Brush border enzymuria originating from proximal renal tubules as sifted test in patients with psoriatic arthritis

Dejan Spasovski*
University Clinic of Rheumatology, Skopje, Republic of Macedonia

Abstract

Aim: To compare diagnostic values and laboratory variables of alanine - aminopeptidase (microsomal AAP), γ-glutamyl transferase (γ-GT), β2-microglobuline (β2-M), C Reactive Protein (CRP) and index for disease activity (PASI) in early diagnosis in previously untreated Psoriatic arthritis (PsA). To determine the effect of untreated Psoriatic arthritis on tubular function, sensitivity of the Brush Border region as well as the diagnostic value of the enzymes originating from proximal renal tubules.

Methods: From the standard methods of the International Federation for Clinical Chemistry (IFCC) we used the kinetic method for determination of alanine - aminopeptidase (microsomal AAP), γ-glutamyl transferase (γ-GT) and MEIA (Microparticles Enzyme Immunoassay(Abbott Axsym system) for determination of β2-microglobuline in urine. We examined samples (serum and urine) from 70 participants (35 PsA untreated, 35 healthy control group). RF and CRP are determined with Latex agglutination test in the same participants.

Results: From 35 examined patients with PsA, 12 pts showed presence of AAP enzymuria (test sensitivity was 34.28%), 8 pts showed presence of γ-GT (test sensitivity was 22.8%), while the presence of β2-microglobuline in urine was low (test sensitivity 0%).

Conclusion: AAP has better sensitivity than γ-GT and β2-microglobuline in the detection of asymptomatic renal endothelial changes in untreated PsA.

Introduction

Brush border region (brush, layer, striated) is composed of microvilli covered with simple cubic and cylindrical epithelium, found in different location of the body. Diameter of the microvilli is 100 nm, while their length very from 100 nm to 200 nm. Because microvilli are so small and dense in the brush border epithelium, they could be seen only with electronic microscope. With light microscope, they could be usually seen collectively as 'fuzzy fringe' (feathered, fibrillary, edgy, borderline), aspart of the surface of the epithelium. The appearance of the 'fuzzy fringe' determines the name Brush border, because this structure resembles the painter brush.

Brush epithelial cells are found in two main locations in the human body.

1. In intestinum: it is the place where absorption takes place. Brush epithelium in the intestinal cover layer is the place of terminal carbohydrate digestion. Microvilli that compose brush epithelium contain enzymes for this terminal part of digestion, located in the apical plasmatic membrane as an integral membrane proteins. These enzymes are located close to the transpoters, which enables absorption of the digested food.

2. In the kidneys: where the brush epithelium is useful to make difference between proximal tubules (that posses brush epithelium) and distal tubules (that do not posses).

Brush border morphology with the brush epithelium, increases the cell surface, especially useful for absorption. The cells that absorb substances have great necessity of contact surface with substances in order to be efficaceous. The luminal surface of the epithelial cells from this segment of the nephron is covered with densely packed microvilli that form border, which can be seen under light microscope. The microvilli in great measure increase the luminal surface of the cells which in great measure facilitate their resorptive function. Membranes inverted inside that form microvilli are the places for numerous sodium pumps.

The cell cytoplasm is densely filled with mitochondria, found mostly in the basal region, inside the curves of the basal plasmatic membrane. The high quantity of the mitochondria gives the cells acidophilic appearance. The mitochondria are necessary for energy supply for the active transportation of the sodium ions outside the proximal tubules. The water passively follows sodium outside the cells according to the concentration gradient. The cubic epithelial cells that cover proximal tubules have extensive lateral interdigitationes between adjacent cells, that seems as there are no cell borders seen under the light microscope. The end resorption of the content of the proximal tubules after drugintake or stop in circulation (in capilars) around tubules leads to disturbance of the cell morphology of the proximal tubule cells, including ejection of the nucleus in the tubular lumen, giving it dirty look in contrast to the clear appearance of the distal tubules, that have completely different characteristics.

Key words: alanine-aminopeptidase (AAP), γ-glutamyl transferase (γ-GT), β2-microglobuline (β2-M), Psoriatic arthritis (PsA)

Received: October 10, 2016; Accepted: November 11, 2016; Published: November 14, 2016
Micrivi have the characteristics of PH parturition. It is the tendency of the acid matters to accumulate in the alkaline fluid compartments, while alkaline matters in acd compartments. So, acid drugs are secreted in great quantities when the urine is alkaline, and vice versa, alkaline drugs are secreted in great quantities when the urine is acid.

The aim of this study is to determine the effect of untreated Psoriatic arthritis on tubular function and sensitivity of the Brush Border of the proximal tubules. AAP, γ-GT, β-2M are used as indicators for proximal tubular damage.

Renal markers for evaluation of the renal function

Several classes of measurable proteins in urine are used for evaluation of the renal dysfunction.

1. Enzymes with high molecular weight, that usually are not filtered in the glomerulus, originating mainly from the proximal tubules (microsomal AAP, NAG).

2. Intermediary proteins that normally are filtered in the glomerulus in small quantities and are reabsorbed in the tubules in great part (albumin, transfierin).

3. Proteins with low molecular weight that normally are filtered in the glomerulus and are reabsorbed in the tubules (β2-microglobuline [1-6].

Alanine-aminopeptidase (AAP), (aryl amide amino acid, aminopeptidase, α- amino-acyl-peptide-hydrolase (microsomal) AAP, ES 3.4.11.2, previously 3.4.1.2) is a hydrolytic derivative of peptides, amides and p-nitroanilide.

AAP is found in numerous tissues, mostly in kidney, intestine, lungs and liver. AAP in different tissues has different electrophoretic conductivity. This enzyme has at least five different isoenzymes that could be separated from each other with electrophoresis, ion-changing chromatography or immunologically. In normal serum is found only one isoenzyme, while in hepatobililar or pancreatic diseases are found additional fractions. The enzyme is also found in urine.

γ-glutamyl transferase (γ-G), (γ-glutamyl-peptide amino acid γ-glutamyl transferase, ES 2.3.2.2. γ-GT catalyzes the transfer of (γ-glutamyl groups with peptides (as glutathione) to other peptides or amino-acids.

γ-GT plays an important role in the glutathione metabolism. High enzyme concentrations are found in kidneys (proximal tubule), pancreas (acinacells), prostate and liver. γ-GT is mostly located on the external part of the plasma membrane [7]. γ-GT isoenzymes in serum are result of the different post-translational modifications as for example complex formations with lipoproteins or modifications of the carbohydrate part of the γ-GT molecule [8]. The possibility of the presence of isoenzymes in different tissues (liver, pancreas, kidney, duodenum) is due to the differences in carbohydrate part of the γ-GT molecule. Although the peptide part of the enzyme molecule is the same no matter the tissue of origin, these isoenzymes differ in kinetic, electrophoretic and immunological features.

The tubular function could be evaluated with measurements of the excreted low molecular proteins in urine. β2-microglobuline (β2-M) is used as an indicator of the tubular disfunctions in glomerulonephritis [9] and is often used as sensitive marker for evaluation of the renal function [10-12]. β2-M is a small polypeptyde with low molecular weight (11.815 daltons). β2-M contains light chains of the main histocompatibility antigen (HLA). It influences production of the RF (IgM class). In normal individuals, β2-microglobuline is found both in serum and urine. 95% of the free β2-M is ultrafiltrated through renal glomerules and almost completely is reabsorbed in 99.9% with proximal tubular endocitosis and finally is catabolized in amino acids in healthy individuals. Due to this mechanism, normally in urine are detected in traces. Imparement in the glomerular filtration leads to increase in serum β2-M, while tubular damage leads to rise in urine β2-M.

Serum concentration of β2-M depends on the glomerular filtration rate (GFR) and shows significant negative correlation with inulin clearence. These findings show that with determination of the serum level of β2-M one could get an index for disfunction of the renal glomerulus.

In some pathological conditions, increased quantities of β2-M are excreted in urine. It happens when β2-M serum concentration exceeds the renal threshold. The serum level of β2-M depends on the ratio of synthesis and release in serum pool and its relation with clearence. Such conditions are notified in patients with inflammatory diseases (Rheumatoid arthritis, SLE, Sv.Sjögren, Crohn disease, cancer, liver damage). β2-M concentration in urine could be increased also when reabsorption is decreased due to renal proximal tubular damage. Proximal tubular dysfunction results with elevated concentrations of urine β2-M, allowing to make distinction between proximal tubular from glomerular renal impairment.

β2-M is used for evaluation of the GFR and renal tubular function, especially for tubulotoxic effect of different substances, such as heavy metals (cadmium and lead) and as a screening test for early detection of Balcan nephritis in regions where it is edemic. In urine β2-M is unstable if ph <6 and it is recommened to alcalize the urine with bicarbonates before it is tested. β2-M is considered the earliest protein of tubular proteinuria.

Material and methods

Diagnosis of the patients included in the study is based upon revised diagnostic criteria for Classification of Psoriatic arthritis from 2005, proposed by the American Association for Rheumatic arthritis (ARA) [13]. Clinical evaluation for disease activity and disease diagnosis is based upon diagnostic criteria of Moll-Wright for Classification of Psoriatic arthritis [14]. Patients are dermatologically tested, including examination of the psoriatic changes of nails, psoriatic areas and disease activity index (PASI) as well as evaluation of the peripheral and axial joints [15]. Oligoarthritis is taken in consideration when <5 joints are involved and polyarthritis when ≥ 5 joints are involved. Symmetric arthritis is considered when bilateral joints are involved >50%.

In the study are included 35 patients (8 women, 27 men) suffering from Psa and 35 patients (23 women, 13 men) as healthy control group. Median age was 50.18 years (SD ± 8.09) (35-65 years) in Psa group, while 48.2 years (SD ± 10.19) (29-65 years) in healthy control group. Median disease duration was 30.17 (SD ± 40.13) in the interval of 1-60 months. None of the patients included in the study has previous or current history of renal disease. None of them previously used NSAIDs. The others negate use of other drugs before entering the study, especially drugs from the base line therapy such as methotrexate, antibiotics or diuretics. Samples are collected in the period of two years.

Inculding criteria

In the study are included patients suffering from Psoriatic arthritis,
Widistributed aged 18-65 years old, newly diagnosed and previously untreated.

Excluding criteria

From the study are excluded all the patients with diseases or conditiones that can directly or indirectly influence the results, such as:

1. Patients < 18 and > 65 years old.
2. Patients with previous history of diseases of the spleen, thyroid gland, liver damages, renal, hematological, cardiovascular, neurological, lung, auto-immune impairments.
3. Patients with diabetes mellitus, acute infections, AIDS, febrile conditions, malignant diseases.
4. Patients previously treated with antibiotics and salicylates <6 months before entering the study.
5. Patients with hypertension, uric arthritis, urinary infections, SLE, Sjögren disease, mixed connective tissue disease, vasculitis.
6. Patients treated with antihypertensive, antidiabetic and cardiovascular drugs.
7. Patients with previous history for blood transfusion and patients with incresed body mass index.
8. Patients with hypersensitivity on drugs or some of their components.
9. Patients with history for drugs from the base line.
10. Patients with acute or chronic renal failure.
11. Patients who in 0-point had glycemia, elevated serum urea and creatinine. Hypertension and impaired hematological and enzyme status.

All the patients took place in the study voluntarily, so the ethic criteria for inclusion in the study are fulfilled.

Laboratory evaluation

For clinical evaluation of the disease one have to examine the following parameters: complete blood count (CBC) and differential, reactants of the acute phase such as C-Reactive Protein (CRP), Rheumatoid factor (RF), Erythroid Sedimenation Rate (ESR), aspartate-aminotransferase (AST), alanine-aminotransferase (ALT), creatinine kinase (CK), lactate – dehydrogenase (LDH), serum urea and serum creatinine. The urine samples were taken not only for routine analyses, but also to determine the levels of AAP, γGT, β-2M.

Determination of creatinine in serum and urine in patients with Rheumatoid arthritis and renal impairment.

GFR (Creatinine Clearance) was estimated by Cockcroft-Gault Equation.

Determination of the activity of alanine amino – peptidase (AAP): kinetic method

Alanine amino-peptidase (aryl amid aminoacid, aminopeptidase, α-aminoacetyl peptide hydrolase (microsomal), ANA, ES 3.4.11.2, former 3.4.1.2.) is hydrolized by peptides, amids and p-nitroanilide. During the process of hydrolization of peptides N-terminal amino acid is seceded (firstly anilide). The activity of AAP is determined by the methods similar to those for determination offucine aminopeptidase. In this method is used L- alanine-4-nitroanilide as a supstrat. The catalytic concentration of AAP is directly proportional to the absorption of p-nitroanilide is measured on 405 nm. Refernt values: urine AAP 0.25-0.75 U/mmol creatinine.

Determination of the activity of γ-glutamyltransferase (γ-GT): IFCC method

γ-glutamyltransferase (γ-glutamyl)–peptide amino acid γ-glutamyltransferase ES 2.3.2.2.γ-GT catalyzes transfer of γ-glutamyl groups with peptides (such as glutathione) on other peptides or aminocids. γ-GT influences the release of glutamyl rest as glutamyn acid. With transpeptidation glytamyl rest could be transfered again on a supstrat (for example from γ-glutamyl-naphtylamide results γ-glutamyl-γ-glutamyl-naphtylamide) or other suitable acceptor (aminoacid, di- or tri-peptide). The most suitable acceptor is glycglycine.

Methods for measurements of the activity of this enzyme in serum use aromatic amids as supstrats (γ-glutamyl-anilide and γ-glutamyl-naphtylamide). The superficial supstrate peptide analogue γ-glutamyl-p-nitroanilide is most frequently used. It is suitable for determination of the enzyme activity kinetically and colorimetrically. γ-glutamyl-p-nitroanilide latter is substituted by L-γ-glytamyl-3-carboxy-4-nitroanilide (glucan) due to its high solubility. Glyculglycine was used as a supstrate acceptor and buffer, due to its high catalytic activity. This method is standardized by the International Federation of Clinical Chemistry-IFCC and is considered as referent method.

Remarks

The IFCC method for measurement of concentration of the catalytic activity of serum and urine γ-GT is based on the principles developed by Orłowski, Meiser and Szasz, and their modification by Persijin and Van der Slik. As a supstrate donor is used L-γ-glytamyl-3-carboxy-4-nitroanilide. In the IFCC method Tris (hydroxymethyl aminooethan is substituted with glycglycine, which acts as buffer and supstrate acceptor. Magnesium which earlier was used for maintenance of L-γ-glytamyl-3-carboxy-4-nitroanilide in the solution in IFCC method is omitted. This method is specific for determination of the activity of γ-GT [17-20].

Refernt values: γ-GT (urine) 0.84-1.80 U/mmol creatinine.

Determination of the concentration β2-microglobuline (β2-M) in urine according to “MEIA” (Microparticles Enzyme Immunoassay) method (Abbott a sym system)

Principles: Determination of a sym β2-microglobuline is based on MEIA technology (Microparticles Enzyme Immunoassay) and enables quantitative determination of β2-microglobuline in serum, plasma and urine in patients with Rheumatoid arthritis and renal impairment.
The reaction is based on the inter-reaction of β2-M with anti-β2-M antibody, forming a mutual complex. This complex reacts with the Matrix cell and is bound to them. A conjugate of alkaline phosphatase is added, it binds to the complex, forming sandwich complex. To this complex is added 4-Methylumbelliferyl Phosphate (4-MUP), reacting with alkaline phosphatase from the complex and a fluorescent product—Methylumbelliferon with light blue colour is made. From the degree of the optic fluorescence depends proportionally the concentration of β2-M. It is determined automatically (Abbott A sym system).

Taking in consideration that β2-M is very sensitive to changes in urine pH i.e., very quickly is degraded in low pH levels. If pH < 6.0 it is monitored, and if it is acid it should be alkalinized.

Referred values: β2-microglobulin (urine) – 0.02-0.19 mg/L

Statistical analysis

For testing the significance of differences between two arithmetical means, i.e., proportions the Student-t-test is used to compare the mean parameters of certain numerical parameters between groups, as well as Wilcoxon-matched test for independent samples. Sensitivity and specificity for positive and negative test of the examined markers is determined with the test for sensitivity and specificity. P-value between 0.05 and 0.1 is considered statistically significant. Analysis of the data is performed with the statistical package Statistica 7.0.

Results

From the 35 examined patients with Psa, 12 pts (34.28%) showed presence of APP enzymuria, 8 pts (22.85%) presence of γ-GT, while β2-microglobulin was 0% and RF sensitivity was 0% (Table 1 and Figure 1).

Diagstic value of alanine aminopeptidase (microsomal AAP) γ-glutamyl transferase (γ-GT), β2 microglobulin (β2M) in Psa

For AAP, γ-GT, β2 microglobulin as well as other laboratory variables in Psa, sensitivity, specificity, predictive values for positive and negative test, as well as accuracy are shown on Table 2.

AAP has better diagnostic performances than γ-GT and β2M in detection of renal impairment in untreated Psa.

Table 1. AAP, γ-GT β2 microglobulin and other laboratory variables in Psa and healthy control group.

| Variable                      | Psa untreated group N=35 | Healthy control group N=35 |
|-------------------------------|---------------------------|-----------------------------|
|                               | Value (M ± SD)            | Value (M ± SD)              |
| AAP + > 0.75 (U/mmol/creatinine) | 12/23                   | 1/34                        |
| γ-GT + > 1.80 (U/ml)          | 8/27                     | 0/35                        |
| β2 M + > 0.19 (mg/L)          | 0/35                     | 0/35                        |
| RF + > 30 (IL/ml)             | 0/35                     | 0/35                        |
| CRP + > 12 (mg/L)             | 13/22                    | 1/34                        |

Discussion

In the standard medical rheumatology the biggest emphasize is put on Rheumatoid arthritis as the most exposed disease, neglecting somehow the other diseases especially seronegative arthropathies, probably due to their lesser extent.
The explanation for the renal tubular enzymes is increased exfoliative turnover of the epithelial cells in PsA, which is adequately present also in proximal tubular epithelial cells.

Of all enzymes, greatest emphasis is put on NAG as dominant lysosomal tubular enzyme. Traditional treatment of PsA and RA, includes non-steroid anti-inflammatory drugs (NSAIDs), disease modifying drugs (DMARDs), steroids and immunosuppressive cytoxic drugs. Methotrexate in low dose regime is the most frequently prescribed drug from DMARDs, while Ketoprofen (Niflam®, Ketonal®) and Paracetamol from NSAIDs.

Enzymes in urine could originate from plasma, glands from the urogenital tract, epithelial cells of the urinary tract, white blood cells, erythrocytes and kidneys. There are 40 different enzymes in the urine belonging to different groups: o xo-d reductases, transferases, hydrolases, lases, while isomerases and lases are not found in urine. Presence of so many enzymes in urine indicates the dominant role of the kidneys in their excretion.

The urine enzyme activity in urine normally is low and increases in renal tubular cell damage. Urinary enzymes especially NAG, AAP and AF are very sensitive indicators of renal parenchymal damage in comparison with functional measurements such as glomerular filtration rate and creatinine clearance. Relatively low sensitivity to GFR could be explained with great functional reserves of the kidneys and their great compensatory ability.

AAP sensitivity is greater in comparison with γ-GT and β2M (34.28% vs. 22.85% vs. 0%), with approximately equal specificity (75.6% vs. 100% vs. 100%).

Statistical relation of disease duration (in months) and AAP and γ-GT and β2M enzymuria p=0.00 points out that untreated PsA damages the renal tissue as one of the visceral manifestations of the disease.

Untreated PsA primarily damages tubular Brush Border region and enzymes originating from it has greater sensitivity [21-29].

Conclusion

AAP has greater sensitivity than γ-GT and β2M in asymptomatic renal lesions in untreated PsA. AAP and γ-GT could be used in everyday clinical practice in diagnosis of early, asymptomatic renal lesions.
