This paper investigates the problem of full-order and reduced-order fault detection filter (FDF) design under unified linear matrix inequality (LMI) conditions for a class of continuous-time singular Markovian jump systems (CTSMJSs) with time-varying delays and polytopic uncertain transition rates. By constructing a new Lyapunov function, sufficient conditions are firstly provided for the singular model error augmented system such that the system is stochastically admissible with an $H_{\infty}$ performance level $\gamma$. And then, by applying a novel convex polyhedron technique to decoupled linear matrix inequalities, the full-order and reduced-order fault detection filter parameters can be obtained within a convex optimization frame. The reduced-order fault detection filter (FDF) can not only meet the fault detection accuracy requirements of complex systems but also improve the fault detection efficiency. Finally, a DC motor and an illustrative simulation example are given to verify the feasibility and effectiveness of the proposed algorithms.

1. Introduction

Markovian jump systems (MJSs) are usually defined as a family of complex random jumping parameter systems [1–4]. The past few decades have witnessed the prosperous research on MJSs because it can simulate the structure and parameter changes of real dynamic systems, such as biological economics systems, network control systems, power electronic systems, and mechanical engineering systems [5–9]. It is known that singular systems are completely different from ordinary systems, and when dealing with the stability of singular systems, we need to consider its regularity, the unique impulse-free solution, and admissibility, which are not considered in ordinary systems [10–17]. However, the singular systems have attracted much attention, and many studied results about singular systems have been reported because of their extensively practical applications, such as the filtering problem investigated in [10, 11], $H_{\infty}$ control problem studied in [12], stabilization problem addressed in [13], dissipative control problem investigated in [14], dynamic output feedback control problem considered in [15], and sliding mode control presented in [16].

It is worth mentioning that when the structure or parameters of the singular dynamic hybrid system change, the singular Markovian jump systems (SMJSs) can effectively simulate this phenomenon by using the Markov chain transformation, and many fruitful about SMJSs have been shown in recent years [17–19]. The transition rates (TRs) are the concrete expression of Markov chains, which can express the random transition state of the actual dynamic systems [20–22]. As the soul of SMJSs, TRs are generally considered to be completely known, partly unknown, and completely unknown in most studies [23–25]. It is worth noticing that the TRs with the polytopic uncertain cases are often encountered in practical applications, when the switching mode of the system is uncertain. Due to limitation of measurement conditions
under a harsh environment, component failures, and random abrupt changes of system structures, the system parameters changed randomly such that the RTs may be polytopic uncertain systems [26–28], for example, network control systems, VTOL (vertical take-off and landing machine) systems, and power systems. However, the fault detection filter of polytopic uncertain SMJSs has not been studied so far, which is the first motivation of our study.

In practice, however, the components or instrument are not always normal, and faults are unavoidable under practical conditions. More generally, the faults are often encountered in various forms. In order to improve the safety performance of the control systems, when the systems fail, we need to quickly detect the faults and avoid accidents. In order to pursue higher security and reliability, many scholars have studied the fault detection problems of Markovian jump systems [29–31]. These scholars only studied the fault detection problems of the ordinary Markovian jump systems. Since the singular Markovian jump systems are more complex than the ordinary Markovian jump systems, the stability, regularity, and nonimpulsiveness need to be considered [32–35]; especially for polytopic uncertain continuous-time singular Markovian jump systems, few scholars only studied the fault detection problems of the ordinary Markovian jump systems are more complex than the ordinary Markovian jump systems. Since the singular Markovian jump systems are more complex than the ordinary Markovian jump systems, the stability, regularity, and nonimpulsiveness need to be considered [32–35]; especially for polytopic uncertain continuous-time singular Markovian jump systems, few scholars only studied the fault detection problems of the ordinary Markovian jump systems. Since the singular Markovian jump systems are more complex than the ordinary Markovian jump systems, the stability, regularity, and nonimpulsiveness need to be considered [32–35]; especially for polytopic uncertain continuous-time singular Markovian jump systems, few scholars only studied the fault detection problems of the ordinary Markovian jump systems.

Additionally, it has been shown that time-varying delays are universal in real applications because of the signal transmission in communication, and it can lead to systems performance degradation and instability [34–38]. Inevitably, time delays also exist in SMJSs, and it is necessary to investigate the SMJSs with time-varying delays. As a hot topic, many fruits involving time-varying delays of SMJSs fault detection have been addressed [33–35]. It is worth mentioning that the fault detection of polytopic uncertain CTSMJSs with time-varying delays, which contains completely known, partly unknown, and completely unknown TRs, has not been studied. The polytopic uncertain SMJSs with time-varying delays can summarize actual systems more comprehensively, which is the other main motivation of this paper.

From what has been discussed above, in this paper, we will tackle the stochastic admissibility problem for polytopic uncertain CTSMJSs with time-varying delays via constructing a novel Lyapunov function. Then, based on a convex polyhedron technique to decoupled linear matrix inequalities, the full-order and reduced-order fault detection filters can be obtained. In particular, full-order and reduced-order FDF parameters can be computed in a convex optimization frame. On the premise of satisfying the requirement of fault detection accuracy, the proposed reduced-order FDF can effectively reduce the data storage and is less sensitive to external disturbance. The effectiveness of the derived results has been demonstrated by two illustrative examples.

The main contributions and novelties of this paper are summarized as follows. (I) The full-order and reduced-order FDFs for polytopic uncertain CTSMJSs with time-varying delays are proposed and designed for the first time. (II) The innovation reduced-order FDF design method of polytopic uncertain CTSMJSs with time-varying delays is proposed, which satisfies the stochastically admissible sufficient conditions and the $H_{\infty}$ performance standard $\gamma_{\min}$ for the first time. (III) By applying a novel decoupling technique, it has shown the full-order and reduced-order FDFs designed under a unified framework. Therefore, we can get the parameters of the full-order and reduced-order FDFs by adjusting the dimension of the decoupling matrix parameters, which can effectively improve the full-order and reduced-order FDF design scheme. (IV) In this paper, the proposed method not only can calculate parameters of full-order and reduced-order FDFs as the state TRM is polytopically uncertain but also can obtain the parameters of full-order and reduced-order FDFs when state TRM is completely under known, partly unknown, and completely unknown circumstances, and their performances are compared on conservative by simulation analysis.

Notations. The notations presented here are standard. $E[\cdot]$ stands for the mathematical expectation. sym($K$) stands for $K + K^T$. $P^*$ represents the $n$-dimensional identity matrix, and $0$ represents the zero matrix. $R$ is the set of real number, $R^n$ denotes the $n$-dimensional Euclidean space, and $R^{m \times n}$ is the set of $m \times n$ real matrix. About real symmetric matrix $P$, $P > 0$ means that $P$ is the real symmetric positive (semipositive) and * represents the symmetric term that has been ellipsis. $\|\cdot\|$ denotes the Euclidean norm for vectors. $l_2[0, \infty)$ is the space of square summable infinite sequence, and for $w = \{w(t)\} \in l_2[0, \infty)$, its norm is given by $\|w\|_2 = \sqrt{\int_0^\infty \|w(t)\|^2 dt}$.

2. Problem Formulation

In this section, we consider a class of CTSMJSs with time-varying delays on a complete probability space, which is described as follows:

\[
\begin{align*}
E x(t) &= A(r(t))x(t) + A_d(r(t))x(t - d(t)) + B(r(t))u(t) + E(r(t))w(t) + F(r(t))f(t), \\
y(t) &= C(r(t))x(t) + C_d(r(t)x(t - d(t)) + D(r(t))w(t) + H(r(t))f(t),
\end{align*}
\]

(1)

where $u(t) \in R^{n_u}$ represents the known input; $x(t) \in R^{n_x}$ stands for the plant state; $w(t) \in R^{n_w}$ is the exogenous disturbance signal; and $f(t) \in R^{n_f}$ is the fault signal to be detected. $E \in R^{n \times n}$ with rank($E$) = $r \leq n_x$; $u(t)$, $w(t)$, and $f(t)$, respectively, belong to $l_2[0, \infty)$. In addition, $d(t)$ denotes the time-varying delay and satisfying $0 \leq d_1 < d(t) < d_2 < \infty$, $d(t) \leq \bar{u} < \infty$, for all $t \geq 0$, where $d_1$, $d_2$, and $u$ are scalars, $\{d_1, d_2\} \in R_+$ represents the lower and upper delay bounds, respectively. $\{r(t), t \geq 0\}$ is a right-continuous Markov process, which takes values in a finite state-space set $S = \{1, 2, \ldots, N\}$ with the mode transition rate matrix (TRM) $\Pi = \{\lambda_{ij}\}_{N \times N}$, given by

\[
P_r([r(t) + \Delta]) = \begin{cases} 
\lambda_{ij} + 0(\Delta), & i \neq j, \\
1 + \lambda_{ii} + 0(\Delta), & i = j,
\end{cases}
\]

(2)

where $\Delta > 0$, $\lim_{\Delta \rightarrow 0} (0(\Delta)/\Delta) = 0$, and $\lambda_{ij} \geq 0$ is the transition rate from mode $i$ at time $t$ to mode $j$ at time $t + \Delta$ for $i \neq j$. 

\[
\begin{align*}
\lambda_{ij} &\geq 0, \\
\sum_{i=1}^{N} \lambda_{ij} &\leq 0.
\end{align*}
\]
For convenience, let \( r(t) = i \), such that real known constant system matrices \([A(r(t)), A_i(r(t)), B(r(t)), C(r(t)), C_d(r(t)), D(r(t)), E(r(t)), F(r(t)), H_i(r(t))]\) can be written as \([\bar{A}_i, \bar{A}_k, \bar{B}_i, \bar{C}_i, \bar{C}_d, \bar{D}_i, \bar{E}, \bar{F}, \bar{H}_i]\). The TRMs of the Markovian jump process are considered to be partly accessible and polytopic uncertain; that is, the TRM \( \Lambda = [\lambda_{ij}]_{n \times n} \) is hypothesized to belong to a known polytope \( P_\Lambda \) with vertices \( \Lambda_i \):

\[
P_\Lambda = \left\{ \Lambda = \sum_{i=1}^{M} a_i \Lambda_i; a_i \geq 0, \sum_{i=1}^{M} a_i = 1 \right\},
\]

where \( \Lambda_i = [\lambda_{ij}]_{n \times n}, i \in I, S = 1, 2, \ldots, M \) are known TRMs containing known, unknown, and polytopic uncertain elements still. For instance, the TRM of system (1) with three operation modes may be expressed as

\[
\begin{bmatrix}
\lambda_{11} & \cdots & \lambda_{1n} \\
\lambda_{21} & \cdots & \lambda_{2n} \\
\lambda_{n1} & \cdots & \lambda_{nn}
\end{bmatrix}
\]

where unknown and polytopic uncertain TRs are tagged with hat \( \lambda^{**} \) and \( \lambda^{*} \), respectively, and the others are known as TRs. For notational clarity, we describe \( S = S_k^{(i)} \cup S_{uk}^{(i)} \cup S_{uc}^{(i)} \) as follows:

\[
S_k^{(i)} = \{ j: \lambda_{ij} \text{ is known} \},
S_{uk}^{(i)} = \{ j: \lambda_{ij} \text{ is unknown} \},
S_{uc}^{(i)} = \{ j: \lambda_{ij} \text{ is uncertain} \}.
\]

Also, we can denote

\[
\lambda^{(0)}_{uk} = \sum_{j \in S_{uk}^{(i)}} \lambda_{ij} = 1 - \sum_{j \in S_k^{(i)}} \lambda_{ij} - \sum_{j \in S_{uc}^{(i)}} \lambda_{ij}.
\]

**Remark 1.** We define \( \lambda_k^{(i)} = \sum_{j \in S_k^{(i)}} \lambda_{ij} \) and \( \lambda^{(0)}_{uc} = \sum_{j \in S_{uc}^{(i)}} \lambda_{ij} \). For achievement, the numerical solvability of the performance analysis, when \( \Lambda \) is unknown, by providing a lower bound element \( \lambda^{(i)}_{k} \leq (\lambda^{(i)}_{k} + \lambda^{(0)}_{uc}) \) is provided to restrict the diagonal element of TRM. In this paper, our primary mission is to design FDF for original system (1), and the FDF is considered as follows:

\[
\begin{cases}
\dot{x}_f(t) = A_{fi}x_f(t) + B_{fi}y(t), \\
\dot{r}_f(t) = C_{fi}x_f(t) + D_{fi}y(t),
\end{cases}
\]

where \( r_f(t) \in R^{n_f} \) is the residual, \( x_f(t) \in R^{n_f} (1 \leq n_f \leq n_x) \) is the state estimation of filter, and the full-order and reduced-order FDF parameter matrices \( A_{fi} \in R^{n_f \times n_f}, B_{fi} \in R^{n_f \times n_y}, C_{fi} \in R^{n_x \times n_f}, \) and \( D_{fi} \in R^{n_y \times n_f} \) can be computed, respectively, when \( 1 \leq n_f = n_x \) or \( 1 \leq n_f < n_x \).

In this paper, we introduce \( \tilde{f}(s) = W_f(s)f(s) \) to improve the performance of the fault detection system by limiting the frequency interval, where \( f(s) \) represents the weighting fault signal and \( W_f(s) \) represents the stable weighting matrix function. \( f(s) \) and \( \tilde{f}(s) \) denote Laplace transforms of \( f(t) \) and \( \tilde{f}(t) \), separately. The minimal state-space realization of \( \tilde{f}(s) = W_f(s)f(s) \) is supposed to be

\[
\begin{cases}
\dot{x}_f(t) = A_{wfi}x_f(t) + B_{wfi}f(t), \\
\tilde{f}(t) = C_{wfi}x_f(t) + D_{wfi}f(t),
\end{cases}
\]

where \( x_f(t) \in R^{n_x} \) is the state vector and \( A_{wfi}, B_{wfi}, C_{wfi}, \) and \( D_{wfi} \) are arbitrary constant matrices. Notice that \( e(t) = r_f(t) - \tilde{f}(t) \) denotes the weighted fault estimation error. Considering expressions (1), (7), and (8), the following singular model error augmented system can be obtained:

\[
\begin{cases}
\dot{\bar{E}}(t) = \bar{A}_i\bar{x}(t) + \bar{A}_{di}\Phi\bar{x}(t - d(t)) + \bar{B}\Psi(t), \\
e(t) = \bar{C}_i\bar{x}(t) + \bar{C}_{di}\Phi\bar{x}(t - d(t)) + \bar{D}_i\Psi(t),
\end{cases}
\]

where \( \Psi(t) = [u^T(t) \ w^T(t) \ f^T(t)]^T, \bar{x}(t) = [x^T(t) \ x_f^T(t) \ \tilde{x}_f^T(t)]^T \) and

\[
\bar{E} = \begin{bmatrix} E & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & I \end{bmatrix},
\]

\[
\begin{bmatrix} A_{di} \ 0 \ 0 \\ 0 & B_{wfi} \ 0 \end{bmatrix},
\]

\[
\begin{bmatrix} B_i & E_i & F_i \\ 0 & B_{wfi} & \bar{D}_i \\ 0 & 0 & B_{wfi} \end{bmatrix},
\]

\[
\begin{bmatrix} D_{fi} & C_{fi} & C_{fi} & -C_{wfi} \end{bmatrix},
\]

\[
\begin{bmatrix} I & 0 \ 0 \ 0 \end{bmatrix}.
\]

**Remark 2.** \( u(t) \) is the known input of the system, which is combined with the disturbance \( w(t) \) and fault \( f(t) \) to form the input of the singular model error augmented system (9) because when \( u(t) = 0 \), the \( H_{\infty} \) performance \( \gamma \) and conservativeness of the system will decrease, and it can be regarded as the negative input of the system.

**Remark 3.** In fact, the singular model error augmented system (9) has the characteristics of singular system. In order to better study the stability of system (9), we must ensure the solution is reasonable for the singular model error augmented system (9) when the input \( \Psi(t) = 0 \). Therefore, we give the following Assumption 1 and Lemma 1.

**Assumption 1.** For every \( i \in I \), there exists a pair of nonsingular matrices \( M, N \in R^{[n_x \times n_f \times n_u] \times [n_x \times n_f \times n_u]} \) such that
\[ M \bar{E} N = \begin{bmatrix} I_{(r,n_1,n_2)} & 0_{(r,n_1,n_2)\times(n_1-r)} \\ 0_{(n_1-r)\times(r,n_1,n_2)} & 0_{(n_1-r)\times(n_1-r)} \end{bmatrix}. \]

11

\[ M \bar{A}_i N = \begin{bmatrix} \bar{A}_{i1} & \bar{A}_{i2} \\ \bar{A}_{i3} & \bar{A}_{i4} \end{bmatrix}. \]

\[ M \bar{A}_i d_t N = \begin{bmatrix} \bar{A}_{id1} & \bar{A}_{id2} \\ \bar{A}_{id3} & \bar{A}_{id4} \end{bmatrix}. \]

Lemma 1. Under Assumption 1, the unforced singular model error augmented system (9) has a unique (right-continuous) solution.

Proof. Let \( \zeta(t) = N^{-1}\tilde{x}(t) = \begin{bmatrix} \zeta_1^T(t) \ z_1^T(t) \end{bmatrix} \), \( \zeta_1(t) \in R^{(r,n_1,n_2)}, \) and \( \zeta_2(t) \in R^{(n_1-r)}, \) then unforced subsystem (9) can be written as the following form:

\[
\begin{aligned}
\dot{\zeta}_1(t) &= \bar{A}_{11}\zeta_1(t) + \bar{A}_{12}\zeta_2(t) + \bar{A}_{d1}\zeta_1(t - d(t)) \\
&+ \bar{A}_{d1}\zeta_2(t - d(t)), \\
\dot{\zeta}_2(t) &= \bar{A}_{22}\zeta_2(t) + \bar{A}_{23}\zeta_2(t) + \bar{A}_{d3}\zeta_1(t - d(t)) \\
&+ \bar{A}_{d3}\zeta_2(t - d(t)),
\end{aligned}
\]

or

\[
\begin{aligned}
\dot{\zeta}_1(t) &= \bar{A}_{11}\zeta_1(t) + \bar{A}_{12}\zeta_2(t) - \bar{A}_{d1}\zeta_1(t - d(t)) \\
&+ \bar{A}_{d1}\zeta_2(t - d(t)), \\
\dot{\zeta}_2(t) &= \bar{A}_{22}\zeta_2(t) + \bar{A}_{23}\zeta_2(t) + \bar{A}_{d3}\zeta_1(t - d(t)) \\
&+ \bar{A}_{d3}\zeta_2(t - d(t)),
\end{aligned}
\]

Therefore, according to [35–38], the unforced input system (9) has a unique impulse-free solution for all \( t \geq 0 \) when Assumption 1 holds. Before proceeding to the next step, we introduce the following important definitions to drive our main results.

Definition 1 (see [11]). The model error augmented system (9) is said to be as follows:

(1) Regular, if any \( i \in I \) and \( \Psi(t) = 0, \) det \( (s\bar{E} - \bar{A}_i) \neq 0. \)

(2) Impulse-free, if any \( i \in I \) and \( \Psi(t) = 0, \)

\[ \deg(\det(s\bar{E} - \bar{A}_i)) = \text{rank}(\bar{E}). \]

(3) Stochastically stable, if for any initial state \( \tilde{x}(0) \in R^{n_1}, \) \( r(0) \in I, \) there exists a scalar \( M(\tilde{x}_0, r_0) > 0, \) such that the following inequality holds:

\[
E \int_0^\infty \|\tilde{x}(t)\|^2 \leq M(\tilde{x}_0, r_0).
\]

(4) Stochastically admissible, if system (9) is regular, impulse-free, and stochastically stable.

Definition 2 (see [11]). Given a scalar \( \gamma > 0 \) and under the condition \( \Psi(t) \in I_1[0,\infty), \) singular model error augmented system (9) is said to be stochastically admissible and has an \( H_\infty \) noise attenuation performance index \( \gamma, \) if the following conditions can be satisfied.

(1) When \( \Psi(t) = 0, t \geq 0, \) and condition (3) of Definition 1 is satisfied, system (9) is stochastically stable.

(2) When \( \Psi(t) \neq 0, t \geq 0, \) under zero initial conditions, the following inequality holds:

\[
E \int_0^\infty e^T(t)\phi(t)dt < \gamma^2 E \int_0^\infty \Psi^T(t)\Psi(t)dt.
\]

We assume that polytopic uncertain CTSMJSs with time-varying delays (1) is stochastic admissible. The main purpose of this paper is to obtain the parameters of the fault detection filtering system (7) under the premise that the model error augmented system (9) is stochastically admissible with the \( H_\infty \) performance level \( \gamma. \) To improve fault detection performance, we define the following residual estimation function \( \tilde{f}(t) \) and threshold \( J_{th}: \)

\[
\tilde{f}(t) = \begin{cases} f(t) & \text{if } t < k_0 \\ \tilde{f}(k_0) & \text{if } t \geq k_0 \end{cases},
\]

\[
J_{th} = \sup_{0 \leq w_{el_1} \leq \delta_{el_2} \leq 0} E[J(\tilde{f}(t))],
\]

where \( k_0 \) represents the moment of initial evaluation and \( L \) represents the evaluation time step. If fault \( f(t) \) has occurred, it can be detected by the following logical relationships \( J(\tilde{f}(t)) > J_{th} \rightarrow \text{fault happened} \rightarrow \text{alarm} \) and \( J(\tilde{f}(t)) \leq J_{th} \rightarrow \text{fault free}. \)

In order to facilitate subsequent research, we will give the following Jensen inequality.

Lemma 2 (see [39]). For any positive-definite symmetric matrix \( M \in R^{n \times n}, \) scalar \( b > a, \) and vector function \( v: [a,b] \rightarrow R^n, \) such that the following inequality holds:

\[
\left( \int_a^b v(s)ds \right)^T M \left( \int_a^b v(s)ds \right) \leq (b-a) \int_a^b v^T(s)Mv(s)ds.
\]

3. Performance Analysis of FDFS

In this section, the \( H_\infty \) performance analysis level is firstly derived for system (9). Then, present the FDF design method for CTSMJSs with completely known TRs and time-varying delays.

Theorem 1. Under Assumption 1, given scalars \( d_1, \) \( d_2 \left( 0 \leq d_1 \leq d_2 \right), \) \( u \geq 0, \) for any time-varying delays \( d(t), \) the continuous-time singular error augmented system (9) is stochastically admissible with an \( H_\infty \) performance level \( \gamma. \) If there exists any symmetric positive-definite matrices \( P_i \in R^{(n_1+n_2+r_n)\times(n_1+n_2+r_n)} \), \( Z_i, Z_{i2}, R_1, R_2, Q_{i1}, Q_{i2}, Q_{i3} \in R^{n_1+r_n}, \) appropriate dimensions matrices \( \bar{N}_i, S \in R^{(n_1+n_2+r_n)\times(n_1-r)}, \) and satisfying \( \bar{E}^T S = 0, \) such that the following LMIs hold for any \( i, j \in I: \)

(1) When \( \Psi(t) = 0, t \geq 0, \) and condition (3) of Definition 1 is satisfied, system (9) is stochastically stable.

(2) When \( \Psi(t) \neq 0, t \geq 0, \) under zero initial conditions, the following inequality holds:

\[
E \int_0^\infty e^T(t)e(t)dt < \gamma^2 E \int_0^\infty \Psi^T(t)\Psi(t)dt.
\]
\[ \begin{align*}
&\sum_{j=1}^{N} \lambda_{ij}(Q_{ij} + Q_{3j}) \leq Z_2, \\
&\sum_{j=1}^{N} \lambda_{ij}Q_{2j} \leq Z_1, \\
&\sum_{j=1}^{N} \lambda_{ij}Q_{3j} \leq Z_2,
\end{align*} \]

(17)

\[ \Omega_i = \begin{bmatrix}
\Omega_{11} & \Omega_{12} & \tilde{E}^T \Phi^T R_1 \Phi \tilde{E} & 0 & \Omega_{15} & \Omega_{16} & \bar{C}_i^T \\
\ast & \Omega_{22} & \tilde{E}^T \Phi^T R_2 \Phi \tilde{E} & \tilde{E}^T \Phi^T R_2 \Phi \tilde{E} & 0 & \Omega_{26} & \Phi^T C_{d1}^T \\
\ast & \ast & \Omega_{33} & 0 & 0 & 0 & 0 \\
\ast & \ast & \ast & \Omega_{44} & 0 & 0 & 0 \\
\ast & \ast & \ast & \ast & -\gamma^2 I & \Omega_{56} & \tilde{D}_i^T \\
\ast & \ast & \ast & \ast & \ast & \ast & -I
\end{bmatrix} < 0, \]

\[ \Omega_{11} = \sum_{j=1}^{N} \lambda_{ij} \tilde{E}^T P_j \tilde{E} + \text{sym}(\tilde{E}^T P_j \tilde{A}_j) + \text{sym}(\tilde{A}_j^T \tilde{S} \tilde{N}_j^T) + \Phi^T (Q_{ii} + Q_{2i} + Q_{3i} + d_i Z_1 + d_2 Z_2) \Phi - \tilde{E}^T \Phi^T R_1 \Phi \tilde{E}, \]

\[ \Omega_{12} = \tilde{E}^T P_j \tilde{A}_j \Phi + \tilde{N}_j \tilde{S} \tilde{A}_j \Phi, \]

\[ \Omega_{13} = \tilde{N}_j \tilde{S} \tilde{B}_j + \tilde{E}^T P_j \tilde{B}_j, \]

\[ \Omega_{16} = \tilde{A}_j^T \Phi^T (d_i^2 R_1 + d_{i2}^2 R_2) \Phi, \]

\[ \Omega_{22} = -(1 - u) \Phi^T Q_{11} \Phi - 2 \tilde{E}^T \Phi^T R_2 \Phi \tilde{E}, \]

\[ \Omega_{26} = \Phi^T \tilde{A}_j^T \Phi^T (d_i^2 R_1 + d_{i2}^2 R_2) \Phi, \]

\[ \Omega_{33} = -\Phi^T Q_{2i} \Phi - E^T \Phi^T (R_1 + R_2) \Phi E, \]

\[ \Omega_{44} = -\Phi^T Q_{3i} \Phi - E^T \Phi^T R_2 \Phi E, \]

\[ \Omega_{56} = \tilde{B}_j^T \Phi^T (d_i^2 R_1 + d_{i2}^2 R_2) \Phi, \]

\[ \Omega_{66} = -\Phi^T (d_i^2 R_1 + d_{i2}^2 R_2) \Phi. \]

(18)

**Proof.** Firstly, the regularity and impulse-free for system (9) are proved. From (18), we have

\[ \text{sym}(\tilde{E}^T P_j \tilde{A}_j) + \text{sym}(\tilde{A}_j^T \tilde{S} \tilde{N}_j^T) < 0, \]

(19)

Suppose that Assumption 1 is satisfied, \( \text{rank}(\tilde{E}) = r + n_f + n_w < n_c + n_f + n_w \) and nonsingular matrices \( M, N \in \mathbb{R}^{(n_c+n_f+n_w-r) \times (n_c+n_f+n_w)} \) such that

\[ M^{-T} P_j M^{-1} = \begin{bmatrix} P_{ii} & P_{i2} \\ P_{i3} & P_{ii} \end{bmatrix}, \]

\[ N^T \tilde{N}_j = \begin{bmatrix} \tilde{N}_{ii} \\ \tilde{N}_{i2} \end{bmatrix}, \]

\[ M^{-T} \tilde{S} = \begin{bmatrix} 0 \\ S \end{bmatrix}, \]

where \( S \in \mathbb{R}^{(n_c+n_f+n_w-r) \times (n_c+n_f+n_w-r)} \); premultiplying and postmultiplying (19) by \( N^T \) and \( N \), respectively, we get \( \tilde{A}_j^T \tilde{S} \tilde{N}_j^T + \tilde{N}_j \tilde{S} \tilde{A}_j^T \) or \( \tilde{A}_j^T \tilde{N}_j \tilde{S} \tilde{A}_j^T \), which is nonsingular according to Lemma 1 and (1) and (2) in Definition 1, the unforced singular model error augmented system (9) is regular and impulse-free. For the stochastic admissible and \( H_{\infty} \) property analysis of system (9), under the zero initial condition and suppose \( d(t) \) is differentiable, that is, \( \dot{\Psi}(t) = 0 \), let us define \( \bar{x}_i(s) = \bar{x}(t + s), s \in [d_1, d_2] \), and choose the following Lyapunov functional:

\[ V(\bar{x}(t), t) = \sum_{s=1}^{4} V_j(\bar{x}(t), t), \]

(21)

where
determined. Let $Q_l = Q_l I$, $l \in \{1, 2, 3\}$, $Z_1 = Z_1^2 > 0$, $Z_2 = Z_2^2 > 0$ will be determined. Let $\delta$ be the weak infinitesimal generator of random process $(\bar{x}(t), r(t))$, for each $r(t) = i, i \in S$, then the infinitesimal operator along the state trajectory of system (9) can be obtained:

\[
\delta V_1(\bar{x}(t), i, t) = \bar{x}^T(t)E^T P_i \bar{E} \bar{x}(t),
\]

\[
\delta V_2(\bar{x}(t), i, t) = \int_{t-d_1}^{t} \bar{x}^T(\alpha) \Phi^T Q_{i1} \Phi \bar{x}(\alpha) d\alpha + \int_{t-d_2}^{t} \bar{x}^T(\alpha) \Phi^T Q_{i2} \Phi \bar{x}(\alpha) d\alpha + \int_{t-d_1}^{t} \bar{x}^T(\alpha) \Phi^T Q_{i3} \Phi \bar{x}(\alpha) d\alpha,
\]

\[
\delta V_3(\bar{x}(t), i, t) = \int_{t-d_1}^{t} \bar{x}^T(\alpha) \Phi^T Z_1 \Phi \bar{x}(\alpha) d\alpha + \int_{t-d_2}^{t} \bar{x}^T(\alpha) \Phi^T Z_2 \Phi \bar{x}(\alpha) d\alpha,
\]

\[
\delta V_4(\bar{x}(t), i, t) = d_1 \int_{t-d_1}^{t} \bar{x}^T(\alpha) \Phi^T R \Phi \bar{x}(\alpha) d\alpha + d_2 \int_{t-d_2}^{t} \bar{x}^T(\alpha) \Phi^T R \Phi \bar{x}(\alpha) d\alpha + d_1 \int_{t-d_1}^{t} \bar{x}^T(\alpha) \Phi^T R \Phi \bar{x}(\alpha) d\alpha + d_2 \int_{t-d_2}^{t} \bar{x}^T(\alpha) \Phi^T R \Phi \bar{x}(\alpha) d\alpha,
\]

where parameter-dependent Lyapunov matrices $P_i = P_i^T$, $Q_l = Q_l^T > 0$, $l \in \{1, 2, 3\}$, $Z_1 = Z_1^2 > 0$, $Z_2 = Z_2^2 > 0$ will be determined. Let $\delta$ be the weak infinitesimal generator of random process $(\bar{x}(t), r(t))$, for each $r(t) = i, i \in S$, then the infinitesimal operator along the state trajectory of system (9) can be obtained:
According to Lemma 1, we can obtain

\[
-d_1 \int_{t-d_1}^t \tilde{x}(a) \Phi^T R_1 \Phi \tilde{E}(a) da \leq - \left( \int_{t-d_1}^t \Phi \tilde{E}(a) da \right)^T R_1 \left( \int_{t-d_1}^t \Phi \tilde{E}(a) da \right) \\
= - \left[ \tilde{x}(t) - \tilde{x}(t - d_1) \right]^T \tilde{E}^T \Phi^T R_1 \Phi \tilde{E} \tilde{x}(t) - \tilde{x}(t - d_1) - d_1 \int_{t-d_1}^{t-d_1} \tilde{x}(a)^T \Phi^T R_2 \Phi \tilde{E}(a) da \\
= -d_1 \int_{t-d_1}^{t-d_1} \tilde{x}(a)^T \Phi^T R_2 \Phi \tilde{E}(a) da - d_1 \int_{t-d_1}^{t-d_1} \tilde{x}(a)^T \Phi^T R_2 \Phi \tilde{E}(a) da \\
\leq - \frac{d_1}{d(t) - d_1} \left[ \int_{t-d_1}^{t-d_1} \Phi \tilde{E}(a) da \right]^T R_2 \left[ \int_{t-d_1}^{t-d_1} \Phi \tilde{E}(a) da \right] - \frac{d_1}{d(t) - d_1} \\
\cdot \left[ \int_{t-d_1}^{t-d_1} \Phi \tilde{E}(a) da \right]^T R_2 \left[ \int_{t-d_1}^{t-d_1} \Phi \tilde{E}(a) da \right].
\]

(24)

Next, let us estimate the upper bound of the two terms on the right side of the above inequality.

When \(0 < d_1 < d(t) < d_2\), there is

\[
d(t) - d_1 < d_2 - d_1 \implies \begin{cases} 
\frac{d_2 - d_1}{d(t) - d_1} > 1 & \iff - \frac{d_2 - d_1}{d(t) - d_1} < -1, \\
\frac{d_2 - d_1}{d_2 - d(t)} > 1 & \iff - \frac{d_2 - d_1}{d_2 - d(t)} < -1.
\end{cases}
\]

(25)

Therefore, the following can be obtained:

\[
\delta V_4(\tilde{x}(t), i, t) < \tilde{x}(t)^T \Phi^T \left( d_1^2 R_1 + d_1^2 R_2 \right) \Phi \tilde{E}(t) - \left( \int_{t-d_1}^{t} \Phi \tilde{E}(a) da \right)^T R_1 \left( \int_{t-d_1}^{t} \Phi \tilde{E}(a) da \right) \\
- \left( \int_{t-d(t)}^{t-d(t)} \Phi \tilde{E}(a) da \right)^T R_2 \left( \int_{t-d(t)}^{t-d(t)} \Phi \tilde{E}(a) da \right) - \left( \int_{t-d_1}^{t-d(t)} \Phi \tilde{E}(a) da \right)^T R_2 \left( \int_{t-d_1}^{t-d(t)} \Phi \tilde{E}(a) da \right) \\
= \tilde{x}(t)^T \Phi^T \left( d_1^2 R_1 + d_1^2 R_2 \right) \Phi \tilde{E}(t) - [\tilde{x}(t - d_1) - \tilde{x}(t - d(t))]^T \tilde{E}^T \Phi^T R_1 \Phi \tilde{E}(t) - \tilde{x}(t - d(t)) \\
- [\tilde{x}(t - d(t)) - \tilde{x}(t - d_1)]^T \tilde{E}^T \Phi^T R_2 \Phi \tilde{E}(t - d(t)) - \tilde{x}(t - d_1) \\
- [\tilde{x}(t - d(t)) - \tilde{x}(t - d_1)]^T \tilde{E}^T \Phi^T R_2 \Phi \tilde{E}(t - d(t)) - \tilde{x}(t - d_1) \\
= [\tilde{A}_x(t) + \tilde{A}_d \Phi \tilde{E}(t - d(t))]^T \Phi^T \left( d_1^2 R_1 + d_1^2 R_2 \right) \Phi \tilde{x}(t) + [\tilde{A}_x(t) + \tilde{A}_d \Phi \tilde{x}(t - d(t)))]^T \tilde{E}^T \Phi^T R_1 \Phi \tilde{E}(t) - \tilde{x}(t - d(t)) \\
- [\tilde{x}(t - d(t)) - \tilde{x}(t - d_1)]^T \tilde{E}^T \Phi^T R_2 \Phi \tilde{E}(t - d(t)) - \tilde{x}(t - d_1) \\
- [\tilde{x}(t - d(t)) - \tilde{x}(t - d_1)]^T \tilde{E}^T \Phi^T R_2 \Phi \tilde{E}(t - d(t)) - \tilde{x}(t - d_1) \\
- [\tilde{x}(t - d(t)) - \tilde{x}(t - d_1)]^T \tilde{E}^T \Phi^T R_2 \Phi \tilde{E}(t - d(t)) - \tilde{x}(t - d_1)].
\]

(26)
Noting that $\bar{E}^T S = 0$ and $\bar{E} \bar{N} = 0$, we have

$$\nabla V(\bar{x}(t), i, t) = \bar{x}^T(t) \bar{E}^T S \bar{N}^T \bar{x}(t) + \bar{x}^T(t) \bar{N} \bar{S}^T \bar{x}(t)$$

$$= [\bar{A}_i \bar{x}(t) + \bar{A}_d \bar{\Phi} \bar{x}(t - d(t))]^T \bar{S} \bar{N}^T \bar{x}(t) + \bar{x}^T(t) \bar{N} \bar{S}^T \bar{x}(t - d(t) + \bar{x}^T(t) \bar{N} \bar{S}^T \bar{x}(t - d(t)) ] = 0.$$  \hfill (27)

Add the weak infinitesimal operators to get the following equation:

$$\delta V(\bar{x}(t), i, t)$$

$$= \delta V_1(\bar{x}(t), i, t) + \delta V_2(\bar{x}(t), i, t) + \delta V_3(\bar{x}(t), i, t) + \delta V_4(\bar{x}(t), i, t) + \nabla V(\bar{x}(t), i, t)$$

$$\leq \bar{x}^T(t) \left( \sum_{j=1}^N \lambda_{ij} \bar{E}^T P_j E \right) \bar{x}(t) + \bar{x}^T(t) \bar{E}^T P_1 \left[ \bar{A}_i \bar{x}(t) + \bar{A}_d \bar{\Phi} \bar{x}(t - d(t)) \right] + \left[ \bar{A}_i \bar{x}(t) + \bar{A}_d \bar{\Phi} \bar{x}(t - d(t)) \right] \bar{E}^T \bar{x}(t)$$

$$+ \bar{x}^T(t) \bar{E}^T (Q_{1i} + Q_{2i} + Q_{3i}) \bar{\Phi} \bar{x}(t) - (1 - u) \bar{x}^T(t - d(t)) \bar{E}^T Q_{1i} \bar{\Phi} \bar{x}(t - d(t)) - \bar{x}^T(t - d_i) \bar{E}^T \bar{\Phi} \bar{x}(t - d_i)$$

$$- \bar{x}^T(t - d_i) \bar{E}^T Q_{2i} \bar{\Phi} \bar{x}(t - d_i) + \int_{t - d_i}^t \bar{x}^T(\alpha) d \bar{x}(\alpha) \left[ \sum_{j=1}^N \lambda_{ij} Q_{1j} \right] \bar{\Phi} \bar{x}(\alpha) d \alpha + \int_{t - d_i}^t \bar{x}^T(\alpha) d \bar{x}(\alpha) \left[ \sum_{j=1}^N \lambda_{ij} Q_{2j} \right] \bar{\Phi} \bar{x}(\alpha) d \alpha$$

$$+ \int_{t - d_i}^t \bar{x}^T(\alpha) d \bar{x}(\alpha) \left[ \sum_{j=1}^N \lambda_{ij} Q_{3j} \right] \bar{\Phi} \bar{x}(\alpha) d \alpha + \bar{x}^T(t) \bar{E}^T \left[ d_i Z_i + d_i Z_i \right] \bar{\Phi} \bar{x}(t)$$

$$\cdot \left[ \bar{A}_i \bar{x}(t) + \bar{A}_d \bar{\Phi} \bar{x}(t - d(t)) \right] - \left[ \bar{x}(t) - \bar{x}(t - d_i) \right] \bar{E}^T \bar{\Phi} \bar{E} \bar{R}_i \bar{E} \bar{x}(t - d_i)$$

$$- \left[ \bar{x}(t - d_i) - \bar{x}(t - d(t)) \right] \bar{E}^T \bar{\Phi} \bar{E} \bar{R}_i \bar{E} \bar{x}(t - d(t))$$

$$+ \left[ \bar{x}(t - d(t)) - \bar{x}(t - d_i) \right] \bar{E}^T \bar{\Phi} \bar{E} \bar{R}_i \bar{E} \bar{x}(t - d(t)) + \bar{x}^T(t) \bar{E}^T S \bar{N}^T \bar{x}(t) + \bar{x}^T(t) \bar{N} \bar{S}^T \bar{x}(t)$$

$$\xi_1(t) \Omega_{11} \xi_1(t).$$  \hfill (28)

where

$$\xi_1(t) = \left[ \bar{x}^T(t) \quad \bar{x}^T(k - d(t)) \quad \bar{x}^T(t - d_i) \right]^T,$$

$$\Omega_{ii} = \begin{bmatrix} \Omega_{11} & \Omega_{12} & E^T \Phi^T R_1 \Phi \bar{E} & 0 \\ * & \Omega_{22} & E^T \Phi^T R_2 \Phi \bar{E} & 0 \\ * & * & \Omega_{33} & 0 \\ * & * & * & \Omega_{44} \end{bmatrix},$$

$$\Omega_{11} = \sum_{j=1}^N \lambda_{ij} E^T P_j \bar{E} + \text{sym} \left( \bar{A}_i^T S \bar{N}^T \right) + \Phi^T \left( Q_{1i} + Q_{2i} + Q_{3i} + d_i Z_i + d_i Z_i \right) \Phi$$

$$- \bar{E}^T \Phi^T R_1 \Phi \bar{E} + \bar{A}_i^T \Phi^T \left( d_i^2 R_i + d_i^2 R_i \right) \Phi \bar{A}_i,$$

$$\Omega_{12} = \bar{E}^T P_1 \bar{A}_d \Phi + \bar{N} \bar{S}^T \bar{A}_d \Phi + \bar{A}_i^T \Phi^T \left( d_i^2 R_i + d_i^2 R_i \right) \Phi \bar{A}_d \Phi,$$

$$\Omega_{22} = -(1 - u) \Phi^T Q_{1i} \Phi - 2 \bar{E}^T \Phi^T R_2 \Phi \bar{E} + \Phi^T \bar{A}_d^T \Phi^T \left( d_i^2 R_i + d_i^2 R_i \right) \Phi \bar{A}_d \Phi,$$

$$\Omega_{33} = -\Phi^T Q_{2i} \Phi - \bar{E}^T \Phi^T \left( R_i + R_i \right) \Phi \bar{E},$$

$$\Omega_{44} = -\Phi^T Q_{3i} \Phi - \bar{E}^T \Phi^T R_2 \Phi \bar{E}. \hfill (29)$$
If $\delta V(\bar{x}(t), i, t) = \xi^T_1(t)\Omega_1i_1\xi_1(t) < 0$ is true, system (9) is stochastically stable. Next, we derive the conditions for $\delta V(\bar{x}(t), i, t) < 0$ to be true. Let the minimum eigenvalue of matrix $-\Psi_i$ be $\lambda_{\text{min}}(-\Psi_i)$. According to equation (28), the following equation can be obtained:

$$
\delta V(\bar{x}(t), i, t) < -\lambda_{\text{min}}(-\Psi_i)\bar{x}^T(t)\bar{x}(t).
$$

(30)

According to Dynkin formula, we can get

$$
E[V(\bar{x}(t), r(t))] - V(\bar{x}_0, r_0) = E\left[\int_0^t \delta V(\bar{x}(s), r(s), s)ds\right] 
\leq -\lambda_{\text{min}}(-\Psi_i)E\left[\int_0^t \bar{x}^T(s)\bar{x}(s)ds \bigg| \bar{x}_0, r_0\right],
$$

(31)

from $V(x(t), r(t), t) \geq 0$; when $\delta V(\bar{x}(t), r(t), t) < 0$, the following formula is true:

$$
E\left[\int_0^t \bar{x}^T(s)\bar{x}(s)ds \bigg| \bar{x}_0, r_0\right] \leq \frac{V(\bar{x}_0, r_0)}{\lambda_{\text{min}}(-\Psi_i)} = M(\bar{x}_0, r_0).
$$

(32)

When the upper limit of the integration tends to infinity, it can be deduced:

$$
E\left[\int_0^\infty \bar{x}^T(s)\bar{x}(s)ds \bigg| \bar{x}_0, r_0\right] \leq M(\bar{x}_0, r_0).
$$

(33)

According to (2) in Definition 2, the following formula can be obtained:

$$
J(T) 
\leq E\left[\int_0^T [e^T(t)e(t) - k^2\Psi(t)k(t) + \delta V(\bar{x}(t), r(t), t)]dt\right] 
\leq E\left[\int_0^T [\delta V(\bar{x}(t), r(t), t)]dt\right].
$$

(35)

Applying the Schur theorem to formula (35), formula (18) can be obtained. Theorem 1 is proved. $\Box$

**Theorem 2.** Considering singular model error augmented system (9) with polytopic uncertain transition rates and time-varying delays is stochastically admissible with an $H_{\infty}$ performance index $\gamma$. If there exist positive-definite symmetric matrices $P_i \in R^{(n_x + n_f + n_u) \times (n_x + n_f + n_u)}$, $Z_i, Z_1, Z_2, R_1, R_2, Q_1, Q_2, Q_3, Q_4 \in R^{n_x \times n_x}$, any appropriate dimensions matrices $\bar{S}, \bar{N}, i \in R^{(n_x + n_f + n_u) \times (n_x - r)}$, and satisfying $E\bar{S}^T = 0$, such that the following LMIs hold for any $\forall i, j \in I$:
\( \delta_{1k}^{(i)} = \sum_{j \in S_k^{(i)}} \lambda_{ij} Q_{1j} + \sum_{j \in S_{uc}^{(i)}} \lambda_{ij}^{(o)} Q_{1j}, \)
\[ \delta_{2k}^{(i)} = \sum_{j \in S_k^{(i)}} \lambda_{ij} Q_{2j} + \sum_{j \in S_{uc}^{(i)}} \lambda_{ij}^{(o)} Q_{2j}, \]  
\[ \delta_{3k}^{(i)} = \sum_{j \in S_k^{(i)}} \lambda_{ij} Q_{3j} + \sum_{j \in S_{uc}^{(i)}} \lambda_{ij}^{(o)} Q_{3j}, \]

If \( i \in S_k^{(i)} \cup S_{uc}^{(i)}, j \in S_{nk}^{(i)} \),
\[ \begin{cases} 
\delta_{1k}^{(i)} + \delta_{3k}^{(i)} - (\lambda_k^{(i)} + \lambda_{uc}^{(i)}) (Q_{1j} + Q_{3j}) < Z_2, \\
\delta_{2k}^{(i)} - (\lambda_k^{(i)} + \lambda_{uc}^{(i)}) Q_{2j} < Z_1, \\
\delta_{3k}^{(i)} - (\lambda_k^{(i)} + \lambda_{uc}^{(i)}) Q_{3j} < Z_2.
\end{cases} \]  

When \( i \in S_k^{(i)} \cup S_{uc}^{(i)} \), it is indicated that diagonal elements \( \lambda_{ij} \) are known or uncertain, then \( \lambda_k^{(i)} + \lambda_{uc}^{(i)} \leq 0 \). Since \( \lambda_k^{(i)} + \lambda_{uc}^{(i)} = 0 \), all the elements in the \( i \text{th} \) row of the vertex \( \Lambda_{ik}, i = 1, 2, \ldots M \) are known, we only need to consider the case \( \lambda_k^{(i)} + \lambda_{uc}^{(i)} < 0 \) and rewrite the term \( \sum_{j=1}^{N} \lambda_{ij} P_j \) in formula (18) as

\( \sum_{j \in S_k^{(i)}} \lambda_{ij} P_j + \sum_{j \in S_{uc}^{(i)}} \lambda_{ij}^{(o)} P_j + \sum_{j \in S_{nk}^{(i)}} \left( \sum_{l=1}^{M} \alpha_{l} \lambda_{ij}^{(l)} \right) P_j \)
\[ = \sum_{j \in S_k^{(i)}} \lambda_{ij} P_j - \lambda_{k}^{(i)} - \lambda_{uc}^{(i)} \sum_{j \in S_{uc}^{(i)}} \lambda_{ij}^{(o)} P_j + \sum_{l=1}^{M} \alpha_{l} \sum_{j \in S_{nk}^{(i)}} \lambda_{ij}^{(l)} P_j \]
\[ = \sum_{j \in S_k^{(i)}} (\lambda_{ij} P_j) - \lambda_{k}^{(i)} - \lambda_{uc}^{(i)} \sum_{j \in S_{uc}^{(i)}} \lambda_{ij}^{(o)} P_j + \sum_{l=1}^{M} \alpha_{l} \sum_{j \in S_{nk}^{(i)}} \lambda_{ij}^{(l)} P_j \]
\[ = \sum_{j \in S_k^{(i)}} (\lambda_{ij} P_j) - \lambda_{k}^{(i)} - \lambda_{uc}^{(i)} \sum_{j \in S_{uc}^{(i)}} \lambda_{ij}^{(o)} P_j + \sum_{l=1}^{M} \alpha_{l} \sum_{j \in S_{nk}^{(i)}} \lambda_{ij}^{(l)} P_j, \]

Proof. Theorem 1 has given the sufficient condition that system (9) is stochastically admissible and has an \( H_{\infty} \)-performance indexes \( \gamma \) when the TRs are completely known. Next, we discuss the case that the state TRM contains unknown elements.

Case 1. If \( i \in S_k^{(i)} \cup S_{uc}^{(i)}, j \in S_{nk}^{(i)} \),
where $\tilde{\lambda}_{ij} (j \in S^{(i)}_{uk})$ and $\tilde{\lambda}_{ij} (j \in S^{(i)}_{uc})$ represent unknown and polytopic uncertain elements, respectively, $\Xi^{(i)}_{k} = \sum_{j \in S^{(i)}_{uk}} \tilde{\lambda}_{ij} P_{j}$, and $\Xi^{(i)}_{uc} = \sum_{j \in S^{(i)}_{uc}} \tilde{\lambda}_{ij} P_{j}$. Since $0 \leq \alpha_{i} \leq 1$, $\sum_{l=1}^{M} \alpha_{l} = 1$, and $0 \leq \tilde{\lambda}_{ij} / -\lambda_{k}^{(i)} - \lambda_{uc}^{(i)} \leq 1$, $\sum_{j \in S^{(i)}_{uc}} \tilde{\lambda}_{ij} / -\lambda_{k}^{(i)} - \lambda_{uc}^{(i)} = 1$, the right side (RS) of formula (40) can be written as

$$RS(50) = \sum_{l=1}^{M} \alpha_{l} \sum_{j \in S^{(i)}_{uk}} \frac{\tilde{\lambda}_{ij}}{-\lambda_{k}^{(i)} - \lambda_{uc}^{(i)}}(\Xi^{(i)}_{k} + \Xi^{(i)}_{uc} - (\lambda_{k}^{(i)} - \lambda_{uc}^{(i)}) P_{j}).$$

(41)

Similarly, when $0 \leq \alpha_{i} \leq 1$ and $0 \leq \tilde{\lambda}_{ij} \leq - (\lambda_{k}^{(i)} + \lambda_{uc}^{(i)})$, the left side (LS) of formula (18) can be transformed into the following form:

$$LHS(18) = \sum_{j=1}^{N} \frac{\tilde{\lambda}_{ij}}{-\lambda_{k}^{(i)} - \lambda_{uc}^{(i)}} \widetilde{\Omega}_{ij}, \quad j \in S^{(i)}_{uk}, i = 1, 2, \ldots, M,$$

(42)

where $\widetilde{\Omega}_{ij}$ has been defined in formula (39), which means that when not all elements are known in the TRM, the inequality set (17) is directly converted into the inequality set (37).

**Case 2.** If $i \in S^{(i)}_{uk}$, $j \in S^{(i)}_{uc}$.

When $0 \leq \alpha_{i} \leq 1$, $\tilde{\lambda}_{ij} = - (\lambda_{k}^{(i)} + \lambda_{uc}^{(i)})$, the elements in the $ith$ row are all known, so $0 \leq \alpha_{i} \leq 1, \tilde{\lambda}_{ij} < - (\lambda_{k}^{(i)} + \lambda_{uc}^{(i)})$ is true if at least one unknown element in the $ith$ row exists besides the diagonal. Under this condition, the $0 \leq \alpha_{i} \leq 1, \sum_{j=1}^{N} \tilde{\lambda}_{ij} P_{j}$ term in formula (18) can be rewritten as

$$\sum_{j=1}^{N} \lambda_{ij} P_{j} = \sum_{j \in S^{(i)}_{uk}} \lambda_{ij} P_{j} + \sum_{j \in S^{(i)}_{uc}, j \neq i} \tilde{\lambda}_{ij} P_{j} + \sum_{j \in S^{(i)}_{uc}, j \neq i} \sum_{l=1}^{M} \alpha_{l} \tilde{\lambda}_{il} P_{j}$$

$$= \Xi^{(i)}_{k} + \tilde{\lambda}_{ij} P + \sum_{j \in S^{(i)}_{uc}, j \neq i} \sum_{l=1}^{M} \alpha_{l} \Xi^{(i)}_{uc}.$$

(43)

Since $0 \leq \alpha_{i} \leq 1$, $\sum_{l=1}^{M} \alpha_{l} = 1$, and $0 \leq \tilde{\lambda}_{ij} / -\lambda_{k}^{(i)} - \lambda_{uc}^{(i)} \leq 1$, $\sum_{j \in S^{(i)}_{uc}, j \neq i} \tilde{\lambda}_{ij} / -\lambda_{k}^{(i)} - \lambda_{uc}^{(i)} = 1$; the following formula can be deduced:

$$\sum_{j=1}^{N} \sum_{l=1}^{M} \alpha_{l} \tilde{\lambda}_{ij} P_{j} = \sum_{l=1}^{M} \alpha_{l} \sum_{j \in S^{(i)}_{uc}, j \neq i} \tilde{\lambda}_{ij} / -\lambda_{k}^{(i)} - \lambda_{uc}^{(i)}$$

$$\left[\Xi^{(i)}_{k} + \tilde{\lambda}_{ij} P + \Xi^{(i)}_{uc} - (\lambda_{k}^{(i)} + \lambda_{uc}^{(i)}) P_{j}\right].$$

(44)

By rewriting the left side (LS) of inequality (18) according to equation (44), we can get

$$LS(18) = \sum_{l=1}^{M} \alpha_{l} \sum_{j \in S^{(i)}_{uc}, j \neq i} \frac{\tilde{\lambda}_{ij}}{-\lambda_{k}^{(i)} - \lambda_{uc}^{(i)}} \tilde{\Omega}_{ij}, \quad i \in S^{(i)}_{uk}, j \in S^{(i)}_{uc},$$

(45)

$$\tilde{\Omega}_{11} = \tilde{\Omega}_{11} + E^{T} \left[\Xi^{(i)}_{k} + \Xi^{(i)}_{uc} + \tilde{\lambda}_{ii} P_{i} - (\tilde{\lambda}_{ii} + \lambda_{k}^{(i)} + \lambda_{uc}^{(i)}) P_{j}\right] E,$$

(46)

where $\Omega_{i}$ has been defined in formula (39) and contains the term $\Omega_{11}$. In order to achieve the solvability of the stability analysis, the lower bound of the unknown element $\tilde{\lambda}_{ii}$ is defined as $\lambda_{b}^{(i)}$, and $\lambda_{b}^{(i)} \leq \tilde{\lambda}_{ii} \leq - \lambda_{k}^{(i)} - \lambda_{uc}^{(i)}$ can be obtained. It indicates that, for any small $\epsilon > 0$, $\tilde{\lambda}_{ii}$ can take value in the interval $[\lambda_{b}^{(i)}, - (\lambda_{k}^{(i)} + \lambda_{uc}^{(i)} + \epsilon)]$, then $\tilde{\lambda}_{ii}$ can be written as the form of the following convex combination $\tilde{\lambda}_{ii} = - \beta \lambda_{k}^{(i)} - \beta \lambda_{uc}^{(i)} + \beta \epsilon + (1 - \beta) \lambda_{b}^{(i)}$ where $0 \leq \beta \leq 1$, and it can be seen that $\tilde{\lambda}_{ii}$ depends linearly on $\beta$. Therefore, if only $\beta$ takes the boundary value of $0$ or $1$ that the linear solvable condition of inequality (45) can be satisfied. At this time, equation (46) can be rewritten as

$$\Omega_{11} = \Omega_{11} + E^{T} \left[\Xi^{(i)}_{k} + \Xi^{(i)}_{uc} + \lambda_{k}^{(i)} P_{i} - (\lambda_{k}^{(i)} + \lambda_{uc}^{(i)}) P_{j}\right] E,$$

(47)

$$\Omega_{11} = \Omega_{11} + E^{T} \left[\Xi^{(i)}_{k} + \Xi^{(i)}_{uc} - (\lambda_{k}^{(i)} + \lambda_{uc}^{(i)}) P_{j} + \epsilon (P_{i} - P_{j})\right] E,$$

(48)

When $\epsilon$ is infinitely small and $j \neq i$, $j \in S^{(i)}_{uc}$, formula (48) can be converted to

$$\Omega_{11} = \tilde{\Omega}_{11} + E^{T} \left[\Xi^{(i)}_{k} + \Xi^{(i)}_{uc} - (\lambda_{k}^{(i)} + \lambda_{uc}^{(i)}) P_{j}\right] E, \quad j \neq i.$$

(49)

When $j = i$, $j \in S^{(i)}_{uc}$, equation (47) can be written as (49), so when $i \in S^{(i)}_{uk}$ and $j \in S^{(i)}_{uc}$, the term $\Omega_{11}$ can be expressed by (47). The inequality group (17) can be directly converted into the inequality group (38). Therefore, when the elements in the state TRM are not completely known, as long as the inequality set (37)–(39) exists, system (9) is still stochastically admissible and has an $H_{\infty}$ performance index $\gamma$. The prove is completed.

**Remark 4.** In this section, stochastically admissible analysis criteria for a family of polytopic uncertain singular continuous-time Markovian jump error augmented systems with time-varying delays are given. Because the coupling terms in the system matrices will affect the performance of the FDFs, we will use a special method to design the full-order and reduced-order FDFs of polytopic uncertain CTSMJSSs with time-varying delays. It can improve the effectiveness and practicability of the FDFs.

### 4. Design of Full-Order and Reduced-Order FDFs for Polytopic Uncertain CTSMJSSs with Time-Varying Delays

**Theorem 3.** On the premise that the error augmented system (9) is stochastically admissible and has an $H_{\infty}$ performance index $\gamma$, for a given scalar $\gamma > 0$, exist positive definite symmetric
matrices $P_i := \begin{bmatrix} P_{i(1)} & KP_{i(2)} & P_{i(4)} \end{bmatrix} \in \mathbb{R}^{(n_1+m_1+m_2+\ldots+m_n+n)}$,

$\{Z_1, Z_2, R_1, R_2, Q_{11}, Q_{22}, Q_{33}\} \in \mathbb{R}^{n \times n}$, any appropriate dimensions matrices $\bar{S}, \bar{N}_i \in \mathbb{R}^{(n_1+m_1+m_2+\ldots+m_n+n) \times (n_1+m_1+m_2+\ldots+m_n+n)}$, and satisfying

$$E^T \bar{S} = 0, \quad \forall i, j \in I, \quad K = \left[I_{n_1} \ 0_{n_1 \times (n_2-n_1)}\right]^T,$$

the following linear matrix inequality sets are satisfied.

$$\begin{bmatrix} \Omega_{11} & \Omega_{12} & E^T \Phi R_i \Phi E & 0 & \Omega_{15} & \Omega_{16} & C_j^T \\ \Omega_{21} & \Omega_{22} & \Phi R_i \Phi E & 0 & \Omega_{26} & 0 & 0 \\ \Omega_{31} & \Omega_{33} & 0 & 0 & 0 & 0 & 0 \\ \Omega_{41} & \Omega_{44} & 0 & 0 & 0 & 0 & 0 \\ \Omega_{51} & \Omega_{55} & 0 & 0 & 0 & 0 & 0 \\ \Omega_{61} & \Omega_{66} & 0 & 0 & 0 & 0 & 0 \\ \end{bmatrix} < 0,$$

$$\begin{bmatrix} \bar{\Omega}_{11} & \bar{\Omega}_{12} & \bar{\Omega}_{13} \\ \bar{\Omega}_{21} & \bar{\Omega}_{22} & \bar{\Omega}_{23} \\ \bar{\Omega}_{31} & \bar{\Omega}_{32} & \bar{\Omega}_{33} \\ \end{bmatrix}^T,$$

$$\begin{bmatrix} \Omega_{15} & \Omega_{16} & \Omega_{17} \\ \Omega_{25} & \Omega_{26} & \Omega_{27} \\ \Omega_{35} & \Omega_{36} & \Omega_{37} \\ \end{bmatrix}^T,$$

$$\begin{bmatrix} \Omega_{12} & E^T P_{i(1)} A_d + E^T K P_{i(2)} C_d + N_i S^T A_d, \\ \Omega_{13} = E^T P_{i(1)} A_d B_p + E^T K P_{i(2)} C_d + P_{i(2)} B_p C_d, \\ \Omega_{15} = P_{i(4)}^T B_i, P_{i(4)}^T F_i, P_{i(5)} B_w f, \\ \end{bmatrix}^T,$$

$$\begin{bmatrix} \Omega_{11} & \Omega_{12} & \Omega_{13} \\ \Omega_{21} & \Omega_{22} & \Omega_{23} \\ \Omega_{31} & \Omega_{32} & \Omega_{33} \\ \end{bmatrix}^T,$$

$$\begin{bmatrix} \Omega_{15} & \Omega_{16} & \Omega_{17} \\ \Omega_{25} & \Omega_{26} & \Omega_{27} \\ \Omega_{35} & \Omega_{36} & \Omega_{37} \\ \end{bmatrix}^T,$$

$$\begin{bmatrix} \Omega_{12} & \Omega_{13} & \Omega_{14} \end{bmatrix}^T,$$

$$\begin{bmatrix} \Omega_{15} & \Omega_{16} & \Omega_{17} \\ \Omega_{25} & \Omega_{26} & \Omega_{27} \\ \Omega_{35} & \Omega_{36} & \Omega_{37} \\ \end{bmatrix}^T,$$

$$\begin{bmatrix} \Omega_{12} & \Omega_{13} & \Omega_{14} \end{bmatrix}^T,$$

$$\begin{bmatrix} \Omega_{15} & \Omega_{16} & \Omega_{17} \\ \Omega_{25} & \Omega_{26} & \Omega_{27} \\ \Omega_{35} & \Omega_{36} & \Omega_{37} \\ \end{bmatrix}^T.$$
The gain matrices \((A_{Fi}, B_{Fi}, C_{Fi}, D_{Fi})\) of fault detection filter (7) of system (1) can be obtained, and its parameter matrices are expressed as follows:

\[
A_{Fi} = P_{i(2)}^{-1} \overrightarrow{A}_{Fi}, \\
B_{Fi} = P_{i(2)}^{-1} \overrightarrow{B}_{Fi}, \\
C_{Fi} = \overrightarrow{C}_{Fi}, \\
D_{Fi} = \overrightarrow{D}_{Fi}.
\]  

(51)

Proof. In order to design high-performance full-order and reduced-order FDFs that meets the requirements, the Lyapunov matrix \(P_i\) in Theorem 1 has the following form:

\[
P_i := \begin{bmatrix}
P_{i(1)} \quad K P_{i(2)} \quad P_{i(4)} \\
* \quad P_{i(3)} \quad 0 \\
* \quad * \quad * 
\end{bmatrix},
\]  

(52)

where \(K := [I_{n_i} \quad 0_{n_i \times (n_i - n_x)}]^{T}\), \(P_{i(1)} \in R_{n_x \times n_x}, P_{i(2)} \in R_{n_n \times n_x}, P_{i(3)} \in R_{n_y \times n_n},\) and \(P_{i(4)} \in R_{n_n \times n_n}.\)

By using diagonal matrices \(\text{diag}\{I_{n_x}, P_{i(2)}, P_{i(4)}^{-1}\}\) and \(\text{diag}\{I_{n_y}, P_{i(3)}^{-1}, P_{i(4)}^{-1}\}\) to perform the congruent transformation of (52), we can get

\[
\begin{bmatrix}
I_{n_x} \quad 0 \quad 0 \\
* \quad P_{i(2)}^{-1} P_{i(3)} \quad 0 \\
* \quad * \quad I_{n_y} 
\end{bmatrix}
\begin{bmatrix}
P_{i(1)} \quad K P_{i(2)} \quad P_{i(4)} \\
* \quad P_{i(3)} \quad 0 \\
* \quad * \quad I_{n_y} 
\end{bmatrix}
= \begin{bmatrix}
P_{i(1)} \quad K \overrightarrow{P}_{i(2)} \quad P_{i(4)} \\
* \quad P_{i(3)} \quad \overrightarrow{P}_{i(2)} \quad P_{i(4)} \\
* \quad * \quad P_{i(4)} 
\end{bmatrix}
= \begin{bmatrix}
P_{i(1)} \quad 0 \quad 0 \\
* \quad * \quad P_{i(3)} \quad 0 \\
* \quad * \quad P_{i(4)} 
\end{bmatrix}
\]  

(53)

Therefore, without loss of generality, Lyapunov matrix \(P_i\) can be specified as the following general form:

\[
P_i := \begin{bmatrix}
P_{i(1)} \quad K P_{i(2)} \quad P_{i(4)} \\
* \quad P_{i(2)} \quad 0 \\
* \quad * \quad P_{i(4)} 
\end{bmatrix}.
\]  

(54)

The matrix variable \(P_{i(2)}\) in (54) can be combined with the gain matrices \(A_{Fi}\) and \(B_{Fi}\) of the filter to form new matrices, as follows:

\[
\overrightarrow{A}_{Fi} = P_{i(2)} A_{Fi}, \quad B_{Fi} = P_{i(2)} B_{Fi}.
\]  

(55)

Equation (50) can be obtained by substituting (54) into equation (39). The proof is completed. \(\square\)

Remark 5. Theorem 3 presents a high efficiency method for designing fault detection filter for polytopic uncertain CTSMJSSs with time-varying delays that full-order and reduced-order FDFs can be expressed in a unified formula. In order to illustrate the effectiveness of the proposed approach, the following example will be used to verification.

5. Numerical Example

In this section, two examples are used to illustrate the practicability and effectiveness of our results.

Example 1. Consider the DC motor driving a load that switching is driven by a continuous-time Markov process \(\{r(t), t > 0\}\) [40, 41]. Similarly, by neglecting the DC motor inductance \(L_m\), let \(i(t), v(t),\) and \(\varpi(t)\) represent the electric current, the voltage, and the speed of the shaft at time \(t\), respectively. According to the basic electrical and mechanic laws, we have

\[
\begin{bmatrix}
\dot{\varpi}(t) = -\frac{b_i}{J_i} \varpi(t) + \frac{K_i}{J_i} i(t), \\
v(t) = K_m \varpi(t) + R_i (t),
\end{bmatrix}
\]  

(56)

where \(K_i, K_m,\) and \(R_i\) denote the torque constant, the electromotive force, and the electric resistor, respectively. \(J_i\) and \(b_i\) are defined as \(J_i = J_m + J_{cl}/n^2\) and \(b_i = b_m + b_{cl}/n^2\), where \(J_{cl}\) and \(J_m\) represent the moments of the load and the motor, respectively, and \(b_m\) and \(b_{cl}\) stand for the damping ratios with gear ratio \(n\). Set \(x_1(t) = \varpi(t)\) and \(x_2(t) = i(t)\), and system (56) is expressed as

\[
\begin{bmatrix}
1 & 0 \\
0 & 0
\end{bmatrix}
\dot{x}(t) = \begin{bmatrix}
\frac{b_i}{J_i} K_i & 0 \\
0 & K_m
\end{bmatrix} x(t) + \begin{bmatrix}
0 \\
1
\end{bmatrix} v(t).
\]  

(57)

To guarantee the system stability, in this paper, we use the state feedback controller \(v(t) = K_i x(t)\) and value \(K_i = [-1.90832 - 2.77715]\) and \(K_m = [-2.3635 - 2.8652]\) in [39, 40]. Without loss of generality, as used in [41], \(K_m\) is assumed that time delay \(d(t) = 0.1 + 0.05 \sin 2t\) and system (57) can be written as

\[
\begin{bmatrix}
1 & 0 \\
0 & 0
\end{bmatrix}
\dot{x}(t) = \left(\begin{bmatrix}
\frac{b_i}{J_i} K_i & 0 \\
0 & K_m
\end{bmatrix} + \begin{bmatrix}
0 \\
1
\end{bmatrix} K_i \right) x(t)
\]  

(58)

To ensure the validity of the actual example, we will use the parameters in [40, 41], where \(J_m = 0.5k\cdot m, J_{cl} = 50k\cdot g\cdot m, J_{cs} = 150k\cdot g\cdot m, b_{cl} = 100, b_{cs} = 240, R_i = 1, b_m = 1, K_i = 3N\cdot m/A, K_m = 1V\cdot s/rad, n = 10,\) and
\[ \Pi = \begin{bmatrix} -0.0193 & 0.0193 \\ 0.0307 & -0.0307 \end{bmatrix} , \] and the following closed-loop system can be obtained:

\[ E \dot{x}(t) = A(r(t))x(t) + A_d(r(t))x(t - d(t)), \quad (59) \]

where \( E = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix} \), \( A_1 = \begin{bmatrix} -2.0000 & 3.0000 \\ -0.9083 & -1.7715 \end{bmatrix} \), \( A_2 = \begin{bmatrix} -1.7000 & 1.5000 \\ -1.3635 & -1.8652 \end{bmatrix} \), and \( A_{d1} = A_{d2} = \begin{bmatrix} 0 & 0 \\ 0.5 & 0 \end{bmatrix} \).

In order to design the full-order and reduced-order FDFs about system (59), the other parameters in [41] are given as:

\[ B_1 = [-2.5; -0.3], \]
\[ B_2 = [1.5; -0.2], \]
\[ E_1 = [-0.2; -0.1], \]
\[ E_2 = [0.15; -0.12], \]
\[ F_1 = [-0.5; 0.4], \]
\[ F_2 = [0.6; 0.3], \]
\[ C_1 = [-0.5 1.2], \]
\[ C_2 = [-0.35 0.7], \]
\[ C_{d1} = [-0.5 -1.6], \]
\[ C_{d2} = [-0.36 0.8], \]
\[ D_1 = 1.2, \]
\[ D_2 = 0.25, \]
\[ H_1 = 2, \]
\[ H_2 = -0.5, \]
\[ A_{w1} = -5, \]
\[ B_{w1} = 3, \]
\[ C_{w1} = 1, \]
\[ D_{w1} = 0. \]

By Theorem 3, letting \( S = [0; 1] \) and \( \gamma = 2 \), we can get the parameters of the desired full-order and reduced-order FDFs, which are given as follows.

(1) Parameter matrices of full-order FDF:

\[ A_{F1} = \begin{bmatrix} -0.8590 & 0.2076 \\ -0.0525 & -1.3138 \end{bmatrix}, \]
\[ B_{F1} = [0.2362; 0.0058], \]
\[ C_{F1} = [-0.0602 0.0866], \]
\[ D_{F1} = [0.1134], \]
\[ A_{F2} = \begin{bmatrix} -0.8447 & 0.7543 \\ -0.5808 & -1.3574 \end{bmatrix}, \]
\[ B_{F2} = [0.1068; 0.4773], \]
\[ C_{F2} = [-0.0152 0.0299], \]
\[ D_{F2} = [-0.3351]. \]

(2) Parameter matrices of reduced-order FDF:

\[ A_{F1} = [-4.9187], \]
\[ B_{F1} = [1.3578], \]
\[ C_{F1} = [-0.0714], \]
\[ D_{F1} = [0.1160], \]
\[ A_{F2} = [-2.6482], \]
\[ B_{F2} = [0.3304], \]
\[ C_{F2} = [-0.0165], \]
\[ D_{F2} = [-0.3374]. \]

**Remark 6.** Compared with [41], the proposed approach in this paper can not only solve the parameters of full-order FDF for DC motor but also figure out the parameters of reduced-order FDF. However, when the DC motor driving a load that switching is driven to start with the TRs have unknown elements and many uncertain elements, the proposed method is also practical. The following examples will further illustrate the effectiveness of the proposed method for FDFs design for different TRMs. We compare and analyse the \( H_\infty \) performance index \( \gamma_{\text{min}} \) and the number of decision variables of full-order and reduced-order FDF for four different TRMs.

**Example 2.** In this section, we select a system with four modals to verify the effectiveness of the designed full-order and reduced-order FDFs of CTSMJSs with time-varying delays and four different TRMs. The parameters matrices can be described as follows:
To make the convenience of simulation, the weighted fault frequency function and known control input signal to be set as $W_f(s) = 3/s + 5$ and $w(t) = 0.1 + 0.05 \cos(t)$, the Gaussian white noise signal with amplitude less than 0.2 is selected as the exogenous disturbance input $w(t)$, respectively. The range of time-varying delay $d(t)$ satisfies $0.1 \leq d(t) \leq 0.6$ and $d(t) \leq 0.3$ for $0 \leq t \leq 0.6$. In this paper, the simulation example selects the fault expression $f(t)$ that was used in many classic papers as the potential fault signal $[31-34]$. The fault detection graph simulated by this fault expression is not only simple but also clear; we can clearly see whether the fault detection filter is effective or not. The fault signal $f(t)$ is
tf(t)=\begin{cases} 1.5, & 20 \leq t \leq 40, \\ 0, & \text{others.} \end{cases} \quad (64)

Table 1 lists the four different cases TRMs, and Figure 1 shows the simulation results of four different cases Markov chain $r(t)$ evolution processes.

For Case 2, all the rows remain the same except for the third row, it contains two uncertain TRs, which means the TRM includes two vertices $A_{3(1)}$ and $s = 1, 2$ in third rows, and the TRM in the third row can be expressed as

$$A_{3(1)} = \begin{bmatrix} 0.4 & \hat{\lambda}_{32} & -1.3 & \hat{\lambda}_{34} \end{bmatrix}, \quad A_{3(2)} = \begin{bmatrix} 0.6 & \hat{\lambda}_{32} & -1.1 & \hat{\lambda}_{34} \end{bmatrix} \quad (65)$$

At the same time, we set the lower bounds $\hat{\lambda}_{32} = -1$ of unknown diagonal elements $\lambda_{32}$ in Case 2; set $\hat{\lambda}_{32} = -1$ in Case 3; and assign $\hat{\lambda}_{32} = -0.8$, $\hat{\lambda}_{32} = -1.2$, $\hat{\lambda}_{32} = -1.3$, and $\hat{\lambda}_{32} = -0.7$ in Case 4, respectively.

When the system parameters are presented, the linear matrix inequalities in Theorem 3 can be solved by MATLAB, and the full-order and reduced-order FDFs parameter matrices for four different cases of TRMs can be obtained as follows.

Case 1. TRM is completely known.

(1) Parameter matrices of full-order FDF with completely known TRM:

$$A_{F1} = \begin{bmatrix} -2.3922 & 0.1886 \\ 0.3139 & -3.5091 \end{bmatrix},$$

$$B_{F1} = \begin{bmatrix} -0.8997 & 1.2641 \end{bmatrix},$$

$$C_{F1} = \begin{bmatrix} -0.1449 & 0.1438 \end{bmatrix},$$

$$D_{F1} = [0.1801],$$

$$A_{F2} = \begin{bmatrix} -2.3114 & 2.0323 \\ -1.7332 & -2.7174 \end{bmatrix},$$

$$B_{F2} = [0.5977; -0.7239],$$

$$C_{F2} = [-0.0860; -0.1613],$$

$$D_{F2} = [-0.0504],$$

$$A_{F3} = \begin{bmatrix} -2.3830 & -0.3480 \\ 0.1603 & -3.8508 \end{bmatrix},$$
Case 2. TRM is polytopic uncertain.

(1) Parameter matrices of full-order FDF with polytopic uncertain TRM:

\[ B_{F3} = [-1.3546; -0.6935], \]
\[ C_{F3} = [-0.1584; -0.1482], \]
\[ D_{F3} = [0.2610], \]
\[ A_{F4} = [-1.4610; 0.0310; -0.0857; -2.3989], \]
\[ B_{F4} = [1.5553; -0.4436], \]
\[ C_{F4} = [-0.2164; -0.0215], \]
\[ D_{F4} = [-0.2857]. \]  

(2) Parameter matrices of reduced-order FDF with completely known TRM:

\[ A_{F1} = [-2.8377], \]
\[ B_{F1} = [-1.0126], \]
\[ C_{F1} = [-0.1645], \]
\[ D_{F1} = [0.1884], \]
\[ A_{F2} = [-2.6302], \]
\[ B_{F2} = [0.4328], \]
\[ C_{F2} = [-0.0973], \]
\[ D_{F2} = [-0.0482], \]  
\[ A_{F3} = [-2.6505], \]
\[ B_{F3} = [-1.2617], \]
\[ C_{F3} = [-0.2041], \]
\[ D_{F3} = [0.2795], \]
\[ A_{F4} = [-0.9532], \]
\[ B_{F4} = [1.0858], \]
\[ C_{F4} = [-0.2087], \]
\[ D_{F4} = [-0.3146]. \]  

\[ A_{F1} = \begin{bmatrix} -1.0126 & 0.0893 \\ -0.0672 & -1.8273 \end{bmatrix}, \]
\[ B_{F1} = [-0.0499; 0.8281], \]
\[ C_{F1} = [-0.1424; 0.0691], \]
\[ D_{F1} = [0.0739], \]
\[ A_{F2} = \begin{bmatrix} -0.9554 & 0.4547 \\ -0.4769 & -1.2196 \end{bmatrix}, \]
\[ B_{F2} = [-0.0562; 0.4387], \]
\[ C_{F2} = [-0.0964; -0.0333], \]
\[ D_{F2} = [0.0367], \]
\[ A_{F3} = \begin{bmatrix} -1.1803 & -0.0917 \\ 0.0210 & -1.8310 \end{bmatrix}, \]
\[ B_{F3} = [-0.6052; -0.3351], \]
\[ C_{F3} = [-0.0943; -0.0407], \]
\[ D_{F3} = [0.1409], \]
\[ A_{F4} = \begin{bmatrix} -0.9007 & 0.1558 \\ -0.1743 & -2.3419 \end{bmatrix}, \]
\[ B_{F4} = [-0.2081; -0.1826], \]
\[ C_{F4} = [-0.1404; 0.0017], \]
\[ D_{F4} = [-0.0472]. \]  

Case 3. TRM is partly unknown.

(1) Parameter matrices of full-order FDF with partly unknown TRM:
Table 1: TRMs of four different cases.

| Case 1: completely known TRM | Case 2: polytopic uncertain TRM | Case 3: partly unknown TRM | Case 4: completely unknown TRM |
|-------------------------------|-------------------------------|--------------------------|-------------------------------|

Remark 7. According to Theorem 3 and the simulation results, we can obtain that the selection dimension of $P_{(2)}(2) \in R^{n_f \times n_f}$ is the key to obtain the parameters of the full-order and reduced-order FDFs. When $n_f = n_x$, the parameters of the full-order FDF can be determined. When $n_f < n_x$, the parameters of the reduced-order FDF can be determined. For simplicity, the parameter matrices selected in this paper are two-dimensional, so only one-dimensional reduced-order FDF parameters are simulated. The method for determining the parameters of the reduced-order FDF is suitable for multidimensional matrices. By adjusting the dimensions of $P_{(2)}$, the parameters of the reduced-order FDF of different dimensions can be obtained. For example, when the parameter matrices of the full-order fault detection filter are three-dimensional, the one-dimensional and two-dimensional parameter matrices of reduced-order FDFs can be obtained, respectively. 

For convenience of simulation, the shortest time step $L_{\text{min}}$ is set as $J(\hat{r}(t)) > J_{\text{th}}$, $N_{DV}$ represents the number of decision variables, where $J_{\text{th}} = \sup_{0 \leq t \leq L_{\text{min}}; \delta \neq 0} \mathbb{E}[\int_{k_0}^{k_0+L} \hat{r}(t)\hat{r}(t)dt]$, and the minimum $H_{\infty}$ performance is $\gamma_{\text{min}}$. Next, we will illustrate the effectiveness of the full-order and reduced-order FDFs for four different cases of TRM by simulation analysis and parameter comparison lists.

Figures 2 and 3 demonstrate residual generation of full-order and reduced-order FDFs for four different TRMs cases, respectively. Obviously, it can be seen by residual
curve of comparison in Figures 3 and 4 that the estimated residual value of the full-order filter is nearer to the weighting fault signal than the estimated residual value of the reduced-order filter. The more the known transition rates are in the TRM, the more accurate the estimated residual values are. Case 2 with polytopic uncertainty TRM is obviously closer to the actual residual value than Case 3 and Case 4. The simulation results further indicate that no matter which case TRM is to be chosen, the designed FDFs are effective and feasible.

Figures 4 and 5 demonstrate the residual evaluation function curves of full-order and reduced-order FDFs for four different TRM cases, respectively. It can be seen from Figures 4 and 5 that the shortest time step $L_{\text{min}}$ is close to 20 (s), when $J(\tilde{r}(t)) > J_{\text{th}}$, that the weighting fault signal is effective and can improve the performance of the fault detection system. By comparing and analysing residual evaluation function curves of different FDFs and different cases of TRMs, we can draw a conclusion that Case 2 with polytopic uncertain TRM is closer to Case 1 with completely known TRM than Case 3 and Case 4, and the residual evaluation function value of the reduced-order FDF is obviously smaller than that of the full-order FDF and the evaluation time is obviously shortened.

Remark 8. This time(s) represents the shortest time for obtaining $H_\infty$ performance level $\gamma_{\text{min}}$, but the value of this
Table 2: Performance comparison results for four different cases of full-order FDFs with time-varying delays.

| TRM | \(d(t) = 0.4\) | \(t = 60\) | \(d(t) = 0.6\) | \(t = 60\) |

time is not obtained at one time, by calculating the average value that 50 times of data are obtained on the same computer. 

Tables 2 and 3 show the performance comparing full-order and reduced-order FDFs for the cases of different delay differentials. By comparing Table 2 with Table 3 filters characteristics, we can conclude the following:

(1) Under the condition of the same-order FDFs for different TRMs, the more known transition rates are in the TRM that the \(H_{\infty}\) performance level \(y_{\min}\) and the conservativeness are less

(2) Under the condition of the same-order FDFs and same TRMs, as the time-varying delays differential value increases, the time to solve \(y_{\min}\) significantly increased

(3) Compared with different-order FDFs of the same TRMs, the \(H_{\infty}\), performance index \(y_{\min}\) and the conservativeness are almost the same, but the number of decision variables (\(N_{DV}\)) reduced-order FDF is obviously less than full-order FDF; moreover, the processing speed of reduced-order FDF is faster than full-order FDF

6. Conclusions

In this paper, we propose full-order and reduced-order FDF design methods for CTSMJSs with time-varying delays and polytopic uncertain TRM. Based on the Lyapunov–Krasovskii functional method and convex optimization technique, some delay-dependent sufficient conditions are obtained such that the singular model error augmented system is stochastically admissible with an \(H_{\infty}\) performance \(y_{\min}\). Finally, two examples are presented to illustrate the effectiveness of the proposed design approach. Moreover, the issue of semi-Markovian jump systems [42, 43] is a promising research topic which has a strong practical background. In future, we will study the fault detection of semi-Markovian jump systems.
