LIMIT CYCLES FOR TWO CLASSES OF CONTROL PIECEWISE LINEAR DIFFERENTIAL SYSTEMS

JAUME LLIBRE\(^1\), REGILENE D. OLIVEIRA\(^2\) AND CAMILA AP. B. RODRIGUES\(^3\)

**Abstract.** We study the bifurcation of limit cycles from the periodic orbits of \(2n\)-dimensional linear centers \(\dot{x} = A_0 x\) when they are perturbed inside classes of continuous and discontinuous piecewise linear differential systems of control theory of the form \(\dot{x} = A_0 x + \varepsilon (Ax + \phi(x_1)b)\), where \(\phi\) is a continuous or discontinuous piecewise linear function, \(A_0\) is a \(2n \times 2n\) matrix with only purely imaginary eigenvalues, \(\varepsilon\) is a small parameter, \(A\) is an arbitrary \(2n \times 2n\) matrix, and \(b\) is an arbitrary vector of \(\mathbb{R}^n\).

1. **Introduction and statement of the main results**

In control theory are relevant the *continuous piecewise linear differential systems* of the form

\[
\dot{x} = Ax + \varphi(x_1)b,
\]

with \(A\) a \(m \times m\) matrix, \(x, b \in \mathbb{R}^m\), \(\varphi : \mathbb{R} \to \mathbb{R}\) is the continuous piecewise linear function

\[
\varphi(x_1) = \begin{cases} 
-1 & \text{if } x_1 \in (-\infty, -1), \\
x_1 & \text{if } x_1 \in [-1, 1], \\
1 & \text{if } x_1 \in (1, \infty),
\end{cases}
\]

where \(x = (x_1, \ldots, x_m)^T\), and the dot denotes the derivative with respect to the independent variable \(t\), the time.

Also in control theory are important the *discontinuous piecewise linear differential systems* of the form \([1]\) where instead of the function \(\varphi\) we have the discontinuous piecewise linear function

\[
\psi(x_1) = \begin{cases} 
-1 & \text{if } x_1 \in (-\infty, 0), \\
1 & \text{if } x_1 \in (0, \infty).
\end{cases}
\]

Key words and phrases. limit cycles; discontinuous piecewise linear differential system; bifurcation.
For more details on these continuous and discontinuous piecewise linear differential systems see for instance the books \[1, 3, 10, 11, 16, 18\].

The analysis of discontinuous piecewise linear differential systems goes back mainly to Andronov and coworkers \[2\] and nowadays still continues to receive attention by many researchers. In particular, discontinuous piecewise linear differential systems appear in a natural way in control theory and in the study of mechanical systems, electrical circuits, ... see for instance the book \[4\] and the references quoted there. These systems can present complicated dynamical phenomena such as those exhibited by general nonlinear differential systems.

One of the main ingredients in the qualitative description of the dynamical behavior of a differential system is the number and the distribution of its limit cycles. The goal of this paper is to study analytically the existence of limit cycles for a class of continuous and a class of discontinuous piecewise linear differential of the form \([1]\).

More precisely, first we consider the class of continuous piecewise linear differential systems

\[
\dot{x} = A_0 x + \varepsilon (Ax + \varphi(x_1)b),
\]

with \(|\varepsilon| \neq 0\) a sufficiently small real parameter, where \(A_0\) is the \(2n \times 2n\) matrix having on its principal diagonal the following \(2 \times 2\) matrices

\[
\begin{pmatrix}
0 & -(2k-1) \\
2k-1 & 0
\end{pmatrix}
\quad \text{for } k = 1, \ldots, n,
\]

and zeros in the complement, \(A\) is an arbitrary \(2n \times 2n\) matrix and \(b \in \mathbb{R}^{2n} \setminus \{0\}\). Note that for \(\varepsilon = 0\) system \((4)\) becomes

\[
\dot{x}_1 = -x_2, \quad \dot{x}_2 = x_1, \quad \ldots, \quad \dot{x}_{2n-1} = -(2n-1)x_{2n}, \quad \dot{x}_{2n} = (2n-1)x_{2n-1}.
\]

Moreover, the origin of \((5)\) is a global isochronous center in \(\mathbb{R}^{2n}\), i.e. all its orbits different from the origin are periodic with period \(2\pi\).

In a similar way we consider the discontinuous piecewise linear differential systems

\[
\dot{x} = A_0 x + \varepsilon (Ax + \psi(x_1)b),
\]

Our main results on the limit cycles of the continuous and discontinuous piecewise linear differential systems \([4]\) are the following ones.

**Theorem 1.** For \(|\varepsilon| > 0\) sufficiently small and if the conditions for applying the averaging theory of first order hold, then at most one limit cycle \(\gamma_\varepsilon\) of the continuous piecewise linear differential system \((4)\) bifurcates from the periodic orbits of system \((5)\), i.e. \(\gamma_\varepsilon\) tends to a periodic solution of system \((5)\) when \(\varepsilon \to 0\). Moreover there are systems \((4)\) with \(|\varepsilon| > 0\) sufficiently small having a such limit cycle.

Theorem \([1]\) is proved in section \([3]\)
**Theorem 2.** For $|\varepsilon| > 0$ sufficiently small and if the conditions for applying the averaging theory of first order hold, then at most one limit cycle $\gamma_\varepsilon$ of the discontinuous piecewise linear differential system (6) bifurcates from the periodic orbits of system (5). Moreover there are systems (6) with $|\varepsilon| > 0$ sufficiently small having a such limit cycle.

Theorem 2 is proved in section 4.

If instead of the matrix $A_0$ we consider the matrix $A_1$ where $A_1$ is the $2n \times 2n$ matrix having on its principal diagonal the following $2 \times 2$ matrices

$$
\begin{pmatrix}
0 & -k \\
 k & 0
\end{pmatrix}
$$

for $k = 1, \ldots, n$,

and zeros in the complement, then we have the following results.

**Theorem 3.** Assume that the conditions for applying the averaging theory of first order hold. Then this theory does not provide any information about the limit cycles of the continuous piecewise linear differential system

\begin{equation}
\dot{x} = A_1 x + \varepsilon (Ax + \varphi(x_1)b).
\end{equation}

**Theorem 4.** Assume that the conditions for applying the averaging theory of first order hold. Then this theory does not provide any information about the limit cycles of the discontinuous piecewise linear differential system

\begin{equation}
\dot{x} = A_1 x + \varepsilon (Ax + \psi(x_1)b).
\end{equation}

Theorems 3 and 4 are proved in section 5.

Note the difference between the matrices $A_0$ and $A_1$, in the matrix $A_0$ the non-zero entries are only the odd numbers $1, 3, \ldots, 2n - 1$, while in the matrix $A_1$ the non-zero entries are the numbers $1, 2, \ldots, n$. This difference provides that the continuous and discontinuous piecewise linear differential systems (4) and (6) can have limit cycles detected by the averaging theory, while for the continuous and discontinuous piecewise linear differential systems (7) and (8) the averaging theory cannot detect limit cycles.

According to the results of the averaging theory used it follows that for the control differential systems here studied, the limit cycles that we obtain bifurcate from some periodic orbit of the $2n$-dimensional linear differential center (5). This technique of finding limit cycles bifurcating from centers has been intensively studied in dimension 2, see for instance the book of Christopher and Li [9] and the hundreds of references quoted therein.

Other results different to the ones presented here, but which also study the limit cycles of control systems of the form (1) using averaging theory, can be found in [6, 7, 8, 12, 14].
The main tools for proving the previous theorems are the extensions of the classical averaging theory for computing periodic solutions of $C^2$ differential systems to continuous and discontinuous differential systems. In section 2 we summarize the extensions of the averaging theory that we shall use here for proving our results.

2. First order averaging theory

For the classical averaging theory for finding periodic orbits of differential systems of class $C^2$ see for instance the chapter 11 of the book of Verhulst [17].

In this section we present first the result on the continuous averaging theory that we will use for proving our Theorems 1 and 3. This theory uses the Brouwer degree of a continuous function and its proof can be found in [5].

**Theorem 5.** We consider the following differential system

$$
\dot{x} = \varepsilon H(t, x) + \varepsilon^2 R(t, x, \varepsilon),
$$

where $H : \mathbb{R} \times D \to \mathbb{R}^n$, $R : \mathbb{R} \times D \times (-\varepsilon_f, \varepsilon_f) \to \mathbb{R}^n$ are continuous functions, $T$-periodic in the first variable, and $D$ is an open bounded subset of $\mathbb{R}^n$. We define $h : D \to \mathbb{R}^n$ as

$$
h(z) = \int_0^T H(s, z) ds,
$$

and assume that

(i) $H$ and $R$ are locally Lipschitz with respect to $x$;

(ii) for $p \in D$ with $h(p) = 0$, there exists a neighborhood $V$ of $p$ such that $h(z) \neq 0$ for all $z \in \overline{V} \setminus \{p\}$ and the Brouwer degree $d_B(h, V, 0) \neq 0$.

Then, for $|\varepsilon| \neq 0$ sufficiently small, there exists an isolated $T$-periodic solution $x(t, \varepsilon)$ of system (9) such that $x(0, \varepsilon) \to p$ as $\varepsilon \to 0$.

**Remark 6.** Let $h : D \to \mathbb{R}^n$ be a $C^1$ function with $h(p) = 0$, where $D$ is an open bounded subset of $\mathbb{R}^n$ and $p \in D$. If the Jacobian of $h$ at $p$ is not zero, then there exists a neighborhood $V$ of $p$ such that $h(z) \neq 0$ for all $z \in \overline{V} \setminus \{p\}$, and the Brouwer degree $d_B(h, V, p) \in \{-1, 1\}$.

For a proof of Remark 6 see for instance [15].

For proving Theorems 2 and 4 we shall need the following extension of the averaging theory for computing periodic solutions to discontinuous differential systems done in [13].

**Theorem 7.** We consider the following discontinuous differential system

$$
x'(t) = \varepsilon H(t, x) + \varepsilon^2 R(t, x, \varepsilon),
$$

with

$$
H(t, x) = H_1(t, x) + \text{sign}(g(t, x))H_2(t, x),
$$

$$
R(t, x, \varepsilon) = R_1(t, x, \varepsilon) + \text{sign}(g(t, x))R_2(t, x, \varepsilon),
$$
where $H_1, H_2 : \mathbb{R} \times D \rightarrow \mathbb{R}^n$, $R_1, R_2 : \mathbb{R} \times D \times (-\varepsilon_0, \varepsilon_0) \rightarrow \mathbb{R}^n$ and $g : \mathbb{R} \times D \rightarrow \mathbb{R}$ are continuous functions, $T$–periodic in the variable $t$ and $D$ is an open subset of $\mathbb{R}^n$. We also suppose that $g$ is a $C^1$ function having 0 as a regular value.

Define the average function $h : D \rightarrow \mathbb{R}^n$ as

$$h(x) = \int_0^T H(t, x)dt.$$  

We assume the following conditions.

(i) $H_1, H_2, R_1, R_2$ are locally Lipschitz with respect to $x$;

(ii) there exists an open bounded subset $C \subset D$ such that, for $|\varepsilon| > 0$ sufficiently small, every orbit starting in $C$ reaches the set of discontinuity only at its crossing regions.

(iii) for $a \in C$ with $h(a) = 0$, there exists a neighbourhood $U \subset C$ of $a$ such that $h(z) \neq 0$ for all $z \in U \setminus \{a\}$ and $dB(h, U, 0) \neq 0$.

Then, for $|\varepsilon| > 0$ sufficiently small, there exists a $T$–periodic solution $x(t, \varepsilon)$ of system (11) such that $x(0, \varepsilon) \to a$ as $\varepsilon \to 0$.

3. Proof of Theorem 1

The main tool for proving Theorem 1 is the averaging theory of first order for continuous differential systems presented in Theorem 5. In order to use this theorem we need to write the differential system (4) in the normal form (9), and for obtaining this we need to some changes of variables.

Lemma 8. Doing the change of variables $(x_1, x_2, \ldots, x_{2n}) \rightarrow (\theta, r, \theta_1, r_1, \ldots, \theta_{n-1}, r_{n-1})$ defined by

$$x_1 = r \cos \theta,$$
$$x_2 = r \sin \theta,$$
$$x_{2j-1} = r_{j-1} \cos((2j-1)\theta + \theta_{j-1}),$$
$$x_{2j} = r_{j-1} \sin((2j-1)\theta + \theta_{j-1}),$$

for $j = 2, \ldots, n$ system (4) is transformed into the system

$$\frac{dr}{d\theta} = \varepsilon H_1(\theta, r, \theta_1, \ldots, \theta_{n-1}, r_{n-1}) + O(\varepsilon^2),$$
$$\frac{dr_{j-1}}{d\theta} = \varepsilon H_{2(j-1)}(\theta, r, \theta_1, \ldots, \theta_{n-1}, r_{n-1}) + O(\varepsilon^2),$$
$$\frac{d\theta_{j-1}}{d\theta} = \varepsilon H_{2j-1}(\theta, r, \theta_1, \ldots, \theta_{n-1}, r_{n-1}) + O(\varepsilon^2),$$

where

$$H_1 = \sum_{l=1}^{n} r_{l-1} \left( F_{1,l} \cos \theta + F_{2,l} \sin \theta \right) + \varphi(r \cos \theta)(b_1 \cos \theta + b_2 \sin \theta),$$
and for \( j = 2, 3, \ldots, n \) we have

\[
H_{2(j-1)} = \sum_{l=1}^{n} r_{l-1} \left( F_{2j-1,l} \cos((2j-1)\theta + \theta_{j-1}) + F_{2j,l} \sin((2j-1)\theta + \theta_{j-1}) \right) \\
+ \varphi(r \cos \theta) [b_{2j-1} \cos((2j-1)\theta + \theta_{j-1}) + b_{2j} \sin((2j-1)\theta + \theta_{j-1})],
\]

\[
H_{2j-1} = \sum_{l=1}^{n} \frac{r_{l-1}}{r_{j-1}} \left( F_{2j,l} \cos((2j-1)\theta + \theta_{j-1}) - F_{2j-1,l} \sin((2j-1)\theta + \theta_{j-1}) \right) \\
+ (2j-1) \sum_{l=1}^{n} \frac{r_{l-1}}{r} \left( F_{1,l} \sin \theta - F_{2,l} \cos \theta \right) \\
+ \varphi(r \cos \theta) \left( \frac{b_{2j}}{r_{j-1}} \cos((2j-1)\theta + \theta_{j-1}) - \frac{b_{2j-1}}{r_{j-1}} \sin((2j-1)\theta + \theta_{j-1}) \right) \\
- (2j-1) \varphi(r \cos \theta) \left( \frac{b_{1}}{r} \cos \theta - \frac{b_{1}}{r} \sin \theta \right),
\]

with

\[
F_{i,l} = F_{i,l}(r, \theta, \theta_{l-1}) = a_{i(2l-1)} \cos((2l-1)\theta + \theta_{l-1}) + a_{i(2l)} \sin((2l-1)\theta + \theta_{l-1}).
\]

We take \( \varepsilon_0 \) sufficiently small, \( m \) arbitrarily large and

\[
D_m = \left\{ (r, \theta_1, r_1, \ldots, \theta_{n-1}, r_{n-1}) \in \left( \frac{1}{m}, m \right) \times \left[ \mathbb{S}^1 \times \left( \frac{1}{m}, m \right) \right]^{n-1} \right\}.
\]

Then the vector field of system \((13)\) is well defined and continuous on \( \mathbb{S}^1 \times D_m \times (-\varepsilon_0, \varepsilon_0) \). Moreover the system is \( 2\pi \)-periodic with respect to variable \( \theta \) and locally Lipschitz with respect to variables \((r, \theta_1, r_1, \ldots, \theta_{n-1}, r_{n-1})\).

Proof. In the variables \((\theta, r, \theta_1, r_1, \ldots, \theta_{n-1}, r_{n-1})\) the differential system \((4)\) becomes

\[
\dot{\theta} = 1 + \frac{\varepsilon}{r} \left[ \sum_{l=1}^{n} r_{l-1} \left( F_{2,l} \cos \theta - F_{1,l} \sin \theta \right) + \varphi(r \cos \theta)(b_2 \cos \theta - b_1 \sin \theta) \right],
\]

\[
\dot{r} = \varepsilon H_1(\theta, r, \theta_1, r_1, \ldots, \theta_{n-1}, r_{n-1}),
\]

\[
\dot{\theta}_{j-1} = \varepsilon H_{2(j-1)}(\theta, r, \theta_1, r_1, \ldots, \theta_{n-1}, r_{n-1}),
\]

\[
\dot{\theta}_{j-1} = \varepsilon H_{2j-1}(\theta, r, \theta_1, r_1, \ldots, \theta_{n-1}, r_{n-1}),
\]

for \( j = 2, 3, \ldots, n \). Note that for \( \varepsilon = 0 \), \( \dot{\theta}(t) > 0 \) and hence for \( |\varepsilon| \neq 0 \) sufficiently small this property remains valid for each \( t \) when \((\theta, r, \theta_1, r_1, \ldots, \theta_{n-1}, r_{n-1}) \in \mathbb{S}^1 \times D_m \). Now we take \( \theta \) as the new independent variable. The right-hand side of the new system is well defined and continuous in \( \mathbb{S}^1 \times D_m \times (-\varepsilon_0, \varepsilon_0) \) and it is \( 2\pi \)-periodic with respect to the new variable \( \theta \) and locally Lipschitz with respect to \((r, \theta_1, r_1, \ldots, \theta_{n-1}, r_{n-1})\). Now system \((8)\) can be obtained doing a Taylor series expansion in the parameter \( \varepsilon \) around \( \varepsilon = 0 \). \( \square \)
The next step is to find the corresponding average function (10) of system (8) that we denoted by \( h = (h_1, h_2, \ldots, h_{2(n-1)}, h_{2n-1}) : D_m \rightarrow \mathbb{R}^{n-1} \) and it is defined by

\[
\begin{align*}
    h_1 &= h_1(r, \theta_1, r_1, \ldots, \theta_{n-1}, r_{n-1}) = \int_0^{2\pi} H_1(r, \theta_1, r_1, \ldots, \theta_{n-1}, r_{n-1}) d\theta, \\
    h_{2(j-1)} &= h_{2(j-1)}(r, \theta_1, r_1, \ldots, \theta_{n-1}, r_{n-1}) = \int_0^{2\pi} H_{2(j-1)}(r, \theta_1, r_1, \ldots, \theta_{n-1}, r_{n-1}) d\theta, \\
    h_{2j-1} &= h_{2j-1}(r, \theta_1, r_1, \ldots, \theta_{n-1}, r_{n-1}) = \int_0^{2\pi} H_{2j-1}(r, \theta_1, r_1, \ldots, \theta_{n-1}, r_{n-1}) d\theta,
\end{align*}
\]

for \( j = 1, 2, \ldots, n \). To calculate these integrals we will use the following equalities

\[
\begin{align*}
    \int_0^{2\pi} \cos((2j-1)\theta + \theta_{j-1}) \sin((2l-1)\theta + \theta_{l-1}) d\theta &= 0 \quad \text{for all integers } l, j > 1, \\
    \int_0^{2\pi} \cos((2j-1)\theta + \theta_{j-1}) \cos((2l-1)\theta + \theta_{l-1}) d\theta &= \begin{cases} \pi & \text{if } l = j, \\
    0 & \text{if } l \neq j, \end{cases} \\
    \int_0^{2\pi} \sin((2j-1)\theta + \theta_{j-1}) \sin((2l-1)\theta + \theta_{l-1}) d\theta &= \begin{cases} \pi & \text{if } l = j, \\
    0 & \text{if } l \neq j, \end{cases}
\end{align*}
\]

and the next lemma.

For \( r > 0 \) and \( j = 1, 2, \ldots, n \) we denote

\[
\begin{align*}
    I_j(r) &= \int_0^{2\pi} \varphi(r \cos \theta) \cos((2j-1)\theta) d\theta, \\
    J_j(r) &= \int_0^{2\pi} \varphi(r \cos \theta) \sin((2j-1)\theta) d\theta,
\end{align*}
\]

where \( \varphi \) is the piecewise linear function (2).

**Lemma 9.** The integrals \( I_j \) and \( J_j(r) \) satisfy

\[
I_j(r) = \begin{cases} 
\pi r & \text{if } j = 1 \text{ and } 0 < r \leq 1, \\
0 & \text{if } j > 1 \text{ and } 0 < r \leq 1, \\
K(r) & \text{if } j = 1 \text{ and } r > 1, \\
L_j(r) & \text{if } j > 1 \text{ and } r > 1;
\end{cases}
\]

\[
J_j(r) = 0 \quad \text{for all } j = 1, 2, \ldots, n \text{ and } r > 0.
\]

where

\[
L_j(r) = \frac{2}{j(2j-1)^2} \left( (2j-1)\sqrt{-1 + r^2} \cos((2j-1) \arctan \sqrt{-1 + r^2}) \\
- \sin((2j-1) \arctan \sqrt{-1 + r^2}) \right),
\]

\[
K(r) = \pi r + \frac{2}{r} \sqrt{r^2 - 1} - 2r \arctan(\sqrt{r^2 - 1}).
\]
Proof. We consider two cases: $0 < r \leq 1$ and $r > 1$.

**Case 1:** $0 < r \leq 1$ In this case $|r \cos \theta| \leq 1$ and hence $\varphi(r \cos \theta) = r \cos \theta$ for all $\theta \in [0, 2\pi]$. Then if $j = 1$

$$\int_0^{2\pi} \varphi(r \cos \theta) \cos \theta d\theta = r \int_0^{2\pi} \cos^2 \theta d\theta = \pi r,$$

and

$$\int_0^{2\pi} \varphi(r \cos \theta) \sin \theta d\theta = r \int_0^{2\pi} \cos \theta \sin \theta d\theta = 0.$$

And if $j > 1$ then

$$\int_0^{2\pi} \varphi(r \cos \theta) \cos((2j-1)\theta) d\theta = r \int_0^{2\pi} \cos \theta \cos((2j-1)\theta) d\theta = 0,$$

$$\int_0^{2\pi} \varphi(r \cos \theta) \sin((2j-1)\theta) d\theta = r \int_0^{2\pi} \cos \theta \sin((2j-1)\theta) d\theta = 0.$$

**Case 2:** $r > 1$ In this case choose $\theta_c \in (0, \pi/2)$ such that $\cos \theta_c = 1/r$. If $j = 1$ we have

$$I_1(r) = \int_0^{\theta_c} \cos \theta d\theta + r \int_{\theta_c}^{\pi-\theta_c} \cos^2 \theta d\theta - \int_{\pi-\theta_c}^{\pi+\theta_c} \cos \theta d\theta + r \int_{\pi+\theta_c}^{2\pi-\theta_c} \cos^2 \theta d\theta \bigg|_{\pi-\theta_c}^{\pi+\theta_c} + r \int_{2\pi-\theta_c}^{2\pi} \cos \theta d\theta$$

$$= \pi r + \frac{2}{r} \sqrt{r^2 - 1} - 2r \arctan(\sqrt{r^2 - 1}).$$

The same reasoning can be applied to see that $J_1(r) = 0$. If $j > 1$ then

$$I_j(r) = \int_0^{\theta_c} \cos((2j-1)\theta) d\theta + r \int_{\theta_c}^{\pi-\theta_c} \cos \theta \cos((2j-1)\theta) d\theta - \int_{\pi-\theta_c}^{\pi+\theta_c} \cos \theta \cos((2j-1)\theta) d\theta + r \int_{\pi+\theta_c}^{2\pi-\theta_c} \cos \theta \cos((2j-1)\theta) d\theta$$

$$+ r \int_{2\pi-\theta_c}^{2\pi} \cos \theta \cos((2j-1)\theta) d\theta \bigg|_{\pi-\theta_c}^{\pi+\theta_c} + r \int_{2\pi-\theta_c}^{2\pi} \cos \theta \cos((2j-1)\theta) d\theta$$

$$= \frac{2}{j(2j-1)^2} \left( (2j-1) \sqrt{-1 + r^2} \cos((2j-1) \arctan \sqrt{-1 + r^2}) - \sin((2j-1) \arctan \sqrt{-1 + r^2}) \right),$$

and $J_j(r) = 0$. \qed

With the results presented previously we are able to prove Theorem 1. Since we can choose $m$ sufficiently large to find the zeroes of the average function $h$ in $D_m$ it is sufficient to look for them in $(0, \infty) \times [S^1 \times (0, \infty)]^{n-1}$. To calculate the expression of the average function we consider again two cases.
Case 1: $0 < r \leq 1$. In this case the system whose zeros can provide limit cycles of system (14) is

$$
\begin{align*}
    h_1 &= (a_{11} + a_{22} + b_1)\pi r, \\
    h_2 &= (a_{33} + a_{44})\pi r_1, \\
    h_3 &= (a_{43} - a_{34} + 3(a_{12} - a_{21} - b_2))\pi, \\
    &\vdots \\
    h_{2(n-1)} &= (a(2n-1)(2n-1) + a(2n)(2n))\pi r_{n-1}, \\
    h_{2n-1} &= (a(2n)(2n-1) - a(2n-1)(2n) + (2n - 1)(a_{12} - a_{21} - b_2)\pi.
\end{align*}
$$

Note that the variables $\theta_1, \theta_2, \ldots, \theta_{n-1}$ does not appear explicitly into system (14). Hence, if this system has zeros, it has a continuum of zeros. Therefore the assumption (ii) of the averaging theory, presented in Theorem 5, is not satisfied and this theorem does not provide any information about the limit cycles of system (13).

Case 2: $r > 1$. Now the system whose zeros can provide limit cycles of system (13) is

$$
\begin{align*}
    h_1 &= (a_{11} + a_{22})\pi r + b_1 K(r), \\
    h_2 &= (a_{33} + a_{44})\pi r_1 + (b_3 \cos \theta_1 + b_4 \sin \theta_2)L_2(r), \\
    h_3 &= (a_{43} - a_{34} + 3(a_{12} - a_{21}))\pi - \\
    &\frac{3b_2 r_1 K(r) - r(b_4 \cos \theta_1 - b_3 \sin \theta_1)L_2(r)}{r r_1}, \\
    &\vdots \\
    h_{2(n-1)} &= (a(2n-1)(2n-1) + a(2n)(2n))\pi r_{n-1} + \\
    &\left(b_{2n-1} \cos \theta_{n-1} + b_{2n} \sin \theta_{n-1}\right)L_n(r), \\
    h_{2n-1} &= (a(2n)(2n-1) - a(2n-1)(2n) + (2n - 1)(a_{12} - a_{21}))\pi - \\
    &\frac{(2n - 1)b_2 r_{n-1} K(r) - r(b_{2n} \cos \theta_{n-1} - b_{2n-1} \sin \theta_{n-1})L_n(r)}{r r_{n-1}},
\end{align*}
$$
For each \( j \in \{2, 3, \ldots, n\} \) we will study the zeros of the system

\[
h_1 = (a_{11} + a_{22}) \pi r + b_1 K(r),
\]

\[
h_{2(j-1)} = (a_{(2j-1)(2j-1)} + a_{(2j)(2j)}) \pi r_{j-1} + (b_{2j-1} \cos \theta_{j-1} + b_{2j} \sin \theta_{j-1}) L_j(r),
\]

\[
h_{2j-1} = (a_{(2j)(2j-1)} - a_{(2j-1)(2j)} + (2j - 1)(a_{12} - a_{21})) \pi - \frac{(2j - 1)b_{2j} r_{j-1} K(r) - r(b_{2j} \cos \theta_{j-1} - b_{2j-1} \sin \theta_{j-1}) L_j(r)}{r r_{j-1}},
\]

**Claim:** The function \( K : (1, \infty) \to (\pi, 4) \) is a diffeomorphism. Indeed note that \( K \) is twice differentiable with

\[
K'(r) = \pi - 2\sqrt{r^2 - 1} - 2 \arctan \sqrt{r^2 - 1},
\]

and

\[
K''(r) = -4 \frac{3}{r^3 \sqrt{r^2 - 1}} < 0
\]

which implies that \( K' \) is a strictly decreasing function. Moreover \( \lim_{r \to \infty} K'(r) = 0 \) what means that \( K'(r) \) has a horizontal asymptote given by the axis \( r \) and then \( K'(r) \geq 0 \). Suppose that there exists an \( r_0 \in (1, \infty) \) such that \( K'(r_0) = 0 \). Then for all \( r > r_0 \) we have \( K'(r) < K'(r_0) = 0 \), contradiction. Therefore it follows that \( K'(r) \neq 0 \) for all \( r \in (1, \infty) \) and the Inverse Function Theorem guarantees that \( K \) is a local diffeomorphism and since that \( K \) is a injective function we obtain the global diffeomorphism, ending the proof of this claim.

First we note that in order that the equation \( h_1 = 0 \) has solutions with \( r > 1 \) it is necessary that \( b_1 (a_{11} + a_{22}) < 0 \). Moreover \( K''(r) < 0 \) implies that the graph of \( K \) is convex. In the plane of the graph of \( K(r) \) the graph of \( (a_{11} + a_{22}) \pi r \) is a straight line passing through the origin and then both graphs can intersect at most in two points.

**Figure 1.** The graphic of the function \( K(r) \).
But if some straight line intercept the graph of $K(r)$ in two points then it cannot pass through the origin, as we can see in Figure 1. Then the equation $h_1 = 0$ has at most one solution if $r > 1$, and since that $K(r)$ is a diffeomorphism we can choose the coefficients $a_{11}, a_{22}$ and $b_1$ so that this solution exists. We denote this solution by $r_0$ and we substitute it into the equations $h_{2(j-1)} = 0$ and $h_{2j-1} = 0$. Defining

$$A_j = (a_{(2j-1)(2j-1)} + a_{(2j)(2j)}) \pi, \quad B_j = b_{2j-1}L_j(r_0), \quad C_j = b_{2j}L_j(r_0),$$

$$D_j = (a_{(2j)(2j-1)} - a_{(2j-1)(2j)} + (2j - 1)(a_{12} - a_{21})) \pi - \frac{1}{r_0} (2j - 1)b_2K(r_0),$$

$$u_j = \cos \theta_{j-1}, \quad v_j = \sin \theta_{j-1},$$

the system $h_{2(j-1)} = h_{2j-1} = 0$ is equivalent to the system

$$A_j r_{j-1} + B_j u_j + C_j v_j = 0,$$

$$D_j r_{j-1} + C_j u_j - B_j v_j = 0,$$

$$u_j^2 + v_j^2 - 1 = 0.$$

Using the two first equations we obtain

$$u_j = -\frac{(A_j B_j + C_j D_j)r_{j-1}}{B_j^2 + C_j^2}, \quad v_j = \frac{(B_j D_j - A_j C_j)r_{j-1}}{B_j^2 + C_j^2}.$$

Substituting these two expressions in the third equation we get

$$(A_j^2 + D_j^2)r_{j-1}^2 - B_j^2 - C_j^2 = 0.$$

Therefore at most there is one solution $r_{j-1} > 0$, which provide a unique $u_j$ and $v_j$. Since we fixed an arbitrarily $j$ to solve this system, the same reasoning can be applied to each pair of equations $h_{2(j-1)} = 0$ and $h_{2j-1} = 0$, concluding that system (15) has at most one solution. Moreover taking conveniently the parameters of the initial system (4) this solution exists and its Jacobian is not zero. Hence at most one limit cycle can bifurcate from the periodic orbits of the center of system (5) when we perturbe it as in system (4), and there are systems for which a such limit cycles exist. This completes the proof of Theorem 1.

Now we present an explicit example of a continuous piecewise linear differential system (4) in $\mathbb{R}^4$, and repeating for it the proof of Theorem 1 we will show it has one limit cycle. Consider the following differential system

$$(16) \quad \dot{x} = A_0x + \varepsilon(Ax + \varphi(x_1)b),$$
where

\[
\begin{pmatrix}
0 & -1 & 0 & 0 \\
1 & 0 & 0 & 0 \\
0 & 0 & 0 & -3 \\
0 & 0 & 3 & 0
\end{pmatrix}
\begin{pmatrix}
1 & 0 & 0 & 0 \\
2 & 0 & 0 & 0 \\
0 & 0 & -2 & -1 \\
0 & 0 & 0 & \frac{18\pi - \sqrt{3}}{9\pi}
\end{pmatrix}
\begin{pmatrix}
-\frac{24\pi}{3\sqrt{3} + 2\pi} \\
1 \\
\frac{9(3 - 2\sqrt{3}\pi)}{2} \\
-1
\end{pmatrix}.
\]

Doing the change of variables \( x_1 = r \cos \theta, \ x_2 = r \sin \theta, \ x_3 = r_1 \cos(3\theta + \theta_1), \ x_4 = r_1 \sin(3\theta + \theta_1) \) and taking \( \theta \) as the new independent variable we obtain the system (17)

\[
\begin{align*}
\frac{dr}{d\theta} &= \epsilon H_1(\theta, r, \theta_1, r_1) + O(\epsilon^2), \\
\frac{dr_1}{d\theta} &= \epsilon H_2(\theta, r, \theta_1, r_1) + O(\epsilon^2), \\
\frac{d\theta_1}{d\theta} &= \epsilon H_3(\theta, r, \theta_1, r_1) + O(\epsilon^2), \\
H_1(\theta, r, \theta_1, r_1) &= 2r + \varphi(r \cos \theta) \sin \theta + \cos \theta \left( r \sin \theta - \frac{24\pi \varphi(r \cos \theta)}{3\sqrt{3} + 2\pi} \right), \\
H_2(\theta, r, \theta_1, r_1) &= -\frac{1}{18\pi} \left( 18\pi \varphi(r \cos \theta) \sin(3\theta + \theta_1) + 9\pi r_1 \sin(2(3\theta + \theta_1)) \\
&\quad + \sqrt{3}r_1 + 81\pi(2\sqrt{3}\pi - 3) \varphi(r \cos \theta) \cos(3\theta + \theta_1) - (\sqrt{3} - 36\pi)r_1 \cos(2(3\theta + \theta_1)) \right), \\
H_3(\theta, r, \theta_1, r_1) &= \sin^2(3\theta + \theta_1) + 2\sin(2(3\theta + \theta_1)) - \frac{\sin(2(3\theta + \theta_1))}{6\sqrt{3}\pi} + 3\sin^2 \theta \\
&\quad - \frac{72\pi \varphi(r \cos \theta) \sin \theta}{3\sqrt{3}r + 2\pi r} - \frac{\varphi(r \cos \theta) \cos(3\theta + \theta_1)}{r_1} - \frac{3\varphi(r \cos \theta) \cos \theta}{r_1} \\
&\quad + \frac{r_1}{9\pi \sqrt{3} \varphi(r \cos \theta) \sin(3\theta + \theta_1) - 27\varphi(r \cos \theta) \sin(3\theta + \theta_1)}.
\end{align*}
\]

After some computations the average function \( h = (h_1, h_2, h_3) \) defined in (10) is

\[
\begin{align*}
h_1(r, \theta_1, r_1) &= 4\pi r - \frac{24\pi}{3\sqrt{3} + 2\pi} \left( \pi r + \frac{2\sqrt{r^2 - 1}}{r} - 2r \arctan(\sqrt{r^2 - 1}) \right), \\
h_2(r, \theta_1, r_1) &= \frac{\sqrt{3}}{3} \sin \theta_1 + \frac{3}{2} (2\sqrt{3}\pi - 3) \sqrt{3} \cos \theta_1 - \frac{\sqrt{3}}{9} r_1, \\
h_3(r, \theta_1, r_1) &= \frac{9\sqrt{3} \sin \theta_1}{2r_1} - \frac{9\pi \sin \theta_1}{r_1} + \frac{\sqrt{3} \cos \theta_1}{3r_1} - \frac{3}{2} \left( \sqrt{3} + \frac{2\pi}{3} \right) + 4\pi.
\end{align*}
\]
In order to solve the system \( h_1 = h_2 = h_3 = 0 \) we can use the same reasoning applied in the proof of Theorem 1 obtaining that \((r^*, \theta^*_1, r^*_1) = (2, \pi/2, 3)\) is a zero of the average function. Moreover if \( J = J(r, \theta_1, r_1) \) is the Jacobian matrix of \( h \), then \( \det J(2, \pi/2, 3) \neq 0 \) which implies that we have a simple zero. By Theorem 5 system (17) and consequently system (16) has one limit cycle for \(|\varepsilon| > 0\) sufficiently small.

4. Proof of Theorem 2

This section is devoted to prove Theorem 2. According to Theorem 7 the same kind of arguments used for proving Theorem 1 can be applied to the discontinuous system (6), obtaining that the average function \( h = (h_1, h_2, \ldots, h_{2(n-1)}, h_{2n-1}) : D_m \to \mathbb{R}^{n-1} \) defined in (12) is

\[
\begin{align*}
  h_1 &= (a_{11} + a_{22}) \pi r + b_1 \bar{I}_1, \\
  h_{2(j-1)} &= (a_{(2j-1)(2j-1)} + a_{(2j)(2j)}) \pi r_{j-1} + (b_{2j-1} \cos \theta_{j-1} + b_{2j} \sin \theta_{j-1}) \bar{J}_j, \\
  h_{2j-1} &= (a_{(2j)(2j)} - a_{(2j-1)(2j)}) + (2j - 1)(a_{12} - a_{21}) \pi - \\
  &\quad (2j - 1) b_{2j} r_{j-1} \bar{I}_1 - r (b_{2j} \cos \theta_{j-1} - b_{2j-1} \sin \theta_{j-1}) \bar{J}_j, \\
  
\end{align*}
\]

for \( j = 2, 3, \ldots, n \), where

\[
\bar{I}_j = \begin{cases} 
  -4 & \text{if } j \text{ is even,} \\
  4 & \text{if } j \text{ is odd.}
\end{cases}
\]

In fact if we define

\[
\bar{I}_j = \int_0^{2\pi} \psi(r \cos \theta) \cos((2j - 1)\theta) d\theta, \\
\bar{J}_j = \int_0^{2\pi} \psi(r \cos \theta) \sin((2j - 1)\theta) d\theta,
\]

where \( \psi \) is the piecewise linear function given by (3). Then we have that

\[
\bar{I}_j = \int_0^{2\pi} \psi(r \cos \theta) \cos((2j - 1)\theta) d\theta \\
= \int_0^{\pi/2} \cos((2j - 1)\theta) d\theta - \int_{\pi/2}^{3\pi/2} \cos((2j - 1)\theta) d\theta + \int_{3\pi/2}^{2\pi} \cos((2j - 1)\theta) d\theta \\
= -\frac{4}{(2j - 1)} \cos(j\pi),
\]
and
\[
\bar{J}_j = \int_0^{2\pi} \psi(r \cos \theta) \sin((2j - 1)\theta) d\theta \\
= \int_0^{\pi/2} \sin((2j - 1)\theta) d\theta - \int_{\pi/2}^{3\pi/2} \sin((2j - 1)\theta) d\theta + \int_0^{2\pi} \sin((2j - 1)\theta) d\theta \\
= -\frac{4}{(2j - 1)} \sin(j\pi) \cos(j\pi) = 0.
\]

Note that \(\bar{I}_j\) is a constant real number different from zero, and hence \(h_1\) is a straight line, and then system (18) has at most one positive zero. Moreover if we choose conveniently the coefficients \(b_1 a_{11}\) and \(a_{22}\) we can find a simple positive zero of system (18). This completes the proof of Theorem 2.

5. **Proof of Theorems 3 and 4**

Doing the change of coordinates
\[
x_1 = r \cos \theta, \quad x_2 = r \sin \theta,
\]
\[
x_{2j-1} = r_{j-1} \cos(j\theta + \theta_{j-1}), \quad x_{2j} = r_{j-1} \sin(j\theta + \theta_{j-1}) \quad j \in \{2, 3, \ldots, n\},
\]
for \(j = 2, 3, \ldots, n\), to the continuous piecewise linear differential system (7), and working as in the proof of Theorem 1 we obtain that the average function \(h = (h_1, h_2, \ldots, h_{2n-1})\) defined in (10) now is given by
\[
h_1 = (a_{11} + a_{22}) \pi r + b_1 I_1(r),
\]
\[
h_{2(j-1)} = (a_{(2j-1)(2j-1)} + a_{(2j)(2j)}) \pi r_{j-1} + \left( b_{2j-1} \cos \theta_{j-1} + b_{2j} \sin \theta_{j-1} \right) I_j(r),
\]
\[
h_{2j-1} = \left( a_{(2j)(2j-1)} - a_{(2j-1)(2j)} + j(a_{12} - a_{21}) \right) \pi - \frac{jb_2 r_{j-1} I_1(r) - r (b_{2j} \cos \theta_{j-1} - b_{2j-1} \sin \theta_{j-1}) I_j(r)}{rr_{j-1}},
\]
where
\[
I_j(r) = \int_0^{2\pi} \varphi(r \cos \theta) \cos(j\theta) d\theta.
\]

Using exactly the same arguments than in the proof of Lemma 9 is possible to prove that
\[
I_j(r) = \begin{cases} 
\pi r & \text{if } j = 1 \text{ and } 0 < r \leq 1, \\
0 & \text{if } j \text{ is even and } 0 < r \leq 1, \\
L_j(r) & \text{if } j \text{ is odd and } r > 1,
\end{cases}
\]
where
\[
L_j(r) = \frac{4}{j^2 - 1} \left( j \sqrt{r^2 - 1} \cos(j \arctan(\sqrt{r^2 - 1})) - \sin(j \arctan(\sqrt{r^2 - 1})) \right).
\]
The simple zeros of system (19) provide the existence of limit cycles for system (7) but since \( I_j(r) = 0 \) if \( j \) is even and \( r > 1 \), the variables \( \theta_{j-1} \), for \( j = 2, 4, 6, \ldots \) do not appear in the system \( h_1 = h_2 = \ldots = h_{2n-1} = 0 \), so either this system has no zeros, or if it has zeros, then it has a continuum of zeros, and therefore the assumption (ii) of the averaging Theorem 9 does not hold, and consequently the averaging theory cannot say anything about the limit cycles of system (7). The same occurs for the case \( 0 < r \leq 1 \). So we conclude that, using the averaging theory of first order, we can say nothing about the number of the limit cycles of system (7). This completes the proof of Theorems 3.

Now if we consider the discontinuous piecewise linear differential system (8), then its average function \( h = (h_1, h_2, \ldots, h_{2n-1}) \) defined in (12) is

\[
h_1 = (a_{11} + a_{22})\pi r + b_1 I_1, \\
h_{2j-1} = (a_{(2j-1)(2j-1)} + a_{(2j)(2j)})\pi r_{j-1} + (b_{2j-1} \cos \theta_{j-1} + b_{2j} \sin \theta_{j-1}) I_j, \\
h_{2j} = (a_{(2j)(2j-1)} - a_{(2j-1)(2j)} + j(a_{12} - a_{21}))\pi - j b_{2j} r_{j-1} I_1 - r (b_{2j} \cos \theta_{j-1} - b_{2j-1} \sin \theta_{j-1}) I_j, \\
\]

where

\[
I_j = \int_0^{2\pi} \psi(r \cos \theta) \cos(j\theta) d\theta.
\]

Again we have that

\[
I_j = \int_0^{2\pi} \psi(r \cos \theta) \cos(j\theta) d\theta = \begin{cases} 
0 & \text{if } j \text{ is even,} \\
\pm \frac{4}{(2j-1)} & \text{if } j \text{ is odd,} 
\end{cases}
\]

and we can see that again either no zeros of the function \( h \), or a continuum of zeros, concluding that the averaging theory of first order given by Theorem 7 does not say anything about the limit cycles of system (8). This completes the proof of Theorems 4.
