(Dated: March 17, 2014)

We point out that the hypothesis of a \(SU(5)\)-like supersymmetric Grand Unified Theory (GUT) implies a generic relation within the flavour structure of up-type squarks. Contrary to other well-known \(SU(5)\) relations between the down-quark and charged lepton sectors, this relation remains exact in the presence of any corrections and extra operators. Moreover it remains valid to a good precision at the electroweak scale, and opens thus new possibilities for testing \(SU(5)\)-like GUTs. We derive the low-energy effective theory of observable light up-type squarks, that also constitutes a useful tool for squark phenomenology. We use this effective theory to determine how to test the hypothesis of a \(SU(5)\)-like GUT theory. The techniques of charm-tagging and top-polarimetry are a crucial ingredient of these tests.

PACS numbers:

INTRODUCTION

One of the most fascinating features of the Standard Model of Particles (SM) is that the matter fields fit into complete representations 10 and 5 of the \(SU(5)\) gauge group, as 10 = \((Q, U, E)\), 5 = \((L, D)\) [1]. This suggests that the SM is the low-energy effective theory (EFT) of a \(SU(5)\)-like Grand Unified Theory (GUT) – either \(SU(5)\), symmetric or containing \(SU(5)\) as a subgroup (see [2] and the reviews [3]). Many classes of \(SU(5)\)-like GUTs exist, with a variety of low-energy features. From the viewpoint of testing whether or not Nature is microscopically \(SU(5)\)-symmetric, this model-dependence is an irreducible theoretical uncertainty. It is thus highly challenging to find how to test the \(SU(5)\) hypothesis in a way as model-independently as possible.

In this Letter we point out a so-far unexplored \(SU(5)\) property confined to the up-squark sector, that is much less sensitive to model-dependence than previous, well-studied properties. This property arises in the flavour structure of up squarks, and its persistence at the weak scale is closely checked. We then derive the up-squark effective theory, applicable whenever unobserved squarks are assumed to be heavy. We use it to determine the most direct way to test the \(SU(5)\) hypothesis using our new relations, focussing on the light-stops scenario – that is favoured by LHC and consistent with Natural SUSY.

A NEW RELATION IN THE UP-SQUARK SECTOR

Besides gauge-coupling unification at the GUT scale, matter field unification implies the famous relation

\[ y_d = y_t \]  

between down quark and lepton Yukawa couplings. This relation is exact up to GUT scale threshold corrections that arise from integrating out heavy GUT states. In addition, the renormalization group (RG) flow down to the weak scale has to be taken into account, such that \(y_d - y_t\) unification is not straightforward and has generated a lot of literature (see [2] and many subsequent works).

Grand Unified Theories are closely linked to supersymmetry (SUSY), which strikingly favours the gauge coupling unification in its most simple realizations (MSSM, NMSSM) as well as in more evolved hypothesis (e.g. extra-dimensions, extra \(SU(5)\)-like matter [4]). In SUSY \(SU(5)\)-like GUTs, the two Higgs supermultiplets, denoted \(H_1, H_2\) (\(\equiv H_d, H_u\)), need to be embedded in a 5 and a 5 representation respectively, denoted \(H_1\) and \(H_2\). Interactions between matter and Higgses are given by the superpotential

\[ W = \lambda^u_{ij} H_1 10_{ij}, 5_{j} + \lambda^d_{ij} H_2 10_{ij}, 10_{j}. \]  

Below the GUT scale, assuming that unwanted Higgs triplets are heavy due to some splitting mechanism [3,7], the superpotential reads

\[ W = y_d^U H_2 Q U_j + y_d^D H_1 Q D_j + y_t^L H_1 L_i E_j. \]  

where \(y_d = y_t = \lambda_1\). Furthermore, SUSY needs to be broken around the TeV scale, and the Lagrangian also contains the SUSY-breaking scalar trilinear terms \(a_{u,d,\ell}\),

\[ \mathcal{L}_{\text{soft}} \supset a_u h_u q \tilde{u} + a_d h_d q \tilde{d} + a_\ell h_\ell \tilde{\ell} \tilde{\ell}, \]  

where \(h_{u,d}\) are the two Higgs doublets and \(\tilde{q}, \tilde{u}, \tilde{d}, \tilde{\ell}, \tilde{\ell}\) are the squarks and sleptons. The Lagrangian also contains five scalar mass terms denoted by \(m^2_{Q,U,D,L,E}\) (see, e.g., [3]).
With the assumption that the source of SUSY breaking is $SU(5)$-symmetric, the above terms satisfy the relations
\[ a_d = a_l^t, \quad m_{Q}^2 = m_{U}^2 = m_{E}^2, \quad m_{L}^2 = m_{D}^2 \] (5)

at the GUT scale, which are exact up to GUT threshold corrections.

The correlations that the $SU(5)$ relations (5) induce between the quark and lepton sectors have been extensively studied within specific GUT scenarios [10]. Such correlations, although certainly interesting in specific models, can be hardly used as a generic test of the $SU(5)$ hypothesis, as RG corrections received by quark and leptons are fundamentally different.

We now point out the existence of relation implied by the $SU(5)$ matter embedding, which seems unnoticed so far. The $10,10_j$ term in the superpotential (2) is symmetric, such that only the symmetric part of $\lambda_{ij}^5$ is selected. This leads to a symmetric top Yukawa coupling at the GUT scale,
\[ y_{u} = y_{u}^t. \] (6)

Moreover, in presence of SUSY, this enforces that the trilinear coupling is also symmetric,
\[ a_{u} = a_{l}^t. \] (7)

These relations are confined within the up-(s)quark flavour space, and can thus be expected to be more stable against quantum corrections than the quark-lepton relations. Moreover, these relations remain rigorously exact in presence of any GUT threshold corrections, because the up-squark self-energy gets in any case contracted with $10,10_j$, and is therefore always symmetric [18].

For a non-SUSY theory, Eq. (5) does not seem particularly exploitable. In this case the only physical parameters are mass eigenvalues and CKM angles, and these would not be enough to find out whether or not $y_{u}$ is symmetric. The situation becomes different once one considers broken SUSY, because more degrees of freedom of the Yukawa matrices are probed by the superpartners.

**THE UP-SQUARK MASS MATRIX**

Let us see how our new $SU(5)$ relations translate into observable properties. As the relations (5) and (7) hold within the up-squark sector, we need to scrutinize the up-squark mass term $\mathcal{L} \supset \bar{u}^t M_{u}^2 \bar{u}$, where $\bar{u} = (\bar{u}_L, \bar{c}_L, \bar{l}_L, \bar{u}_R, \bar{c}_R, \bar{l}_R)^t$ contains the six up-squarks states.

In the super-CKM basis, defined such that the Yukawa matrices are diagonal, the up-squark mass matrix has the form
\[ \mathcal{M}_{u}^2 = \begin{pmatrix} m_{11}^2 & m_{12}^2 & m_{13}^2 & m_{14}^2 & m_{15}^2 & m_{16}^2 \\ m_{21}^2 & m_{22}^2 & m_{23}^2 & m_{24}^2 & m_{25}^2 & m_{26}^2 \\ m_{31}^2 & m_{32}^2 & m_{33}^2 & m_{34}^2 & m_{35}^2 & m_{36}^2 \\ m_{41}^2 & m_{42}^2 & m_{43}^2 & m_{44}^2 & m_{45}^2 & m_{46}^2 \\ m_{51}^2 & m_{52}^2 & m_{53}^2 & m_{54}^2 & m_{55}^2 & m_{56}^2 \\ m_{61}^2 & m_{62}^2 & m_{63}^2 & m_{64}^2 & m_{65}^2 & m_{66}^2 \end{pmatrix}. \] (8)

where $M$ denotes the SUSY scale. In general, $\hat{a}_u = W^\dagger a_u W$, $\hat{m}_{Q}^2 = V^\dagger m_{Q}^2 V$, $\hat{m}_{D}^2 = W^\dagger m_{D}^2 W$, with $y_{u} = V^{\dagger} y_{u} W$, $\hat{y}_{u}$ diagonal. The mass matrix $\mathcal{M}_{u}^2$ involves only $a_{u}$, $m_{Q}^2$ and $m_{D}^2$, so that we do not have to consider the other SUSY-breaking terms at this stage. As the observables we are going to study are not sensitive to CP violation, we can take these parameters to be real without loss of generality.

The $SU(5)$ relation (5) implies $V^*_{u} = W_{u}$. Dropping the conjugates as all parameters are real, it appears that the $SU(5)$ relations are satisfied in the super-CKM basis, $\hat{a}_u = a_l^t$, $\hat{m}_{Q}^2 \approx \hat{m}_{D}^2$. The mass matrix $\mathcal{M}_{u}^2$ involves only $a_{u}$, $m_{Q}^2$ and $m_{D}^2$, so that we do not have to consider the other SUSY-breaking terms at this stage. As the observables we are going to study are not sensitive to CP violation, we can take these parameters to be real without loss of generality.

Therefore the up-squark mass matrix possesses a peculiar structure above the GUT scale. However below the GUT scale this structure is potentially spoiled by the non-$SU(5)$ quantum corrections. It is thus necessary to evaluate how stable the relations $a_{u} = a_l^t$ and $m_{Q}^2 \approx m_{D}^2$ remain upon the RG flow. This can be qualitatively verified using the two-loop RG equations of MSSM-like theories [11], see also [10]. The only sizeable discrepancy appears between the low-energy $m_{Q}^2_{13}$ and $m_{D}^2_{13}$. The other discrepancies are overall negligible with respect to other theoretical and experimental sources of uncertainty. This conclusion is confirmed by the numerical evaluations made in the next Section.

We parametrize the complete up-squark mass matrix as
\[ \mathcal{M}_{u}^2 = \begin{pmatrix} m_{11}^2 & m_{12}^2 & m_{13}^2 & m_{14}^2 & m_{15}^2 & m_{16}^2 \\ m_{21}^2 & m_{22}^2 & m_{23}^2 & m_{24}^2 & m_{25}^2 & m_{26}^2 \\ m_{31}^2 & m_{32}^2 & m_{33}^2 & m_{34}^2 & m_{35}^2 & m_{36}^2 \\ m_{41}^2 & m_{42}^2 & m_{43}^2 & m_{44}^2 & m_{45}^2 & m_{46}^2 \\ m_{51}^2 & m_{52}^2 & m_{53}^2 & m_{54}^2 & m_{55}^2 & m_{56}^2 \\ m_{61}^2 & m_{62}^2 & m_{63}^2 & m_{64}^2 & m_{65}^2 & m_{66}^2 \end{pmatrix}. \] (9)

The above low-energy $SU(5)$ relations, $a_{u} = a_l^t$ and $m_{Q}^2 \approx m_{D}^2$, then translate into
\[ m_{15} \approx m_{24}, \quad m_{16} \approx m_{23}, \quad m_{26} \approx m_{25}, \quad m_{15} \approx m_{24}, \quad m_{16} \approx m_{23}, \quad m_{26} \approx m_{25}, \] (10)
\[ m_{12} \approx m_{34}, \quad m_{13} \approx m_{35}, \quad m_{23} \approx m_{34}, \] (11)
\[ m_{11} \approx m_{34}, \quad m_{22} \approx m_{35}. \] (12)

**UP-SQUARK EFFECTIVE THEORY**

Although the pattern of squark masses is arbitrary in full generality, a likely situation is that the masses exhibit some hierarchy. This is favoured from naturalness considerations, from LHC bounds, as well as from certain classes of models. In such a situation the physics
of the light squarks can be conveniently captured into a low-energy effective theory, where heavy squarks are integrated out.

Let us reorganize the up-squark mass term such that

$$\mathcal{L} \supset \hat{u}^\dagger M_2^2 \hat{u} \equiv \Phi^\dagger M^2 \Phi = \left( \hat{\phi}^\dagger, \phi^\dagger \right) \begin{pmatrix} \hat{M}^2 & \hat{M}^2 \\ \hat{M}^2 & M^2 \end{pmatrix} \begin{pmatrix} \hat{\phi} \\ \phi \end{pmatrix},$$

where $\hat{\phi}$ contains the heavy states and $\phi$ the light ones. The relevant piece of the corresponding Lagrangian has the general form

$$\mathcal{L} \supset |D\phi|^2 - \Phi^\dagger M^2 \Phi + \left( \mathcal{O}_\phi + \mathcal{O}_\hat{\phi} + \text{h.c.} \right),$$

where $\mathcal{O}$ and $\mathcal{O}_\hat{\phi}$ represent the interactions with other fields, that are potentially exploited to probe the up-squark sector.

Assuming that the eigenvalues of $\hat{M}^2$ are large with respect to the energy at which one probes the theory, the heavy squarks $\hat{\phi}$ can be integrated out, leaving the low-energy Lagrangian of light squarks,

$$\mathcal{L}_{\text{eff}} = |D\phi|^2 + \left( \mathcal{O}_\phi - \mathcal{O}_\hat{\phi} (\hat{M}^2 - \hat{M}^4 - \hat{M}^2) \hat{M}^2 - \frac{\mathcal{O}}{2} \hat{M}^2 \hat{M}^4 - \hat{M}^4 \right) \phi + \text{h.c.} - \frac{\phi^\dagger (\hat{M}^2 - \hat{M}^4 \hat{M}^{-2} \hat{M}^2 - \frac{1}{2} \{ \hat{M}^2 \hat{M}^{-2} \hat{M}^2, M^2 \}) \phi}{\hat{M}^2},$$

In this effective Lagrangian we keep only the leading and the subleading terms of the $E^2 \hat{M}^{-2}$ expansion relevant for our purposes. Here, $E$ denotes the energy scale. It contains in principle higher dimensional couplings and derivative terms, which are either subleading or irrelevant for the observables we are going to consider, and are thus neglected. To obtain Eq. (13), one has to use the field redefinition $\Phi \rightarrow \left( 1 - \frac{1}{2} \hat{M}^2 \hat{M}^{-4} \hat{M}^2 \right) \Phi$ in order to canonically normalize the light squarks. The $\{ , \}$ is the anti-commutator.

The imprint of the heavy up-squarks in the light up-squarks Lagrangian (15) appears as corrections to the light up-squark masses and couplings. Physically, these corrections have to be understood both as tree-level exchange of heavy up-squarks, and as the first terms of the expansion with respect to the small parameters that describe mixing of heavy and light squarks. We emphasize that, although this effective theory approach might bear some resemblance with the “mass insertion approximation” (MIA), the two approaches are fundamentally different. The MIA is an expansion in the limit of small off-diagonal elements of the mass matrix $M^2$, i.e. in terms of small parameters $M^2_{ij}/\text{tr}(M^2)$. In contrast, the expansion parameter of the effective theory is $E^2 \hat{M}^{-2}$, and $M^2$ can have arbitrary off-diagonal entries.

From Eq. (15) we see that flavour-violating couplings of the light squarks enter at first order and are controlled by $\hat{M}^{-2} \hat{M}^2$. The flavour respecting couplings will be instead modified at the second order. The light mass matrix $M^2$ receives a correction independent of $M^2$ at first order, and corrections proportional to $M^2$ at second order.

**TESTING SU(5)-LIKE GUTS AT THE LHC: THE EXAMPLE OF TWO LIGHT-STOPs**

Armed with the up-squark effective Lagrangian, we are now ready to test the low-energy $SU(5)$ relations $a_u \approx a'_u$ and $m_Q^2 \approx m_Q^2$. In this Letter we focus on LHC physics, in the assumption that the lightest squarks are produced at the LHC, while the unobserved squarks are heavy such that the truncation of the effective Lagrangian is valid. Note that the expansion parameter behaves as the mass squared, such that for masses of, e.g., $m_\phi \approx 1$ TeV and $m_\phi \approx 3$ TeV, higher terms of the expansion are already suppressed by a factor of order 10.

Supersymmetric scenarios with two light squarks that are mainly stops, $\phi = (\tilde{t}_L, \tilde{t}_R)$, $\phi = (\tilde{u}_L, \tilde{c}_L, \tilde{u}_R, \tilde{c}_R)$ are favoured by LHC data and are one of the features of the Natural SUSY framework. For simplicity, we will in the following denote these two light squarks as “stops”. We consider $R$-parity conserving scenarios. We assume that both stops are copiously produced through flavor-diagonal processes. Indeed, gluon-initiated production of squark pairs will be the dominant production channel for squarks having a mass of about 1 TeV at the LHC with a center-of-momentum energy of 13 or 14 TeV.

The effective Lagrangian of the stops is obtained by expanding Eq. (15), where we introduce the parameters $m_\tilde{t}_{1,44} \equiv A_{1,44}$, $m_\tilde{t}_{2,55} \equiv A_{2,55}$. We observe that the stop mass matrix depends at the leading order on $m_{\tilde{t}_{\min,66,36}}$. There is no relevant information to test the $SU(5)$ hypothesis in this matrix, and the higher corrections to the mass matrix cannot be exploited either.

The stop mass eigenstates are $(\tilde{t}_L, \tilde{t}_R) = R(\theta) (\tilde{t}_L, \tilde{t}_R)^\dagger$, where $R(\theta)$ is a $SO(2)$ rotation with the stop mixing angle $\theta$. The stop mixing angle can be large and is a crucial feature of low-energy SUSY. Knowing its value will not be necessary in the following $SU(5)$ tests, although it will appear in intermediate steps.

The case $m_{\tilde{t}_{1,2}} > m_W > m_B$

As a first typical example, we consider the case where stops can decay both to the lightest neutralino, which is mostly bino-like, $\tilde{\chi}_1^0 \approx B$, and to a mostly wino-like second-lightest neutralino $\tilde{\chi}_2^0 \approx W$. This mass hierarchy is inspired by the fact that in GUTs we have the approximate relation $M_B \approx M_W/2$ at the weak scale.
Let us focus on the flavour-violating couplings of the stops, that appear at first order in Eq. (15). The operators that couple the stops to $\tilde{B}$ and $\tilde{W}$ in Eq. (15) are $\mathcal{O} \propto (u_Lc_L, -4u_R, -4c_R) \tilde{B}$ and $\mathcal{O} \propto (u_Lc_L) \tilde{W}$ at first order in the effective Lagrangian (15), the flavour-violating couplings of the stops are proportional to

$$\tilde{B} \left( \frac{m_1^2}{M_1} u_L + \frac{m_2^2}{M_2} c_L - 4 \frac{m_1^2}{M_1^2} u_R - 4 \frac{m_2^2}{M_2^2} c_R \right) R(\dot{\theta}) \left( \tilde{t}_1 \tilde{t}_2 \right),$$

$$\tilde{W} \left( \frac{m_1^2}{M_1} u_L + \frac{m_2^2}{M_2} c_L \right) R(\dot{\theta}) \left( \tilde{t}_1 \tilde{t}_2 \right).$$

(16)

(17)

The low-energy $SU(5)$ relations Eq. (10)-(12) directly relates these effective couplings. A numerical analysis shows that non-$SU(5)$ discrepancies induced by the RG flow are typically of order 1%. The stop decay chains of interest are $\tilde{t}_1, \tilde{t}_2 \rightarrow q \tilde{B}$ and $\tilde{t}_1, \tilde{t}_2 \rightarrow q \tilde{W} \rightarrow q Z/\gamma \tilde{B}$, where $q = u, c$ observed as hard jets. These two decays, occurring respectively through $U(1)_Y$ and $SU(2)_L$ interactions, are observed separately as hard jets. In the complete production-decay process, we ask for a flavour violating decay for one out of the two produced stops.

Let us first assume that one simply counts the amount of flavour-violating events occurring in the decays to $\tilde{B}$ and $\tilde{W}$, without disentangling between the nature of the jets nor between the original stops. It turns out that, whenever the $SU(5)$ hypothesis is verified, and for arbitrary stop mixing angle, both decay rates $N_{Y, L}$ and $N_{L}$ are controlled by the same combination of parameters, according to

$$N_{L,Y} \propto \left( \sigma_{t_1} \epsilon_2^2 + \sigma_{t_2} \epsilon_1^2 \right) \left( m_{13}^4 A_1^{-4} + m_{23}^4 A_2^{-4} \right)$$

$$+ \left( \sigma_{t_1} \epsilon_2^2 + \sigma_{t_2} \epsilon_1^2 \right) \left( m_{16}^4 A_1^{-4} + m_{26}^4 A_2^{-4} \right)$$

$$+ 2 \epsilon_0 \epsilon_1^2 \epsilon_2^2 \sigma_{t_1} - \sigma_{t_2} \left( m_{14}^2 m_{16}^2 A_1^{-4} + m_{23}^2 m_{26}^2 A_2^{-4} \right).$$

(18)

Here, $\sigma_{t_i}$ denotes the inclusive cross section of the flavour-conserving production process $pp \rightarrow \tilde{t}_i \tilde{t}_i^*$ at LHC.

It is thus, in principle, possible to test the $SU(5)$ hypothesis using these simple decay rates. However, estimating precisely the overall factors relating $N_L$ and $N_Y$ to the quantity (15) can be challenging because this requires to know the realistic cross-section including all the kinematic selections. This drawback can be avoided using charm-tagging techniques. The use of c-tagging allows to identify a fraction $N_{Y,L}$ of the jets due to c-quarks, where $N_{Y,L} = N_{Y,L}^{c} + N_{Y,L}^{u}$. The remaining fraction, $N_{Y,L}^{u}$ includes the jets that cannot be identified as c-quarks, i.e. up-quarks and mistagged charm-jets. As a result, whenever the $SU(5)$ hypothesis is fulfilled, the four decay rates $N_{Y,L}^{c}$ and $N_{Y,L}^{u}$ satisfy the relation

$$\frac{N_{Y,L}^{c}}{N_{L}} = \frac{N_{Y,L}^{u}}{N_{L}}.$$

(19)

Note that this test of the $SU(5)$ hypothesis does not require to know the stop-mixing angle, nor to have a precise estimation of the stop-production cross-sections.

The case $m_{t} > m_{1,2} > m_{\tilde{B}}$

As a second example, let us assume that the stops can only decay into the lightest neutralino $\chi_1^0 \approx \tilde{B}$. Using only the information from flavour-violating decays into $\tilde{B} + \text{jets}$, it turns out it is not possible to test the $SU(5)$ hypothesis, even if one disentangles the decays of $\tilde{t}_1$ and $\tilde{t}_2$, even if one disentangles the decays of $\tilde{t}_1$ and $\tilde{t}_2$ and knows the value of the stop mixing angle.

For this case, let us consider the flavour-conserving interactions of the stops. The relevant operator coupling to the stops in Eq. (15) is $\mathcal{O} \approx (t_L, -4t_R) \tilde{B}$. The decays of interest for our $SU(5)$ testing purpose are thus $\tilde{t}_1, \tilde{t}_2 \rightarrow B t_L, R$. For the stops decaying into top quarks, techniques of top polarimetry [14] potentially provide a way to distinguish between decays into top of left and right chirality, $t_L$ and $R$. Using kinematic information it is also possible to disentangle $t_1$ and $t_2$ decays. Considering that one can both distinguish between the original stops $t_1, t_2$ and the outgoing $t_L, t_R$, we end up with four observable decay rates $N_{1,1}, N_{1,2}, N_{2,1}, N_{2,2}$. At leading order, the matrix coupling the stops to $\mathcal{O}$ is unitary, $\mathcal{O}R(\dot{\theta})(t_1, t_2)^T$. The four decay rates satisfy thus two non trivial relations, conveniently chosen as

$$\frac{N_{1,1}}{N_{1,2}} = \frac{N_{2,2}}{16^2 N_{2,1}} \left( N_{1,1} \sigma_{t_1} + N_{2,1} \sigma_{t_2} \right) = \frac{N_{1,1}}{\sigma_{t_1}} + \frac{N_{2,2}}{\sigma_{t_2}} \frac{1}{2} \left( \frac{m_{13}^4}{\Lambda_1^2} + \frac{m_{23}^4}{\Lambda_2^2} + \frac{m_{14}^4}{\Lambda_1^2} + \frac{m_{24}^4}{\Lambda_2^2} \right).$$

(20)

Note that the various ratios of decay rates provide inequivalent measurements of the stop mixing angle. A third relation coming from the overall normalization also exists but is related to the total cross-section, that needs to be estimated precisely, and which is not necessary for our purpose of testing the $SU(5)$ hypothesis. The relevant information arises instead at next-to-leading order in the distortion of the coupling matrix in the stop effective theory. Whenever the $SU(5)$ hypothesis is true, the coupling takes the form

$$\tilde{B} \left( t_L, -4t_R \right) \left( \frac{1}{1-a} - \frac{-b}{-b 1-a} \right) R(\dot{\theta}) \left( \tilde{t}_1 \tilde{t}_2 \right)$$

(21)

with

$$a = \frac{1}{2} \left( \frac{m_{13}^4}{\Lambda_1^2} + \frac{m_{23}^4}{\Lambda_2^2} + \frac{m_{14}^4}{\Lambda_1^2} + \frac{m_{24}^4}{\Lambda_2^2} \right).$$

(22)
The correction to the coupling matrix in Eq. (21) induces a slight overall decrease in the stop decay rate. One quick way to see this is that the determinant of the coupling matrix is smaller than unity. This slight global decrease would probably be most difficult to detect because it requires a very good knowledge of the production cross-section including all cuts. The crucial signature lies instead in the matrix structure. If the SU(5) hypothesis is true, the distortion is symmetric, which implies that

$$N_{1, L} / N_{1, R} \neq 1 / 16^2 N_{2, L}, \quad 16 \left( \frac{N_{1, L}}{\sigma_1} + \frac{N_{2, L}}{\sigma_2} \right) = \frac{N_{1, R}}{\sigma_1} + \frac{N_{1, R}}{\sigma_1}.$$  

(24)

Instead, if the SU(5) hypothesis is not true, both relations are not satisfied. Again, this test uses only ratios of decay rates, and thus does not depend crucially on the overall normalization.

**SUMMARY**

In this Letter we point out the existence of SU(5)-like GUT relations that have remained unexplored so far. These new SU(5) relations are insensitive to GUT threshold corrections and are confined to the flavour structure of the up-sector quark, which makes them more stable with respect to quantum corrections than the other well-known SU(5) relations. Due to these features, the new relations open new ways to test whether Nature is microscopically SU(5)-symmetric. We focus on tests at the LHC using unprecedented simple tests involving the properties of up-type squarks.

We set up the effective theory for light up-type squarks, that is also a useful tool beyond our SU(5)-testing purpose. Using this effective theory, we study the case of two light stops, that is motivated by the Natural SUSY framework, to find set up tests of the SU(5) hypothesis. We show that fairly simple tests, independent of the stop mixing angle and involving only ratios of number of events, can be set up for various mass ordering scenarios. The techniques of charm-tagging and top polarimetry play a crucial role in these SU(5) tests. More evolved statistical techniques for arbitrary low-energy spectra will be presented [16].

[17] Note that some early models are excluded by proton decay [1].

[18] Note $y_s, a_t$ are symmetric, but generally not hermitian. Here, we assume them to be real since no CP-violating observables will be studied.

[19] We remind that it is not necessary to use eigenstates to perform this operation.
In particular to obtain a 125 GeV Higgs.
