification method has a broader range of applicability than the Identity method introduced by us previously to solve the problem of incomplete particle identification. Particularly, it does not assume that measurements of particle "mass" for different particles are independent. The issue of introducing momentum dependent pdfs within the PSET identification method is left for future studies.
