“Liver–gut” axis: A target of traditional Chinese medicine for the treatment of non-alcoholic fatty liver disease

Kangxiao Guo, Sisheng Xu and Zhaofeng Zeng*

Changsha Health Vocational College, Changsha, Hunan, China

Non-alcoholic fatty liver disease (NAFLD) occurs when fat accumulates in the liver even without excessive alcohol intake. Among the current therapeutic approaches for NAFLD, lifestyle modification with dietary changes and regular exercise is the mainstay treatment. With the rise of intestinal microecology, regulation of the “liver–gut” axis can be an effective treatment for NAFLD. This review aimed to assess the modulation of the liver–gut microbiota axis with traditional Chinese medicine (TCM) as a therapeutic approach to NAFLD and further explored its application in the newly discovered therapeutic avenues beyond NAFLD treatment.

KEYWORDS
“liver–gut” axis, intestinal microorganisms, traditional Chinese medicine, NAFLD, target

Introduction

Non-alcoholic fatty liver disease (NAFLD) is a clinicopathological syndrome with liver histological changes similar to alcoholic liver disease, but without a history of excessive alcohol consumption, including non-alcoholic steatosis (non-alcoholic fatty liver, NAFL) without inflammation and non-alcoholic steatohepatitis (NASH), which is associated with hepatocyte death, inflammation, and fibrosis. NAFL causes NASH, which can further evolve into liver cirrhosis; however, NASH can also sometimes lead to other outcomes. Thirty percent of patients with NASH will develop liver cirrhosis within 5–10 years. Clinical studies have shown that NAFLD is related to diabetes, hypertension, insulin resistance, abnormal liver lipid metabolism, and other factors (1). At present, NAFLD is a global epidemic trend and is one of the reasons for the increase of liver cirrhosis and liver cancer, becoming the world’s largest chronic liver disease. In Western countries, especially the United States, NAFLD has become the second leading cause of liver transplantation. However, NAFLD is not endemic to Western countries. With the increasing industrialization in Asian countries, as well as changes in lifestyle and diet, the
prevalence of NAFLD in Asia has continued to increase. Li et al. (2) found that the overall prevalence of NAFLD in Asia was 29.62%. Japan had the lowest prevalence (22.28%), while Indonesia had the highest prevalence (51.04%); the general population of Mainland China had a prevalence of 29.81%. It is worth noting that the prevalence of NAFLD in Asia has been increasing year by year (25.28% in 1999–2005, 28.46% in 2006–2011, and 33.90% in 2012–2017). However, in Asia, there was no significant difference in the prevalence of NAFLD in countries with different income levels (high, upper-middle, and low), and there was no difference in the prevalence of NAFLD between rural and urban populations. Therefore, attention should also be paid to the harm caused by NAFLD in non-affluent areas, the low- and middle-income groups in Asia. In addition to its high prevalence, the harm caused by NAFLD is manifested in the fact that it can lead to liver lesions, including cirrhosis and liver cancer. At present, it is believed that NAFLD may have become another important cause of primary liver cancer after hepatitis B (HBV) and hepatitis C (HCV) virus. The annual incidence of primary liver cancer in the Asian population with NAFLD is 1.8‰, and the all-cause mortality rate is 5.3‰. The all-cause mortality of NAFLD patients can be as high as 7.3‰ (2).

Among the current treatment approaches for NAFLD, lifestyle modification with dietary changes and regular exercise is the mainstay (3), but the treatment effect is often not good and more adverse reactions are reported (4). Although promising therapeutic options targeting mechanisms for patients with NAFLD are available (5), particularly for NASH, none has been approved by the international medical community. Presently, a lot of studies have shown that Chinese medicine, relative to Western medicine, has multi-level and multi-target features, integrity, complex chemical composition, fewer adverse reactions, and a long history; therefore, a lot of scholars believe that the treatment of NAFLD using TCM has certain advantages, as long as clinical syndrome differentiation is correct, which often achieves good effects (6).

The human gut microbiota is a complex ecosystem that comprises a wide variety of bacteria, which total to approximately 1–2 kg in mass (7, 8). The gut microbiota maintains a close relationship with the host, with important roles in vitamin production, the mucosal immune system, and bacterial translocation (9). However, an overall understanding of the gut microbiota, including differences in their composition according to geographical regions, gender, and age, is yet to be established (10, 11). Theoretically, the modulation of the gut microbiota through the administration of antibiotics, probiotics, prebiotics, and symbiotics or through fecal microbiota transplantation (FMT) can be an effective approach to the treatment of NAFLD. Recent studies have released results that support this theory (12, 13).

This review aimed to assess the modulation of the liver–gut microbiota axis with traditional Chinese medicine (TCM) as a therapeutic approach for NAFLD and further explored its application in the newly discovered therapeutic avenues beyond NAFLD treatment.

The pathogenesis of NAFLD

NAFLD is a clinicopathological syndrome characterized by fatty degeneration of liver parenchymal cells caused by alcohol consumption and other liver damage factors (e.g., drug damage, viral infection, and autoimmunity, among others) (14). Comprehensive diagnosis is mainly made through laboratory and ultrasonographic examinations. The specific pathogenesis of NAFLD is presently still unclear. The “second hit” theory originated over the past decade has been widely recognized. The “first hit” is hepatic steatosis caused by insulin resistance (IR). IR refers to the decrease in the sensitivity of insulin-acting target organs to insulin; that is, a normal dose of insulin produces a fraction of the normal biological effect. This state leads to the accumulation of triacylglycerols in the liver and the decline of liver tolerance to internal and external injury factors, such as ischemia and hypoxia. In the second hit, under oxidative stress, inflammatory factors, and endotoxins, among other factors, the liver tissue shows inflammation, fibrosis, and other pathological changes, causing NASH (15). Evidence from the latest medical research has shown that the occurrence of NAFLD may also be related to poor dietary habits. A high-fat diet or large amounts of dietary fructose in the diet can cause IR and hyperleptinemia, which are accompanied by NAFLD (16). Inter-microecological imbalance is also one of the important causes of NAFLD (17). Imbalance in the intestinal flora causes damage to the intestinal mucosal barrier, increases the intestinal mucosal permeability, and induces overgrowth of some intestinal flora, including lipopolysaccharides (LPS), short-chain fatty acids (SCFAs), acetic acid, inflammatory inducers, and other harmful substances, through the intestinal barrier into the blood circulation and to the liver, thus activating the host immune system of cytokines and inflammatory mediators, forming an inflammatory response and affecting the liver (18).

Effect of the “liver–gut” axis on NAFLD

“Liver–gut” axis

In 1998, Marshall proposed the concept of the “liver–gut” axis. Since then, the relationship between the gut and the liver has been receiving more attention. Studies have confirmed that the liver–gut axis is an important part of the pathogenesis of NAFLD (5). Their common embryonic origin makes the liver and the intestine closely related in terms of anatomy and biological function, and they communicate through the bile duct, portal vein, systemic circulation, and tight bidirectional
connection. When the permeability of the intestinal mucosa increases, the barrier function is impaired. A lot of bacteria and endotoxins in the intestinal tract enter the portal vein system. Kupffer cells and hepatic stellate cells in the liver are activated by LPS, the main lipid components of the cell wall of Gram-negative bacteria, and the released inflammatory factors participate in the process of liver disease. These inflammatory factors can cause continuous damage to the liver, such as tumor necrosis factor alpha (TNF-α). Enterohepatic circulation is the communication system between the liver and the gut. Bile acids in the gut are recovered by the liver, secreted into the bile ducts, and then reabsorbed in the gut. Therefore, the balance of bile acids in the body determines the homeostasis of the liver–gut axis (19, 20). As important components in the gut, bile acids can inhibit the overgrowth of intestinal bacteria and affect the composition and quantity of the intestinal flora (21, 22).

"Liver–gut" axis in non-alcoholic fatty liver disease

The intestinal barrier mainly comprises an immune barrier, mechanical barrier, chemical barrier, and biological barrier (as shown in Figure 1). The biological barrier is mainly composed of intestinal microorganisms, and these intestinal microorganisms continuously form a complex and stable microbiome with the growth and development of the human body (23). The gut microbial ecosystem includes bacteria, fungi, and viruses, among others, which, together, play a role in food digestion, nutrient absorption, immune regulation, and tumor suppression, which are of great significance to maintaining the intestinal epithelial barrier function. Under the condition of stable balance, the intestinal microecology maintains the coordinated operation of the body’s organ functions. When the composition, quantity, metabolic activity, and the distribution of intestinal microbes change under different nutritional, immune, and environmental conditions, this will trigger the body’s chronic inflammatory response and even lead to a series of diseases (24).

In terms of anatomical structure and physiological function, the relationship between the liver and the intestine is inseparable. The nutrients absorbed in the intestine can be transported into the liver from the portal system through the blood, and the bile acids and other biologically active substances synthesized in the liver can also be secreted into the intestine for metabolism, thereby inhibiting the overgrowth of intestinal bacteria. When there is imbalance in the intestinal flora, the intestinal mucosal barrier is damaged and the permeability is increased. Bacteria, endotoxins, and metabolites enter the liver through the portal vein, resulting in impaired liver function; the liver then releases a series of inflammatory factors, which in turn cause intestinal damage (Figure 2). Yuan et al. (25) established a mouse model by strain colonization and FMT and found that Klebsiella pneumoniae, which produces a large amount of alcohol, can induce mitochondrial damage, impair the intestinal mucosal function, aggravate liver inflammation, and lead to the development of NAFLD. Another study compared the fecal flora of healthy groups and patients with NAFLD and observed changes in the diversity and composition of the flora, with increased proportion of Bacteroidetes and a decreased abundance of Firmicutes (26). In a study of the intestinal microbiota of 37 patients with NAFLD, Jasirwan et al. (27) found that Firmicutes, Bacteroidetes, and Proteobacteria were
the predominant phyla. Bacteroides was more dominant than Prevotella, contrary to the results of previous studies on healthy populations in Indonesia. Microbiota dysbiosis was observed in most of the samples. The diversity of the gastrointestinal microbiota was significantly decreased in patients with NAFLD, high triglyceride levels, and central obesity. The Firmicutes/Bacteroidetes ratio was correlated with steatosis and obesity, whereas some of the other species in the lower taxonomy levels were mostly associated with steatosis and obesity without fibrosis. Proteobacteria was the only phylum strongly correlated with fibrosis in patients with an average body mass index. Certain gut microorganisms were correlated with fibrosis and steatosis. Philips et al. (28) found that the gut microbiota has a significant impact on NAFLD. Their study performed fecal transplantation in eight patients with steroid-resistant alcoholic hepatitis. It was found that the overall survival of patients who received a fecal transplant was 87.5%, while that of patients who did not receive a fecal transplant was 33.3%. One year after transplantation, bowel deformation was observed. A decrease in Bacillus and an increase in Firmicutes were found. Studies have shown that Bifidobacterium and Lactobacillus strains may have different effects on NAFLD and that some Bifidobacterium species may have protective effects in the development of NAFLD, NASH, and obesity (29). The genus Bifidobacterium can be considered as one of the targets for NAFLD treatment using intestinal microbiome. Huang et al. fed Sprague–Dawley (SD) rats with a high-fat diet for 12 weeks to establish an NAFLD model. The study found that the liver tissue of NAFLD model rats was grayish yellow, with obvious fatty lesions, and increased cholesterol/lp-density lipoprotein (LDL) cholesterol ratio and alanine (30). The activity of alanine aminotransferase (ALT) in the NAFLD group was significantly higher than that in the normal group (p < 0.01). The DNA of the cecal mucosa was extracted, and 16S rDNA high-throughput Illumina sequencing was used to analyze the intestinal flora of NAFLD rats. The results showed that the alpha diversity indices of the normal group were all significantly higher than those of the NAFLD model group. In the comparisons at the bacterial phylum level, the ratio of Firmicutes/Bacteroidetes in the normal group was shown to be significantly higher than that in the NAFLD model group (p < 0.05), while the proportion of Verrucomicrobia in the NAFLD model group was significantly increased. Comparisons at the bacterial genus level revealed that the intestinal lactobacilli in the NAFLD model group were significantly lower than those in the normal group. This study showed that NAFLD rats developed dysbacteriosis and had a decreased number of beneficial intestinal bacteria. Some studies have also found that lipid metabolism disorders can induce an imbalance in the intestinal flora, which in turn can exacerbate lipid metabolism disorders, both of which are closely related to the occurrence and development of fatty liver (31). Ley et al. (32) found that two different diets resulted in intestinal microbiological changes related to obesity and IR. IR is an important feature of NAFLD, which can be improved by antibiotic treatment (33). However, intestinal symbiotic bacteria are also very important. The study found that the severity of experimental liver fibrosis in sterile mice worsened (34). After the mice were administered small doses of antibiotics, their intestinal microbiota changed and the contents of intestinal SCFAs and cholesterol significantly increased, thus changing the fatty acid and cholesterol

![FIGURE 2](image-url)
metabolism of the liver (35). Intestinal flora disorder can also directly affect the levels of fat factors, pro- and anti-inflammatory factors, and fat oxidation factors, thereby affecting liver metabolism and promoting liver damage (36).

Progress in TCM treatment of NAFLD based on the regulation of the “liver–gut” axis

Association between traditional Chinese medicine “liver and spleen theory” and “liver–gut” axis function

TCM believes that the liver belongs to wood and the spleen belongs to earth. The qi of the spleen can fill the qi and blood metaplasia and nourish the liver. Diseases of the liver transmit diseases to the spleen through the meridians, and damage in the spleen will affect the function of the liver (37). Emotional insufficiency blocks the qi movement, affecting the operation of the body’s qi, blood, and body fluids, and the liver qi stagnation accumulates for a long time. Liver stagnation and spleen deficiency are each other’s cause and effect. The transportation and transformation of the spleen depends on the normal function of the liver to disperse and relieve the spleen. Therefore, many doctors have advocated the treatment of NAFLD from the perspective of the liver and spleen, with regulation of the liver and spleen as the basic treatment method. Regulation of the liver also includes soothing it, promoting blood circulation, and promoting qi, while regulation of the spleen includes strengthening it, resolving phlegm and damp. The “Consensus on the diagnosis and treatment of non-alcoholic fatty liver diseases” pointed out that NAFLD is located in the liver and involves the spleen, stomach, and other organs. The main clinical symptoms of NAFLD include liver depression and spleen deficiency, damp-turbid internal stop, damp-heat accumulation, and phlegm and blood stasis syndrome, among others. During the development of the disease, spleen deficiency is the basic pathogenesis, as well as liver stagnation and spleen deficiency, phlegm turbidity, and internal accumulation of damp-heat, finally leading to a phlegm–damp–blood stasis inter-association. NAFLD is caused by fat deposits in the liver. Liver stagnation leads to spleen deficiency, and in the etiology and the pathological products of these syndromes, phlegm and dampness are produced by the lack of water dampness. In the final analysis, it is still a dysfunction of the spleen (38). The spleen transports and transforms water dampness. Deficiency of the spleen can lead to the lack of internal water dampness, which then leads to dampness accumulation into phlegm, and water dampness and phlegm-drinking block the normal operation of the blood. If there is luck on the side, with qi and blood circulation, this accumulation will disappear. This shows the importance of strengthening the spleen in the treatment of NAFLD.

From the perspective of modern medicine, the “spleen” in TCM theory performs the “gastrointestinal” function in the narrow sense of modern anatomy. In terms of function, the spleen, the small intestine, and the large intestine are related. The spleen is responsible for promoting clearness and transporting and transforming water and moisture, while the small intestine receives water and grains from the five internal organs and is also responsible for the secretion of clear turbidity. The large intestine, on the other hand, is responsible for conducting dregs and further absorbing body fluids. Research on the internal relationship between the “spleen and stomach–turbid poison” and the “intestinal bacteria–metabolic syndrome” has put forward the theory that, although the intestinal microecology is anatomically located in the intestine, its function belongs to the spleen (39). The liver–gut axis is proposed in modern medicine. It is believed that the intestinal barrier function is damaged, the intestinal bacteria are translocated, endotoxins enter the portal system, the immune mechanism in the liver is activated, and a large number of inflammatory factors are released, thereby causing injury in the intestinal mucosa and other organs. It can be seen through the liver–gut axis that the gut and the liver are closely related in anatomy and function, that they influence each other, and they affect the process of liver disease.

Modern research on traditional Chinese medicine in the treatment of NAFLD based on the “liver–gut” axis

A large number of studies (12, 40, 41) have confirmed that TCM has a positive effect on the regulation of the intestinal flora, and the destruction of the intestinal microecosystem will lead to digestive disorders, poor digestion, and damage to the microecology, further leading to digestive disorders, indigestion, anorexia, and other symptoms, consistent with the liver and kidney syndrome. The use of TCMs for strengthening the spleen and distilling dampness, as such as Chinese yam, *Porzia, Codonopsis,* and *Coix* seed, improves the spleen and stomach deficiency syndrome. Certain components of TCM can play a role in the prevention and treatment of NAFLD by improving the intestinal barrier function. Wang et al. (42) found that the *Ophiopogon japonicus* polysaccharide MDG-1 improved NAFLD in mice fed a high-fat diet by regulating the gut microbiota and hepatic lipid metabolism. Zhang et al. (43) showed that berberine can reduce liver inflammation and lipid deposition in NAFLD mice, which may be related to its role in
regulating the intestinal flora. Qi et al. (44) also discovered that berberine hydrochloride can repair the intestinal mechanical barrier function of NAFLD rats and alleviate the steatosis of the liver caused by NAFLD. With the deepening of research on TCM compounds, many of these compounds based on the “liver and spleen theory” have been proven to be able to treat NAFLD by regulating the intestinal barrier. Fang (45) found that Dahuang Zexie Decoction reduced the level of pathogenic bacteria in the intestine of NAFLD rats, thereby reducing the production of LPS, regulating the function of the intestinal mechanical barrier, and improving the inflammation and lipid deposition of the liver. Cui et al. (46) believed that Xiaozhi Yigan Decoction may reduce the liver damage caused by the LPS/TLR4 pathway by improving the intestinal microbial barrier in NAFLD rats. Liver fibrosis is a serious stage in the progression of NAFLD. Chen et al. (47) found that Xiaoyao powder can improve liver fibrosis and restore part of the intestinal flora structure. Removing the spleen-invigorating drugs in the prescription weakens the effect of Xiaoyao powder on the spleen. For liver protection, Shenling Jianpiwei granules have the effect of strengthening the spleen and soothing the liver; moreover, it can reduce the expression of UCP-2 and Cytb in the liver of NAFLD mice, improve the inflammatory response and function of the liver, and protect the liver (48, 49).

In clinical practice, TCM and compound prescriptions are usually boiled in water, and the liquid formulation enters the human gastrointestinal tract after oral administration. Most of the effective ingredients are absorbed in the intestinal tract and react with intestinal microorganisms. The mechanisms of TCM compounds in NAFLD are summarized in Table 1. Yang et al. (50) believed that the intestinal flora including Bifidobacterium, Eubacterium, Enterococcus, and Escherichia are involved in the metabolism of saponins, a class of important active ingredients contained in TCMs such as ginseng and Panax notoginseng, and

| TABLE 1 | Mechanisms of Chinese medicine compounds in non-alcoholic fatty liver disease (NAFLD). |
|-----------------------------------------|-------------------------------------------------------------------------------------|
| **Chinese medicine compound** | **Drug composition** | **Related findings** |
| Liver fat-soluble particles | Astragalus, pueraaria, cassia, rhubarb, orange shade, Salvia miltiorrhiza, seaweed, Zn diarrhea | Enhanced hepatic PPAR-α mRNA expression and decreased hepatic TNF-α expression |
| Eliminate turbidity and protect the gut | Bupleurum, red peony, white peony root, Fructus auranti, zizong, licorice, Salvia miltiorrhiza, hawthorn, Zn diarrhea, peach kernel, safflower, gold, tylo, Angelica, green calyx, plum | Reduced the levels of TNF-α, TNF-β, and CYP2E1 in liver tissues |
| Add flavor to Zn diarrhea soup | Add flavor to Zn diarrhea soup | Inhibited the expression of the TLR4/NF-kB and IL-6, and phospho-c-Jun mRNA and protein expressions |
| Mercy mushroom fat oil | Mountain Cz mushroom, Pinellia, Porz coco, Bupleurum, Salvia miltiorrhiza, Coix seed, Scutellaria baicalensis, Zn diarrhea, Chinese wellberry, hawthorn | Regulated the JNK signaling pathway and downregulated caspase-8, Fasl, and phospho-c-Jun mRNA and protein expressions |
| Small trapped chest soup cutting | Yellow tis, Pinellia, Trichosanthes, wood, turmeric | Downregulated GRP78 and caspase-12 protein expression |
| Tonifying kidney and reducing turbidity | Barbary wellberry, virgin, Polygonum multiflorum, Porz coco, Zn diarrhea, Coix seed, reed root, yam, yellow essence, Yin Chen, defeated sauce grass, licorice | Inhibited the JNK signaling pathway and decreased the JNK1, p-JNK, and p-IRS-1 protein expression |
| Taste water and water two elixir | Golden cherry, Gordon euryale, chinensis, astragalus | Increased the IRS-1 mRNA expression |
| Ginseng Ling spleen and stomach particles | North sand ginseng, Porz coco, Atractylodes, Chinese yam, lentils, lotus seed, amomum of sand, tangerine peel, Coix seed, licorice | Regulated serum and hepatic TNF-α levels and decreased UCP2 and Cyth expression |
| Attached son rational soup | Ginseng, Atractylodes, licorice, dried ginger, aconite | The expression of TNF-α and IL-6 in SREBP-1c and FASN was down regulated |
| Liver corning | White snake grass, potted grass, knotweed, chinensis chinensis, Bupleurum, ginseng, tylo, Salvia miltiorrhiza, yu gold, notoginseng, green wood fragrance, licorice | Reduced the MDA and increased SOD activity |
| Add linglingshu soup | Porz coco, cassia branch, Atractylodes, Dangshen, pinellia, hawthorn, herb grass, safflower, ChinaXiong, Polygonum multiflorum, licorice | Upregulated the expression of AdipoR2 and PPAR-α |
| Protection of liver fat tablets | Ze diarrhea, hawthorn, lotus leaf, puluhuang, notoginseng, tangerine peel | Reduced the Firmicutes/Bacteroidetes ratio and promoted the expression of claudin-1 and ZO-1 proteins |
| Lipid-lowering liver soup | Jersey diarrhea, cassia seed, Salvia miltiorrhiza, yu gold, seaweed, lotus leaves | Decreased APN, TNF-α and regulated occludin and ZO-1 protein levels |

FASN, fatty acid synthase; MDA, malondialdehyde; SOD, superoxide dismutase; APN, adiponectin.
these substances, after the glycosylation of saponins, showed high bioavailability and biological activity. Luo et al. (51) found that rhubarb granules increased the abundance of *Bifidobacterium*, decreased *Enterobacterium* and *Enterococcus*, regulated the intestinal microecological balance, increased the expression of tight junction proteins and blocking proteins in the intestinal mucosa, and reduced enterogenous toxins such as indophenol sulfate. Xu et al. (52) collected cases of NAFLD with damp-heat accumulation. After treatment with modified Yinchen Wuling powder, the authors detected changes in the intestinal flora. The abundance of enterobacteria and *Staphylococcus* decreased, while *Bacteroides*, *Bifidobacterium*, and *Lactobacillus* increased. Yuan et al. (53) revealed that intervention with Guizhi Decoction improved high-fat diet guidance. The intestinal flora of apolipoprotein E (ApoE) knockout mice was unbalanced. After 4 weeks of treatment, the structure of the intestinal flora changed; *Bacteroides* and *Micrococcus verrucosus* increased, while the proportion of *Firmicum* decreased. Kang et al. (54) found that, in rats fed ginseng polysaccharide for a long time, butyric acid-producing bacteria such as chlamydia significantly increased, and the content of SCFAs generated in the colon of rats also significantly increased.

SCFAs are a class of important metabolites produced by specific colonic anaerobes in the intestine after fermenting dietary fiber and resistant starch, mainly including acetic acid, propionic acid, and butyric acid. As important energy sources and signal molecules, SCFAs primarily transmit signals by inhibiting histone deacetylase and G-protein-coupled receptors (55). After the TCM enters the intestine, intestinal microorganisms will decompose and are utilized to generate a large number of SCFAs (Figure 3). On the one hand, SCFAs can be absorbed into the blood through monocarboxylate transporters (MCTs) on intestinal epithelial cells to reach the fat, liver, and other tissues and combine with receptors on target tissues to promote fat decomposition. On the other hand, SCFAs can also stimulate intestinal endocrine cells to secrete intestinal hormone glucagon peptide 1 and casein to reach the brain, pancreas, and other tissues, inhibiting appetite and energy intake (56). SCFAs can also play an anti-inflammatory role by regulating the chemotaxis of immune cells, the release of reactive oxygen species, and the number and function of intestinal regulatory T cells (Tregs) (57). Moreover, as the main energy source of intestinal epithelial cells, SCFAs can promote the proliferation and differentiation of epithelial cells, reduce cell apoptosis, promote mucin secretion, increase intestinal cross-epithelial resistance and tight connection, and reduce the intestinal mucosal permeability, thereby enhancing the intestinal epithelial barrier function, inhibiting intestinal pathogenic bacteria and intestinal endotoxin LPS from entering the body, and reducing the inflammatory response of body tissues (58). Guo et al. (59) found that the plasma LPS level was significantly negatively correlated with the content of intestinal SCFAs and that Dengzhan Shengmai could improve the intestinal barrier function by increasing SCFAs, which inhibit the entry of intestinal endotoxin LPS into the body, thereby inhibiting the activation of the liver TLR4/NF-κB inflammatory signaling pathway caused by the increase of LPS in mice fed a high-fat diet. Wang et al. (60) confirmed that *Polygonum multiflorum* could regulate the content of SCFAs in the intestine, promote the suitability of SCFAs entering the liver through portal circulation, reduce the accumulation of lipids in...
liver cells, organize intestinal endotoxin translocation, and effectively protect against NAFLD.

Future perspectives

The homeostasis of the intestinal flora plays a crucial role in the maintenance of human health (61), and disturbance in the intestinal flora is closely associated with many diseases (62). At present, more and more studies have been performed on the effects of TCM on the liver–gut axis, but current research is still limited. The relationship between TCM syndromes of fatty liver and the liver–gut axis, elucidating the effect and mechanism of TCM on the intestinal flora and intestinal homeostasis, can provide a new research direction for elucidating the mechanism of action of traditional Chinese medicine. In addition, because the latest biotechnology can be used to detect the intestinal flora, this can improve the level of research on TCM, promote its modernization (63), and provide new ideas for the prevention and treatment of NAFLD.

Author contributions

KG drafted the manuscript. SX researched a lot of information. ZZ critically revised the initial manuscript. All authors contributed to manuscript revision and read and approved the submitted version.

Funding

This study was supported by grants from the Natural Science Foundation of Changsha (kq2202061) and funding from Changsha Science and Technology Bureau.

Conflict of interest

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.
