ZERO LOCI OF ADMISSIBLE NORMAL FUNCTIONS WITH TORSION SINGULARITIES

PATRICK BROSNAN AND GREGORY PEARLSTEIN

Abstract. We show that the zero locus of a normal function on a smooth complex algebraic variety $S$ is algebraic provided that the normal function extends to an admissible normal function on a smooth compactification of $S$ with torsion singularity. This result generalizes our previous result for admissible normal functions on curves [arxiv:0604345]. It has also been obtained by M. Saito using a different method in a recent preprint [arXiv:0803.2771v2].

1. Introduction

Let $H$ be a pure Hodge structure of weight $-1$ with integral structure $H_Z$. Then, the intermediate Jacobian of $H$ is the complex torus $J(H) = H_C/(F^0 + H_Z)$ where $F^*$ is the Hodge filtration of $H$. If $\mathcal{H}$ is a variation of pure Hodge structure over a complex manifold $S$ with integral structure $H_Z$, the above construction produces a holomorphic bundle of complex tori $J(\mathcal{H}) \to S$ with fiber $J(\mathcal{H})_s = J(\mathcal{H}_s)$ over $s$. A normal function $\nu$ is a holomorphic section of $J(\mathcal{H})$ which satisfies a version of Griffiths horizontality. Therefore, as a holomorphic section of $J(\mathcal{H})$, the locus of points $Z$ where $\nu$ vanishes is a complex analytic subvariety of $S$. Furthermore, we have the following conjecture of Griffiths and Green:

Conjecture 1.1. Let $\nu$ be an admissible normal function on a smooth complex algebraic variety $S$. Then, the zero locus $Z$ of $\nu$ is an algebraic subvariety of $S$.

In analogy with the work of Cattani, Deligne and Kaplan on the algebraicity of the locus of a Hodge class, an unconditional proof of this conjecture provides evidence in support of the standard conjectures on the existence of filtrations on Chow groups. In the case where $S$ is a curve, we gave an unconditional proof of (1.1) in [3]. Other special cases in which (1.1) is known are normal functions arising from cycles which are algebraically equivalent to zero and the case where the fibers of $J(\mathcal{H})$ are Abelian varieties. In this paper, we prove the following extension of (3):

Theorem 1.2. Let $\nu$ be an admissible normal function on a smooth complex algebraic variety $S$. Assume that $S$ has a smooth compactification $\bar{S}$ such that $D = \bar{S} - S$ is a smooth divisor. Then, the zero locus $Z$ of $\nu$ is an algebraic subvariety of $S$.

The first step in the proof of Theorem (1.2) is to replace $\nu$ be an admissible variation of mixed Hodge structure $\mathcal{V}$ with integral structure $\mathcal{H}_Z$ and weight graded quotients $Gr^W_0$ and $Gr^W_{-1} = \mathcal{H}$. This is possible by [20]. By a standard construction of Deligne, the mixed Hodge structure on the fiber $\mathcal{V}_s$ defines a...
grading $Y(s)$ of the weight filtration of $\mathcal{Y}$ which preserves the Hodge filtration. The zero locus $\mathcal{Z}$ is then exactly the set of points where $Y(s)$ is defined over $\mathbb{Z}$.

In analogy with [3], the two key technical ingredients in the proof of Theorem (1.2) is the local normal form of a variation of mixed Hodge structure along a normal crossing divisor [19] and the following lemma, which follows from the full strength of the 1-variable $\text{SL}_2$-orbit theorem [18].

**Lemma 1.3.** Let $\mathcal{N}$ be a polydisk and $D \subset \mathcal{N}$ be a smooth analytic hypersurface. Let $\mathcal{Y}$ be a variation of mixed Hodge structure over the complement of $D$ with weight graded quotients $\text{Gr}_0^W$ and $\text{Gr}_1^W$. Assume that the monodromy $T = e^N$ of $\mathcal{Y}$ about $D$ is unipotent. Then, for each point $p \in D$, the limit

$$\hat{Y}(p) = \lim_{s \to p} Y(s)$$

exists, is contained in the kernel of $\text{ad}N$ and has an explicit description in terms of $N$ and the $\mathfrak{sl}_2$-splitting of the limit mixed Hodge structure of $\mathcal{Y}$ at $p$.

**Remark 1.4.** The limit mixed Hodge structure of $\mathcal{Y}$ at $p$ depends upon the choice of local coordinates of $S$ at $p$. However, because the limit $\hat{Y}(p)$ belongs to the kernel of $\text{ad}N$, it is well defined independent of the choice of local coordinates.

Alternatively, instead of taking the limit of $Y(s)$ as $s$ accumulates to $p \in D$ along a sequence of points in $S$, one can twist $Y(s)$ by $e^{\frac{1}{2}\text{log}(s)N}$ in analogy with the construction of the limit mixed Hodge structure. This gives a corresponding grading $Y(p)$ which belongs to the kernel of $\text{ad}N$ and has an explicit description in terms of the limit mixed Hodge structure of $\mathcal{Y}$ at $p$. This is stated explicitly in Theorem (4.15) of [18].

In terms of the grading $Y(s)$, the normal function $v$ is constructed as follows: Let $Y_Z$ be an integral grading of some reference fiber of $\mathcal{Y}$. Then, $Y_Z$ extends to a multivalued, integral grading of the weight filtration of $\mathcal{Y}$ over $S$. Therefore, the difference $Y(s) - Y_Z$ is a well defined map from $\mathbb{Z}(0)$ into $J(\mathcal{H})$ for each point $s \in S$. The normal function $v$ is the image of $1 \in \mathbb{Z}(0)$ under this map. This suggests setting

$$J(\mathcal{H})_p = \text{Ext}_1^{\text{MHS}}(\mathbb{Z}(0), K)$$

where $K$ is the induced mixed Hodge structure on $\ker(N : H_C \to H_C)$ and defining

$$v'(p) = (Y(p) - Y_Z)(1) \in J(\mathcal{H})_p$$

where $T = e^N$ is the local monodromy of $\mathcal{Y}$ at $p$ (assumed unipotent), $F_{\infty}$ is the limit Hodge filtration of $\mathcal{H}$ at $p$, and $Y_Z$ is an integral grading of the weight filtration which is invariant under $T$.

In general, the existence of such a grading $Y_Z$ is obstructed by the class $\sigma_{E,p}(v)$ of $v$ in the finite group

$$G = \frac{H_Z \cap (T - 1)(H_Z)}{(T - 1)(H_Z)}$$

(1.5)

In analogy with [12], this allows one to construct a “Neron model” which graphs admissible normal functions on a neighborhood of $p$: In general, the fibers of $\hat{J}(\mathcal{H})$ can not patch together to form a complex analytic space, since the dimension of $J(\mathcal{H})_p$ can be less than the dimension of $J(\mathcal{H})_s$ for $s \in S$. Nonetheless, $\hat{J}(\mathcal{H})$ does carry a kind of generalized complex analytic structure (“slit analytic
space") which traces back to the fundamental work of Kato and Usui compactification of period domains [17]. For recent work in this direction see [21] which uses the Neron model of [12] to give a proof of Theorem [1.2] independent of ours.

Our original interest in the construction of the limits of normal functions is rooted in the work of Griffiths and Green [11] on singularities of normal functions and the Hodge conjecture. Very briefly, the idea of [11] is to start with a smooth projective variety $X$ of complex dimension $2n$ and a very ample line bundle $L$ on $X$. Let $|L| = \mathbb{P}H^0(X, L)$ and $S$ be the complement of the dual variety $\bar{X} \subset |L|$ of $X$. Then (cf. [11]), a primitive Deligne cohomology class $\zeta \in H^{2n}_D(\mathbb{C}, \mathbb{Z}(n))$ determines an admissible normal function $\nu$ on $S$ with cohomology class $c_1(\nu) \in H^1(S, \mathbb{H}_Z)$. We then say that $\nu$ is singular on $|L|$ if there is a point $p \in \bar{X}$ such that

\begin{equation}
\sigma_{z,p}(\nu) = \colim_{p \in U} c_1(\nu)|_{U \cap S} \in \colim_{p \in U} H^1(S \cap U, \mathbb{H}_Z)
\end{equation}

is non-torsion, where the colimit is taken over all complex analytic neighborhoods $U$ of $p$ in $|L|$. The Hodge conjecture is then equivalent to the following statement [11, 1].

**Conjecture 1.7.** For each primitive, non-torsion Hodge class $\zeta \in H^{n,n}(X, \mathbb{Z})$ there exists a positive integer $k$ such that $\nu$ is singular on $|L|^k$.

**Remark 1.8.** The definition of $\sigma_{z,p}(\nu)$ is valid for any admissible normal function defined on the complement of a divisor $D \subset \bar{S}$. The finite group (1.5) is exactly the torsion part of the cohomology group appearing in (1.6). In case where $D$ is a smooth divisor, admissibility forces $\sigma_{z,p}(\nu)$ to be torsion.

Simple examples show that, in general, unless $\sigma_{z,p}(\nu) = 0$ the limit of $Y(s)$ along a holomorphic arc $\gamma$ through $p$ depends upon the multiplicities (assumed finite) of the intersection of $\gamma$ with the irreducible components of the (normal crossing) boundary divisor at $p$. However, we will show that if $\sigma_{z,p} = 0$, the limit $Y(s)$ is independent of $\gamma$. Furthermore, modulo one step which we shall defer to [2], we obtain the following result:

**Theorem 1.9.** Let $\nu$ be an admissible normal function on a smooth complex algebraic variety $S \subset \bar{S}$. Assume that $D = \bar{S} - S$ is a normal crossing divisor and that $\sigma_{z,p}(\nu)$ is torsion for every point $p \in D$. Then, the zero locus of $\nu$ is an algebraic subvariety of $S$.

**Remark 1.10.** In fact, the assumption that $D$ is a normal crossing divisor is not necessary. To see this, suppose that we know the result in the case that $D$ is a normal crossing divisor. Let $\nu$ be an admissible normal function on $\bar{S}$ which is smooth over $S$. By Hironaka, we can find a resolution $p : \bar{T} \to \bar{S}$ such that $p^{-1}S \to S$ is an isomorphism and $p^{-1}(\bar{S} \setminus S)$ is a normal crossing divisor. It is easy to see that, if the singularity of $\nu$ is zero at every point in $\bar{S}$, then the singularity of the pullback of $\nu$ to $\bar{T}$ is zero on $\bar{T}$ as well. Thus, by the theorem, the zero locus of $\nu$ on $S = \bar{T} \setminus p^{-1}S$ is algebraic.

**Remark 1.11.** As mentioned above, Morihiko Saito has obtained an independent proof of Theorem [1.2]. He also obtains Theorem [1.9] See [21].
2. PRELIMINARY RESULTS

2.1. Gradings and Splittings. Let $V$ be a finite dimensional vector space over a field $k$ of characteristic zero, and

$$0 = L_0 \subseteq \cdots \subseteq L_i \subseteq \cdots \subseteq L_b = V$$

be an increasing filtration of $V$ indexed by $\mathbb{Z}$. Then, a grading of $L$ is a semisimple endomorphism $Y$ of $V$ such that

$$L_i = E_i(Y) \oplus L_{i-1}$$

for each index $i$, where $E_i(Y)$ is the $i$-eigenspace of $Y$. Elements of $\text{GL}(V)$ which preserve $L$ act on gradings of $L$ by the adjoint action:

$$g.Y = gYg^{-1}$$

Let $(F, W)$ be a mixed Hodge structure with Hodge filtration $F$ and weight filtration $W$. Then [8] there exists a unique, functorial bigrading $V_C = \bigoplus_{p,q} I^{p,q}$ of the underlying vector space $V_C$ such that

(a) $F_p = \bigoplus_{r \geq p} I^{r,s}$;
(b) $W_k = \bigoplus_{r+s \leq k} I^{r,s}$;
(c) $I^{p,q} = I_{p+q} \mod \bigoplus_{r+q<s<p} I^{r,s}$.

The associated Deligne grading $Y_{(F, W)}$ of $W$ is the semisimple endomorphism of $V_C$ which acts as multiplication by $p+q$ on $I^{p,q}$. In particular, by properties (a)–(c), if $g$ is an element of $\text{GL}(V_{\mathbb{R}})$ which preserves $W$ then

$$I^{p,q}_{(g, F, W)} = g I^{p,q}_{(F, W)}$$

with respect to the linear action of $\text{GL}(V)$ on filtrations and subspaces. Likewise, for $g$ as above $Y_{(g, F, W)} = g Y_{(F, W)}$.

The mixed Hodge structure $(F, W)$ induces a mixed Hodge structure on the Lie algebra $\mathfrak{gl}(V_C)$ with associated bigrading

$$\mathfrak{gl}(V_C) = \bigoplus_{p,q} \mathfrak{gl}(V)^{p,q}$$

Let $\lambda$ be an element of the subalgebra

$$\Lambda^{-1,-1} = \bigoplus_{a,b<0} \mathfrak{gl}(V)^{a,b}$$

Then, by properties (a)–(c),

$$I^{p,q}_{(e^\lambda, F, W)} = e^{\lambda} I^{p,q}_{(F, W)}$$

and hence $Y_{(e^\lambda, F, W)} = e^{\lambda} Y_{(F, W)}$.

**Definition 2.3.** A mixed Hodge structure $(F, W)$ is split over $\mathbb{R}$ if $I^{p,q} = I^{p+q}$.

**Lemma 2.4.** Let $(F, W)$ be a mixed Hodge structure. Then, the following are equivalent:

(a) $(F, W)$ is split over $\mathbb{R}$;
(b) $I^{p,q}_{(F, W)} = F^p \cap \hat{F}^q \cap W_{p+q}$.
(c) There exists a grading $Y$ of $W$ which preserves $F$ and is defined over $\mathbb{R}$, in which case $Y = Y_{(F,W)}$.

If $(F,W)$ is not split over $\mathbb{R}$ we can construct an associated split mixed Hodge structure $(e^{-i\delta}F,W)$ as follows:

**Theorem 2.5** (Prop (2.20) [6]). There exists a unique real element $\delta$ in $\Lambda^{-1,-1}$ such that $\tilde{Y}_{(F,W)} = e^{-2i\delta}Y_{(F,W)}$. Moreover, $\delta$ commutes with all $(r,r)$-morphism of $(F,W)$ and

$$ (e^{-i\delta}F,W) $$

is split over $\mathbb{R}$.

Let $W$ be an increasing filtration of $V$ and $N$ be a nilpotent endomorphism of $V$ which preserves $W$. Assume that the relative weight filtration $M$ of $N$ and $W$ exists, and suppose that there exists a grading $Y_M$ of $M$ which preserves $W$ and satisfies the condition

$$ [Y_M,N] = -2N $$

Let $Y$ be a grading of $W$ which preserves $M$, and

$$ N = N_0 + N_{-1} + \cdots $$

be the decomposition of $N$ with respect to $\text{ad} Y$ (i.e. $[Y,N_{-j}] = -jN_{-j}$).

**Lemma 2.8.** (Deligne [7, 13]) Under the hypothesis of the previous paragraph, there exists a unique, functorial grading $Y = Y(N,Y_M)$ of $W$ which preserves $Y_M$ such that:

(a) $(N_0,H)$ is an $sl_2$-pair where $H = Y_M - Y$;

(b) If $(N_0,H,N_0^+)$ is the associated $sl_2$-triple then $[N-N_0,N_0^+] = 0$.

**Corollary 2.9.** For $k > 0$, $N_{-k}$ is either zero or a highest weight vector of weight $k - 2$ with respect the representation of $sl_2$ constructed in the previous lemma. In particular, $N_{-1} = 0$.

### 2.2. Admissible nilpotent orbits.

Let $\mathcal{V} \to S$ be a variation of mixed Hodge structure over a complex manifold. Then [19, 23], in analogy with a variation of pure Hodge structure, a choice of reference fiber $V$ for $\mathcal{V}$ allows us to represent $\mathcal{V}$ by a period map $\phi : S \to \Gamma \backslash \mathcal{M}$ where $\mathcal{M}$ is a suitable classifying space of graded-polarized mixed Hodge structures and $\Gamma$ is the image of the monodromy representation. As in the pure case, the classifying space $\mathcal{M}$ is a submanifold of a suitable flag variety, and the period map $\phi$ is holomorphic, horizontal and locally liftable. If $F : \tilde{S} \to \mathcal{M}$ is a lifting of $\phi$ to the universal cover of $S$, then

$$ \frac{\partial F_p}{\partial z_j} \subseteq F^{p-1}, \quad \frac{\partial F_p}{\partial \bar{z}_j} \subseteq F^p $$

where $(z_1, \ldots, z_r)$ are local holomorphic coordinates on $\tilde{S}$.

More precisely, let $Q_*$ be the graded-polarizations of $Gr^W$ and $GL(V)^W$ denote the subgroup of $GL(V)$ consisting of elements which preserve $W$. Define

$$ G = \{ g \in GL(V)^W \mid Gr(g) \in \text{Aut}_{\mathbb{R}}(Q_*) \} $$
to be the subgroup of $GL(V)^W$ consisting of elements which act by real isometries of $Q$ on $G_r^W$. Then, in analogy with the pure case, $G$ acts transitively on $\mathcal{M}$ by biholomorphisms. Likewise, we have an embedding of $\mathcal{M}$ into its “compact dual”

$$\mathcal{M} = G/G^F \leftarrow G_C/G^F_C = \mathcal{M}$$

where $G_C = \{ g \in GL(V)^W | Gr(g) \in Aut_C(Q) \}$, and $G^F, G^F_C$ are the corresponding isotopy groups of some point $F \in \mathcal{M}$. The set of points $F \in \mathcal{M}$ for which the corresponding mixed Hodge structure $(F, W)$ is split over $\mathbb{R}$ is a homogeneous space for the Lie group $G_\mathbb{R} = G \cap GL(V_\mathbb{R})$. Define $g_\mathbb{R}$ and $g_C$ to be the respective Lie algebras of $G_\mathbb{R}$ and $G_C$.

Let $\Delta \subset \mathbb{C}$ be the unit disk and $\mathcal{V}$ be a variation of mixed Hodge structure on the complement $\Delta^*$ of the origin with unipotent monodromy $T = e^N$. Then, we have a commutative diagram

$$
\begin{array}{ccc}
U & \xrightarrow{F} & \mathcal{M} \\
\vcenter{\xymatrix{\Delta^* \ar[r]^-{\phi} \ar[d] & \Gamma \backslash \mathcal{M} \ar[d]}} & \\
\end{array}
$$

Therefore, $\psi(z) = e^{-zN}F(z) : \Delta^* \to \mathcal{M}$ descends to a well defined holomorphic map $\psi : \Delta^* \to \mathcal{M}$. If $\mathcal{V}$ is admissible then [22]

(a) $F_\infty = \lim_{t \to -\infty} \psi(s) \in \mathcal{M}$ exists;

(b) The relative weight filtration $M$ of $N$ and $W$ exists.

In this case [22],

(i) $(F_\infty, M)$ is a mixed Hodge structure relative to which $N$ is a $(-1, -1)$-morphism;

(ii) $(e^{\infty N}, F_\infty, W)$ is an admissible nilpotent orbit.

For variations of mixed Hodge structure over a higher dimensional base, Kashiwara defined admissibility via a curve test [14]. In particular, if $\mathcal{V}$ is an admissible variation of mixed Hodge structure defined on the complement of a normal crossing divisor with unipotent monodromy transformations $T_j = e^{N_j}$, then the relative weight filtration $M(N_j, W)$ of $W$ and $N_j$ exists for each $j$.

The remainder of this section is devoted to the discussion of the 1-variable $SL_2$-orbit theorem [18] which allows us to approximate the nilpotent orbit $\theta(z)$ by an associated $SL_2$-orbit $\theta(z)$ arising from a representation $\rho : SL_2(\mathbb{R}) \to G_\mathbb{R}$.

We start by returning to Lemma (2.8):

**Lemma 2.10.** (Deligne [7][13]) Let $(F, N, W)$ define an admissible nilpotent orbit with relative weight filtration $M$. Let $Y_M = Y_{(F, M)}$ and $\bar{Y} = Y_N, Y_M$ be the associated grading of Lemma (2.8). Then, $\bar{Y}$ preserves $F$. If $(F, M)$ is split over $\mathbb{R}$ then $\bar{Y} = Y$.

**Proof:** This follows from the functoriality of Deligne’s grading together with an explicit computation in the case where $(F, M)$ is split over $\mathbb{R}$. □

**Definition 2.11.** A mixed Hodge structure $(F, W)$ is of type (I) if there exists an index $i$ such that $Gr_i^W = 0$ unless $k = i, i+1$.

**Lemma 2.12.** Every mixed Hodge structure of type (I) is split over $\mathbb{R}$.
Proof: This follows directly from the short length of the weight filtration and property (c) of Deligne’s bigrading. □

Combining the above result, we now obtain a formula for $Y(e^{\delta}; F, W)$ along an admissible nilpotent orbit of type (I), i.e. $(e^{\delta}; F, W)$ is mixed Hodge structure of type (I) for $Im(\delta) > 0$, when the associated limit mixed Hodge structure $(F, M)$ is split over $\mathbb{R}$:

Theorem 2.13. Let $(e^{\delta}; F, W)$ be an admissible nilpotent orbit of type (I). Let $Y = Y(N, Y_M)$ be the associated grading of $W$ of Lemma (2.10), and suppose that $(F, M)$ is split over $\mathbb{R}$. Then, for $Im(\delta) > 0$:

\begin{equation}
Y = Y(e^{\delta}; F, W)
\end{equation}

Proof: The fact that $(e^{\delta}; F, W)$ is a mixed Hodge structure for $Im(\delta) > 0$ follows from the fact that $(F, M)$ is split over $\mathbb{R}$ and the results of [6]. By Corollary (2.9) and the short length of $W$, $N_0 = N$. Therefore, $Y$ preserves $e^{\delta}; F$ since $[\gamma, N] = 0$ and $Y$ preserves $F$ by Lemma (2.10). As $Y$ is defined over $\mathbb{R}$, (2.14) now follows from part (c) of Lemma (2.4). □

The next result allows us to compute the asymptotic behavior of $Y(e^{\delta}; F, W)$ along an arbitrary admissible nilpotent orbit of type (I).

Theorem 2.15. (SL$_2$-orbit theorem [18]) Let $(e^{\delta}; F, W)$ be an admissible nilpotent orbit of type (I) with relative weight filtration $M$. Let $(\tilde{F}, M) = (e^{-i\delta}; F, M)$ denote Deligne’s $\delta$-splitting (2.6) of $(F, M)$. Then, there exists an element

\[ \zeta \in \mathfrak{g}_R \cap \ker(ad N) \cap \Lambda_{(F, M)}^{1, -1} \]

and a distinguished real analytic function $\tilde{g} : (a, \infty) \to G_\mathbb{R}$ such that

(a) $e^{\delta y} F = \tilde{g}(y) e^{\delta y} \tilde{F}$ for $y > a$;

(b) $\tilde{g}(y)$ and $\tilde{g}^{-1}(y)$ have convergent series expansions about $\infty$ of the form

\[
\begin{align*}
\tilde{g}(y) &= e^\zeta (1 + \tilde{g}_1 y^{-1} + \tilde{g}_2 y^{-2} + \cdots ) \\
\tilde{g}^{-1}(y) &= e^{-\zeta} (1 + \tilde{f}_1 y^{-1} + \tilde{f}_2 y^{-2} + \cdots )
\end{align*}
\]

with $\tilde{g}_k, \tilde{f}_k \in \ker(ad N)^{k+1}$;

(c) $\delta$, $\zeta$ and the coefficients $\tilde{g}_k$ are related by the formula

\[ e^{i\delta} = e^{\zeta} \left( 1 + \sum_{k=0}^{\infty} \frac{(-i)^k}{k!} (ad N)^k \tilde{g}_k \right) \]

Let $(N_0, H, N_0^\perp)$ be the sl$_2$-triple determined by the sl$_2$-pair of Lemma (2.10) and the nilpotent orbit $e^{\delta} F$. The constant $\zeta$ can be expressed as a universal Lie polynomial in the Hodge components $\delta^{r,s}$ of $\delta$ with respect to $(\tilde{F}, M)$. Likewise the coefficients $\tilde{g}_k$ and $\tilde{f}_k$ can be expressed as universal Lie polynomials in the Hodge components $\delta^{r,s}$ and $ad N_0^\perp$.

Remark 2.16. As noted in the proof of Corollary (2.13), for orbits of type (I), $N = N_0$.

For the purpose of computing the asymptotic behavior of the limit grading in §3, it is useful to renormalize the SL$_2$-orbit theorem as follows: Let

\[ g(y) = \tilde{g}(y) e^{-\zeta}, \quad \tilde{F} = e^{\zeta} \tilde{F} \]
Then, $e^{i\theta N}F = g(y)e^{i\theta N}\hat{F}$ since $[N, \zeta] = 0$. The mixed Hodge structure $(\hat{F}, M)$ is split over $\mathbb{R}$ since $(\hat{F}, M)$ is split over $\mathbb{R}$ and $\zeta \in g_{\mathbb{R}}$. Moreover, 

$$e^{-\hat{\xi}} = e^{\hat{\xi}}e^{-i\delta} \in \exp(\Lambda_{-1,-1})$$

commutes with $N$ and is a universal polynomial in the Hodge components of $\delta$. Likewise, the coefficients $g_k = \text{Ad}(e^{\hat{\xi}})\tilde{g}_k$ of the series expansion

$$g(y) = 1 + \sum_{k>0} g_k y^{-k}$$

are universal polynomials in the Hodge components of $\delta$ and $\text{ad}N_0^+$, and satisfy the identity $g_k \in \ker(\text{ad}N_0^+)^{k+1}$.

**Definition 2.17.** Let $(e^{i\theta N}F, W)$ be a nilpotent orbit of type $(I)$. Then, $\hat{F} = e^{-\hat{\xi}}F$ is the $sl_2$-splitting of $(F, M)$.

**Remark 2.18.** By virtue of the fact that $\zeta$ is given by a universal polynomial in the Hodge components of $\delta$, the $sl_2$-splitting is defined for any mixed Hodge structure. The formula is as follows [16]: Write the Campbell–Baker–Hausdorff formula as $e^\alpha e^\beta = e^{H(\alpha, \beta)}$. Then, $\delta$ and $\xi$ are related by the formula

$$\delta = H(\xi, -\bar{\xi})/2\sqrt{-1}$$

**2.3. Local normal form.** Let $\Delta$ be a polydisk with local coordinates $(s_1, \ldots, s_r)$ and $\mathcal{V}$ be an admissible variation of mixed Hodge structure on the complement of the divisor $s_1 \cdots s_r = 0$ with unipotent monodromy $T_j = e^{N_j}$ about $s_j = 0$. Then, the $I^p,q$'s of the limit mixed Hodge structure $(F_\infty, M)$ define a vector space complement

$$q = \bigoplus_{a < 0} g_{a,b}$$

to the isotopy algebra $g_{\mathbb{C}}^{F_\infty}$, and hence by admissibility, near $p$ we can write the Hodge filtration of $\mathcal{V}$ as

$$F(z) = e^{\Sigma_i z_i N_i} e^{\Gamma(z)} F_\infty$$

where $\Gamma(s)$ is a $q$-valued function which vanishes at $s = 0$ and $s_j = e^{2\pi i s_j}$. By horizontality,

$$\frac{\partial}{\partial z_j} F^p(z) \subseteq F^{p-1}(z)$$

Let $g_a = \bigoplus_b g_{a,b}$ and note that:

(i) $q = \bigoplus_{a < 0} g_a$;

(ii) $[g_a, g_b] \subseteq g_{a+b}$;

(iii) $N_j \in q_{-1}$.

Inserting (2.19) into (2.20) it then follows that

$$\text{Ad}(e^{-\Gamma(s)}) N_j + 2\pi i s_j e^{-\Gamma(s)} \frac{\partial}{\partial z_j} e^{\Gamma(s)} \in q_{-1}$$
Taking the limit as \( s_j \to 0 \) in (2.21) it then follows by (i)–(iii) that
\[
(2.22) \quad \Gamma^{(j)}_s \cdot N_j = 0
\]
where \( \Gamma^{(j)}_s \) denotes the restriction of \( \Gamma(s) \) to the slice \( s_j = 0 \).

**Remark 2.23.** In the pure case, this result is due to Cattani and Kaplan [5].

**Remark 2.24.** The results of this section remain valid in the case where \( \mathcal{V} \) is a variation over \( \Delta^a \times \Delta^b \) upon setting \( N_j = 0 \) for \( j = a + 1, \ldots, b \).

### 2.4. Intersection Cohomology

Let \( \mathcal{A}_Q \) be a local system of \( \mathbb{Q} \)-vector spaces over a product of punctured disks \( \Delta^r \) with unipotent monodromy. Let \( A_Q \) be a reference fiber of \( \mathcal{A}_Q \) and \( N_j \in \text{Hom}(A_Q, A_Q) \) denote the monodromy logarithm of \( \mathcal{A}_Q \) about the \( j \)’th disk. Then, because the \( N_j \)'s commute, the vector spaces
\[
(2.25) \quad B^p(N_1, \ldots, N_r; A_Q) = \bigoplus_{1 \leq j_1 < \cdots < j_p \leq r} N_{j_1} \cdots N_{j_p}(A_Q)
\]
form a complex with respect to the differential \( d \) which acts on the summands of (2.25) by the rule
\[
(2.26) \quad d : N_{j_1} \cdots N_{j_p}(A_Q) \xrightarrow{(-1)^{\#N_q}} N_{j_1} \cdots N_{j_p}(A_Q)
\]
Let \( j : \Delta^r \to \Delta' \) be a holomorphic embedding (the open inclusion) of \( \Delta^r \) in a product of disks \( \Delta' \) and define
\[
\text{IH}^p(\Delta', \mathcal{A}_Q) = \mathbb{H}^p(\Delta', j_*, \mathcal{A}_Q)
\]
Then, by [7, 9] or [15] Corollary 3.4.4: \( H^p(B^r(N_1, \ldots, N_r; A_Q) \cong \text{IH}^p(\Delta', \mathcal{A}_Q) \).

The following result follows from Theorem [1] Lemma 2.1.8. Here we give a proof that is more in the spirit of the calculations done in this paper.

**Theorem 2.27.** Let \( \mathcal{V} \to \Delta^r \) be an admissible variation of graded-polarizable mixed Hodge structure with unipotent monodromy which is an extension of \( \mathbb{Q}(0) \) by a variation of Hodge structure \( \mathcal{H} \) of pure weight \( -1 \). Then, the associated short exact sequence
\[
(2.28) \quad 0 \to \mathcal{H}_Q \xrightarrow{\alpha} \mathcal{V}_Q \xrightarrow{\beta} \mathbb{Q}(0) \to 0
\]
induces a long exact sequence
\[
\cdots \to \text{IH}^{p-1}(\Delta', \mathbb{Q}(0)) \xrightarrow{\delta} \text{IH}^p(\Delta', \mathcal{H}_Q) \xrightarrow{\alpha} \text{IH}^p(\Delta', \mathcal{V}_Q) \xrightarrow{\beta} \text{IH}^p(\Delta', \mathbb{Q}(0)) \to \cdots
\]
in intersection cohomology.

**Proof.** Let \( \mathcal{V}_Q \) underlie an admissible extension of \( \mathbb{Q}(0) \) by a variation of pure Hodge structure \( \mathcal{H} \) of weight \( -1 \) and \( B^r(H_Q), B^r(V_Q), B^r(\mathbb{Q}(0)) \) denote the associated complexes (2.25) defined by the local monodromy. By abuse of notation, let \( \text{IH}^p(H_Q) \), etc. denote the cohomology of the the corresponding complex. In particular, since each \( N_j \) acts trivially on \( \mathbb{Q}(0) \),
\[
\text{IH}^0(\mathbb{Q}(0)) = \mathbb{Q}(0), \quad \text{IH}^p(\mathbb{Q}(0)) = 0, \quad p > 0
\]
Furthermore, since \( N_j \) acts trivially on \( \mathbb{Q}(0) \) and \( Gr^H_0(V_Q) \cong \mathbb{Q}(0) \) it then follows that
\[
N_j(V_Q) \subset W_{-1}(V_Q) \cong H_Q
\]
By the existence of the relative weight filtration \( M_j = M(N_j, W) \) and the short length of \( W \) it then follows\(^{22}\) that
\[
N_j(V_Q) = N_j(H_Q)
\]
and hence \( B^p(V_Q) = B^p(H_Q) \) for \( p > 0 \). Consequently,
\[
IH^p(V_Q) = IH^p(H_Q), \quad p > 1
\]
Combining the above results, we therefore obtain the exactness of
\[
\cdots \to IH^{p-1}(Q(0)) \xrightarrow{\partial} IH^p(\mathcal{H}_Q) \xrightarrow{\alpha} IH^p(\mathcal{V}_Q) \xrightarrow{B^*} IH^p(Q(0)) \to \cdots
\]
for \( p > 1 \).

Thus, in order to complete the proof, it remains to prove the exactness of the sequence
\[
(2.29) \quad 0 \to IH^0(H_Q) \to IH^0(V_Q) \to IH^0(Q(0)) \xrightarrow{\partial} IH^1(H_Q) \to IH^1(V_Q) \to 0
\]
By definition,
\[
IH^0(H_Q) = \bigcap_j \ker(N_j|_{H_Q}), \quad IH^0(V_Q) = \bigcap_j \ker(N_j)
\]
and hence the map \( IH^0(H_Q) \to IH^0(V_Q) \) is injective.

To see that \((2.29)\) is exact at \( IH^0(V_Q) \) observe that since \( H_Q = W_{-1}(V_Q) \) and \( Q(0) = Gr^W_0(V_Q) \), the image of \( IH^0(H_Q) \) in \( IH^0(V_Q) \) is exactly the kernel of the map
\[
G^W_0 : IH^0(V_Q) \to IH^0(Q(0))
\]
For any class \([v] \in IH^0(Q(0))\),
\[
\partial [v] = (N_1(v), \ldots, N_r(v)) \mod dB^0(H_Q)
\]
where \( v \in V_Q \) is any element which projects onto \([v] \in Q(0) = Gr^W_0(V_Q)\). In particular, \( \partial [v] = 0 \) if and only if there exists \( h \in H_Q = W_{-1}(V_Q) \) such that
\[
N_j(v) = N_j(h)
\]
for all \( j \). In this case, \( v = v - h \) defines an element of \( IH^0(V_Q) \) which projects onto of \([v] \in IH^0(Q(0))\) under \((2.30)\). As such, \((2.29)\) is exact at \( IH^0(Q(0))\).

To see that \((2.29)\) is exact at \( IH^1(H_Q) \) suppose that
\[
(N_1(h_1), \ldots, N_r(h_r)), \quad h_j \in H_Q
\]
represents a class \( \eta \in IH^1(H_Q) \) which maps to zero under inclusion in \( IH^1(V_Q) \). Then, there exists a vector \( v \in V_Q \) such that
\[
N_j(h_j) = N_j(v)
\]
for all \( j \). If \( v \in H_Q \) then \( \eta = 0 \). Otherwise, \([v]\) defines a non-zero class in \( IH^0(Q(0))\) such that \( \eta = \partial\tilde{\eta} [v] \). Finally, to verify the surjectivity of the map
\[
IH^1(H_Q) \to IH^1(V_Q)
\]
note that \( B^p(H_Q) = B^p(V_Q) \) for \( p > 0 \) and \( dB^0(H_Q) \subseteq dB^0(V_Q) \). \( \square \)

**Definition 2.32.** Let \([1]\) be the class of 1 in \( IH^0(Q(0)) \) and \( \partial : IH^0(Q(0)) \to IH^1(\mathcal{H}_Q) \) be the connecting homomorphism. Then, \( \text{sing}_p(v) = \Delta 1 \).

**Remark 2.33.** The results of this section remain valid upon replacing \( \mathbb{Q} \) by \( \mathbb{R} \).
2.5. **Invariant Grading.** Let \( v \) be an admissible normal function over a product of punctured disks \( \Delta^\nu \subset \Delta' \) with associated variation of mixed Hodge structure \( \mathcal{Y} \), reference fiber \( V \) and nilpotent orbit \( \theta(z) = e^{\Sigma_j z_j N_j} F_w \). Let \( H_R = Gr^W_0 V_R \) and \( 0 = (0, \ldots, 0) \in \Delta' \). Let \( \hat{\theta}(z) = e^{\Sigma_j z_j N_j} \hat{F} \) be the split (sl2 or Deligne’s \( \delta \)) orbit attached to \( \theta(z) \). Let \( \hat{Y}_M \) denote the corresponding grading of \( (\hat{F}, M) \) where \( M \) is the relative weight filtration of \( W \) and the monodromy cone

\[
\mathcal{C} = \{ \sum_j a_j N_j \mid a_j > 0 \}
\]

Let \( \hat{Y} = Y_{(e^{\nu}, \hat{F}, W)} \), where \( N = \sum_j N_j \). Then, by Lemma (2.10), \( \hat{Y} \) is real, preserves \( \hat{F} \) and commutes with \( N \).

Suppose that \( \text{sing}_0(v) = 0 \) and let \( e_0 \) be the element of \( E_0(\hat{Y}) \) which projects to \( 1 \in \mathbb{R}(0) \). Define \( e_j = N_j(e_0) \).

Then, by (2.31)

\[
(e_1, \ldots, e_r) \in B^1(H_R)
\]

is a representative of \( \text{sing}_p(v) \). Therefore, since \( \text{sing}_p(v) = 0 \) there is an element \( f \in H_R = B^0(H_R) \) such that \( e_j = N_j(f) \). Furthermore, since \( e_j = N_j(e_0) \) and \( e_0 \in \hat{F}^0 \) we have \( e_j \in \hat{F}^{-1} \).

Therefore, by strictness of morphisms of MHS, we can assume \( f \in \hat{F}^0 \). Then,

\[
e_0 - f = e^{N_j(e_0 - f)} \in e^{N_j} \hat{F}^0
\]

Consequently, \( e_0 - f \) belongs to \( I_{(e^{\nu}, \hat{F}, W)} \) since \( e_0 - f \) is real. On the other hand, by theorem of Deligne \( e_0 \) belongs to \( I_{(e^{\nu}, \hat{F}, W)} \). Since \( Gr^W_0 \) has rank 1, it then follows that \( f = 0 \).

**Corollary 2.34.** \( e_0 \in \ker(N_j) \) for all \( j \).

**Corollary 2.35.** If \( \text{sing}_0(v) = 0 \) then

\[
Y_{(e^{\nu}, \hat{F}, W)} = Y_{(e^{\nu}, \hat{F}, W)}
\]

for \( \text{Im}(z_1), \ldots, \text{Im}(z_r) > 0 \).

**Proof:** Since \( e_0 \in \ker(N_j) \) for all \( j \), the grading \( \hat{Y} = Y_{(e^{\nu}, \hat{F}, W)} \) commutes with \( N_1, \ldots, N_r \). Therefore, \( \hat{Y} \) is real and preserves \( e^{\Sigma_j z_j N_j} \hat{F} \) since \( \hat{Y} \) preserves \( \hat{F} \), and hence is the Deligne grading of \( (e^{\Sigma_j z_j N_j} \hat{F}, W) \).

Let \( Y_M = Y_{(F, M)} \). Then, \( Y_M = e^{i\delta} \hat{Y}_M \) and \( Y = Y(N, Y_M) = e^{i\delta} \hat{Y} \). Therefore, since \( [\delta, N_j] = 0 \) for all \( j \), we have:

**Corollary 2.36.** \( [Y, N_j] = 0 \) for all \( j \).

**Definition 2.37.** If \( \text{sing}_0(v) = 0 \) we define \( Y_w \) to be the grading \( Y \) of Corollary (2.36). In particular, since \( Y_w \) commutes with \( N_1, \ldots, N_r \), it is independent of the choice of local coordinates used in its construction.

3. **Limit Grading**

Let \( D \subset S \) be a smooth divisor, \( p \in D \) and \( \Delta^\nu \) be an analytic polydisk in \( S \) containing \( p \). Pick local coordinates \( (s_1, \ldots, s_r) \) on \( \Delta^\nu \) such that \( D \cap \Delta^\nu \) is given by \( s_1 = 0 \). Represent \( v \) by an admissible variation of mixed Hodge structure \( \mathcal{Y} \) over \( \Delta^* \times \Delta^{-1} \) with weight graded quotients \( Gr^W_0 = \mathbb{Z}(0) \) and \( Gr^W_{-1} = \mathcal{H} \). Assume
that the local monodromy of \( \mathcal{V} \) about \( D \) is given by a unipotent transformation \( T = e^{\Gamma} \). Let

\[
F(z; s_2, \ldots, s_r) : U \times \Delta^{r-1} \to M
\]

be a lifting of the local period map of \( \mathcal{V} \) where \( U \) is the upper half-plane.

Let

\[
F(z; s_2, \ldots, s_r) = e^{\delta} F_{\infty}
\]

be the local normal form of the period map of \( \mathcal{V} \) at \( p \). Let \( \Gamma_0(s) = \Gamma(0, s_2, \ldots, s_r) \) and

\[
F_{\infty}(s_2, \ldots, s_r) = e^{\Gamma_0(s, s_r)} F_{\infty}
\]

Let \( W \) be the weight filtration of \( \mathcal{V} \), \( M \) be the relative weight filtration of \( N \) and \( W \). Then,

\[
\theta(z; s_2, \ldots, s_r) = e^N F_{\infty}(s_2, \ldots, s_r)
\]

is an admissible nilpotent orbit in 1-variable which depends complex analytically upon the parameters \((s_2, \ldots, s_r) \in \Delta^{r-1}\). Let

\[
\hat{F}_m(s_2, \ldots, s_r, M) = (e^{-\xi(s_1, \ldots, s_r)} F_{\infty}(s_2, \ldots, s_r), M)
\]

denote the \( sl_2 \)-splitting of \((F_{\infty}(s_2, \ldots, s_r), M) \). Then, \( \xi \) is real analytic in \((s_2, \ldots, s_r) \) since it is given by universal Lie polynomials in the Hodge components of Deligne’s \( \delta \)-splitting of \((F_{\infty}(s_2, \ldots, s_r), M) \).

By the SL\(_2\)-orbit theorem (2.15)

\[
\theta(iy; s_2, \ldots, s_r) = g(y; s_2, \ldots, s_r) e^{iN} \hat{F}_{\infty}(s_2, \ldots, s_r)
\]

where

\[
g(y; s_2, \ldots, s_r) = (1 + \sum_{k=0}^\infty g_k(s_2, \ldots, s_r) y^{-k})
\]

belongs to \( G_R \) and the coefficients \( g_k(s_2, \ldots, s_r) \) are real analytic in \((s_2, \ldots, s_r) \) since they are given by universal Lie polynomials.

We now derive an asymptotic formula for \( Y_{(F(z; s_2, \ldots, s_r), W)} \). Write \( z = x + iy \).

Then,

\[
Y_{(F(z; s_2, \ldots, s_r), W)} = Y_{(e^{iN} \hat{F}_{\infty}(s_2, \ldots, s_r), W)}
\]

\[
e^{iN} Y_{(e^{iN} \hat{F}_{\infty}(s_2, \ldots, s_r), W)}
\]

\[
e^{iN} Y_{(e^{iN} \hat{F}_{\infty}(s_2, \ldots, s_r), W)}
\]

Let \( e^{\Gamma_0} = e^{\Gamma(s)} e^{-\Gamma_0(s)} \) and note that \( s_1 | \Gamma_1 \) in \( \mathcal{O}(\Delta^r) \). Then,

\[
Y_{(F(z; s_2, \ldots, s_r), W)} = e^{iN} Y_{(e^{iN} \hat{F}_{m}(s_2, \ldots, s_r), W)}
\]

\[
e^{iN} Y_{(Ad(e^{iN} \hat{F}_{m}(s_2, \ldots, s_r)), \theta(y; s_2, \ldots, s_r), W)}
\]

\[
e^{iN} Y_{(Ad(e^{iN} \hat{F}_{m}(s_2, \ldots, s_r)), \theta(y; s_2, \ldots, s_r), e^{iN} \hat{F}_{m}(s_2, \ldots, s_r), W)}
\]

Let \( F_0(s_2, \ldots, s_r) = e^{iN} \hat{F}_{m}(s_2, \ldots, s_r) \) and

\[
Y_1 = Y_{(F_0(s_2, \ldots, s_r), W)} \quad \text{and} \quad Y_2 = Y_{(F_\infty(s_2, \ldots, s_r), M)}
\]

Then, by Corollary (2.13):

\[
Y_{(e^{iN} \hat{F}_{m}(s_2, \ldots, s_r), W)} = Y_1
\]

Likewise, since \( N \) and \( H = Y_2 - Y_1 \) is an \( sl_2 \)-pair:

\[
e^{iN} \hat{F}_{m}(s_2, \ldots, s_r) = y^{-H/2} F_0(s_2, \ldots, s_r)
\]
Note that $Y_1$ and $H$ depend real analytically on $(s_2, \ldots, s_r)$.  

**Lemma 3.1.** Let $\gamma(y) = \text{Ad}(e^{-iyN})g(y; s_2, \ldots, s_r)$. Then, $\lim_{y \to \infty} \gamma(y)$ exists, and is real analytic in $(s_2, \ldots, s_r)$.

**Proof:** This follows directly from the fact that $g_k(s_2, \ldots, s_r)$ is real analytic in $(s_2, \ldots, s_r)$ and $g_k \in \text{ker(adN)}^{k+1}$.

Returning to the calculation of $Y(\zeta; s_2, \ldots, s_r)$, and abbreviating $g(y; s_2, \ldots, s_r)$ to $g(y)$, we have

$$
Y(\zeta; s_2, \ldots, s_r) = e^{iN}Y(\text{Ad}(e^{iN})(e^{i(y)})g(y)e^{iN}, F_w(s_2, \ldots, s_r), W)
$$

Let $e^{F_2} = \text{Ad}(\gamma^{-1}(y))e^{F_1}$ and recall that $s_1|\Gamma_1$. Therefore,

$$
Y(\zeta; s_2, \ldots, s_r) = e^{iN}Y(g(y)e^{iN}, F_w(s_2, \ldots, s_r), W)
$$

where $\text{Ad}(y^{H/2})\Gamma_2$ can be uniformly bounded by a constant times $y^e e^{-2\pi y}$ as $y \to \infty$ for some constant $c$.

We now prove Lemma (1.3) of the introduction, which we shall use in the next section to prove the algebraicity of the zero locus $\mathcal{Z}$. Modulo our discussion of dependence on parameters, this essentially the same calculation use to prove the existence of the limit grading in [3].

**Theorem 3.2.** Let $s_1(m), \ldots, s_r(m)$ be a sequence of points in $\Delta^* \times \Delta^* \times \cdot \cdot \cdot$ which converges to $(0, s_2, \ldots, s_r)$ as $m \to \infty$. Let $(z(m), s_2(m), \ldots, s_r(m))$ be a lifting of this sequence to $U \times \Delta^* \times \cdot \cdot \cdot$ with the real part of $z$ restricted to an interval of finite length. Then,

$$
\lim_{m \to \infty} Y(\zeta; s_2, \ldots, s_r, W) = Y(e^{iN}, F_w(s_2, \ldots, s_r), W).
$$

**Proof:** Suppress the dependence of $(z(m); s_2(m), \ldots, s_r(m))$ on $m$. By the previous results:

$$
Y(\zeta; s_2, \ldots, s_r) = e^{iN}g(y)^{H/2}Y(e^{iN}, F_w(s_2, \ldots, s_r), W)
$$

where $\text{Ad}(y^{H/2})(e^{F_2})$ is uniformly bounded by some constant times $y^e e^{-2\pi y}$. Therefore,

$$
Y(e^{iN}, F_w(s_2, \ldots, s_r), W) = Y(e^{iN}, F_w(s_2, \ldots, s_r), W) + \alpha
$$

where $\alpha$ is uniformly bounded by $y^e e^{-2\pi y}$. The result now follows by inserting (3.4) into (3.3) and taking the limit at $m \to \infty$, since $H = H(s_2, \ldots, s_r)$ commutes with $Y_1(s_2, \ldots, s_m)$.  

In order to construct the limit normal function we need the following analog of Theorem (3.2) where we twist the grading $Y_1(\mathcal{F}, \phi)$ by $e^{-\frac{x}{2\pi} \log(x)}$. Again, modulo dependence on parameters, this is really just a glorified version of Theorem (4.15) in [18].
Theorem 3.5. Let \((s_1(m), \ldots, s_r(m))\) be a sequence of points in \(\Delta^r \times \Delta^{-1}\) which converges to \((0, s_2, \ldots, s_r)\) as \(m \to \infty\). Let \((z(m), s_2(m), \ldots, s_r(m))\) be a lifting of this sequence to \(U \times \Delta^{-1}\) with the real part of \(z\) restricted to an interval of finite length. Then,
\[
\lim_{m \to \infty} e^{-zN}Y(F(z(m), s_2(m), \ldots, s_r(m)), W) = Y(N, Y(\tilde{F}_{\infty}(s_2, \ldots, s_r), M))
\]
where \(Y(N, Y(\tilde{F}_{\infty}(s_2, \ldots, s_r), M))\) is the grading of Lemma (2.10).

Proof. We repeat the argument of the proof of Theorem (3.2) to obtain
\[
e^{-zN}Y(F(z(2), \ldots, s_r), W) = e^{-i\eta N}g(y)\bar{y}_{\frac{H}{2}}(Y(\tilde{F}_{\infty}(s_2, \ldots, s_r), W) + \alpha)
\]
(3.6)

By part (c) of the SL_2-orbit theorem (cf. equation (4.19) in [18]), we have
\[
\lim_{y \to \infty} Ad(e^{-i\eta N})g(y) = e^\delta \left(1 + \sum_{k=0}^\infty \frac{(-i)^k}{k!}(ad N)^k \bar{g}_k \right) = e^{i\delta}
\]

Therefore, as in the proof of Theorem (3.2) it follows that
\[
\lim_{m \to \infty} e^{-zN}Y(F(z(2), \ldots, s_r), W) = e^{i\delta}e^{-\zeta}Y(\tilde{F}_{\infty}(s_2, \ldots, s_r), W)
\]
(3.7)

where \(\delta\) and \(\zeta\) are real-analytic in \((s_2, \ldots, s_r)\). By (2.10) and (2.13)
\[
Y(\tilde{F}_{\infty}(s_2, \ldots, s_r), W) = Y(N, Y(\tilde{F}_{\infty}(s_2, \ldots, s_r), M))
\]
(3.8)

by the functoriality of Deligne’s construction. Inserting (3.8) into (3.7) completes the proof.

Remark 3.9. By virtue of the functoriality of the grading \(Y(N, Y_M)\) with respect to the pair \((N, Y_M)\) and the fact that \(Y(N, Y_M) \in \ker(ad)\) due to the short length of \(W\), it follows that \(Y(N, Y_{\tilde{F}_{\infty}(s_2, \ldots, s_r), M})\) is independent of the choice of local coordinates.

In connection with the proof of Theorem (1.9), we now consider the case where \(v\) is an admissible normal function, on \(\Delta^r \subseteq \Delta^t\) with unipotent monodromy, and \(\pi_0(v) = 0\). Let \((s_1(m), \ldots, s_r(m))\) be a sequence of points in \(\Delta^r\) which converge to \(0 = (0, \ldots, 0)\). Let \((z_1(m), \ldots, z_r(m))\) be a lifting of this sequence to the product of upper half-planes, with the real parts of each \(z_j(m)\) restricted to an interval of finite length. Then, we want to compute
\[
\lim_{m \to \infty} Y_{F(z_1(m), \ldots, z_r(m)), W})
\]
where \(F(z_1, \ldots, z_r)\) is a lifting of the local period map to \(U'\). Suppose that (after passage to a subsequence)
\[
\lim_{m \to \infty} \frac{y_{j+1}(m)}{y_j(m)} \in (0, \infty)
\]
for \(j = 1, \ldots, r - 1\). Then, exactly the same arguments as above show that
\[
\lim_{m \to \infty} Y(F(z_1(m), \ldots, z_r(m)), W) = Y(N, Y(\tilde{F}_{\infty}, M))
\]
where $N$ is any element in the monodromy cone $C = \{ \Sigma_j a_j N_j \mid a_j > 0 \}$. The key point is that:

(a) By Corollary (2.35), $\hat{Y} = Y(N, Y_{(\ell^{-\infty}, M)})$ is independent of $N$. 

(b) Under the hypothesis of condition (3.10), the element $N(y_1, \ldots, y_r) = N_1 + \frac{y_2}{y_1} N_2 + \cdots + \frac{y_r}{y_1} N_r$

remains within a compact subset of $C$ as $m \to \infty$. Therefore,

$$e^{\nu_1 N(y_1, \ldots, y_r)_{\infty}} = g(y_1) e^{\nu_1 N(y_1, \ldots, y_r)_{\infty}}$$

where all the coefficients of $g$ depend real-analytically on $N(y_1, \ldots, y_r)$, since Deligne’s construction (2.8) is algebraic in the pair $(N, Y_M)$. 

In general, by reordering the variables if necessary, one can always pass to some subsequence such that

$$\lim_{m \to \infty} \frac{y_{j+1}(m)}{y_j(m)} \in [0, \infty)$$

for $j = 1, \ldots, r - 1$. Suppose for simplicity that $\lim_{m \to \infty} \frac{y_{j+1}(m)}{y_j(m)} = 0$. Then, the main theorem of [16] asserts that

$$\lim_{m \to \infty} Y_{(\nu_1, \ldots, \nu_r)_{\infty}} = 0$$

exists (independent of any assumptions about $\text{sing}(v) = 0$).

**Theorem 3.13.** Assume that $\text{sing}(v) = 0$ and that $(z_1(m), \ldots, z_r(m))$ is a sequence of points in $U^r$ which satisfies condition (3.11). Then,

$$\lim_{m \to \infty} Y_{(F(z_1(m), \ldots, z_r(m)), M)} = Y(\sum_j N_j Y_{(\ell^{-\infty}, M)})$$

**Proof:** This is basically just the main result of [16] together with dependence on parameters (see the proof of the norm estimates in [16] and Corollary (2.35). The details will appear in [2].

## 4. Algebraicity of the Zero Locus

We now prove Theorem (1.2). Let $\mathcal{Z}$ be the zero locus of an admissible normal function $v$ on a smooth complex algebraic variety $\mathcal{S}$ which admits a smooth compactification $\tilde{\mathcal{S}}$ such that $D = \tilde{\mathcal{S}} - \mathcal{S}$ is a smooth divisor. Let $p \in D$ be an accumulation point of $\mathcal{Z}$, and $(s_1, \ldots, s_r)$ be local coordinates on a polydisk $\Delta' \subset \tilde{\mathcal{S}}$ containing $p$, relative to which $D$ is given by the equation $s_1 = 0$. Let $\mathcal{V} = \Delta^* \times \Delta'^{-1}$ be an admissible variation of mixed Hodge structure which represents $v$ on $\mathcal{S} \cap \Delta'$. Without loss of generality, assume that $\mathcal{V}$ has unipotent monodromy.

Let $(s_1(m), \ldots, s_r(m))$ be a sequence of points in $\mathcal{V}$ which converge to $p$, and

$$F(z; s_2, \ldots, s_r) : U \times \Delta'^{-1} \to \mathcal{M}$$

be a lifting of the period map of $\mathcal{V}$, where $U$ is the upper half-plane. Let $(z(m), s_2(m), \ldots, s_r(m))$ be a lifting of $(s_1(m), \ldots, s_r(m))$ to $U \times \Delta'^{-1}$ with the real part of $z$ restricted to an interval of finite length. Then, by Theorem (3.2)

$$\lim_{m \to \infty} Y_{(F(z(m), s_2(m), \ldots, s_r(m)), M)} = Y_1(0, \ldots, 0)$$
In particular, since the set of integral gradings is discrete, equation (4.1) forces
\[ Y_\mathbb{Z} = Y_1(0, \ldots, 0) \]
to be an integral grading of \( W \). By Lemma (2.10) and Corollary (2.13), it then follows that
(a) \( Y_\mathbb{Z} \in \ker(\text{ad}N) \);
(b) \( Y_\mathbb{Z} \) preserves the Hodge filtration \( F_\infty = e^{-\xi}.F_\infty \) of the \( sl_2 \)-splitting the limit mixed Hodge structure \( (F_\infty, M) \);
(c) \( \xi \in \ker(\text{ad}N) \cap \Lambda^{-1,-1}_F(M) \).

Let \( Y_\infty = e^\xi Y_\mathbb{Z} \). Then, \( Y_\infty \) preserves \( F_\infty \) and belongs to \( \ker(\text{ad}N) \). Therefore, due to the short length of the weight filtration, there exists a unique \( g^\infty_C \)-valued function \( f(z; s_2, \ldots, s_r) \) such that
\[ Y_{(F(z; s_2, \ldots, s_r), W)} = e^{\xi} e^{\Gamma(s)}(Y_\infty + f) \]
The local defining equation for \( \mathcal{X} \) near \( p \) is therefore
\[ Y_\mathbb{Z} = e^{\xi} e^{\Gamma(s)}(Y_\infty + f) \]
Transposing the \( e^{N} e^{\Gamma(s)} \) factor over to the other side, we then obtain,
\[ e^{-\Gamma(s)}.Y_\mathbb{Z} = Y_\infty + f \]
The subalgebra \( q \) is closed under the action of \( \text{ad} Y_\infty \). Consequently,
\[ Y_\mathbb{Z} = e^{-\xi}.Y_\infty = Y_\infty + \lambda \]
for some element \( \lambda \in q \). More properly, by equation (2.2), \( \Lambda^{-1,-1}_F(M) = \Lambda^{-1,-1}_c(M) \), wherefrom the result follows since \( \Lambda^{-1,-1}_c(M) \) is closed under \( \text{ad} Y_\infty \).

Accordingly, (4.3) reduces to
\[ e^{-\Gamma(s)}(Y_\infty + \lambda) = Y_\infty + f \]
Again, because \( Y_\infty \) grades \( W \) and \( \text{ad} Y_\infty \) preserves \( q \), we have
\[ e^{-\Gamma(s)}(Y_\infty) = Y_\infty + \alpha(s) \]
for some holomorphic function \( \alpha(s) \) with values in \( q \cap W_{-1}g_C \). Recalling that \( W_{-1}g_C \) acts simply transitively on the gradings of \( W \), it then follows that equation (4.3) simplifies to
\[ e^{-\Gamma(s)}(Y_\infty + \lambda) = Y_\infty \]
since \( g_C = q \oplus g^\infty_C \) and \( f \) takes values in \( g^\infty_C \). Clearly, this equation is complex analytic on \( \Delta^* \). It also forces \( \lambda = 0 \).

Granting Theorem (3.13), the proof of Theorem (1.9) is identical: A sequence of points \( (s_1, \ldots, s_r) \) converging to a point \( p \in D \) where \( \text{sing}_p(v) = 0 \) forces
\[ Y_\mathbb{Z} = Y_{(F_c(M))} \]
to be an integral grading which in the kernel of \( \text{ad} N \) for each \( j \). Repeating the argument given above, it then follows that the local defining equation for the zero locus is \( e^{-\Gamma(s)}(Y_\infty) = Y_\infty \).

**Remark 4.5.** The above arguments also show that if \( v \) is an admissible normal function on \( S = \bar{S} - D \) and \( p \) is a smooth point of \( D \) such that \( \sigma_{2,p}(v) \) is non-zero torsion then \( p \) cannot be an accumulation point of \( \mathcal{X} \).
