Abstract Magnesium alloys have been widely used in recent years as lightweight structural materials in the manufacturing of automobiles, airplanes, and portable computers. Magnesium alloys have extremely low density (as low as 1738 kg · m$^{-3}$) and high rigidity, which makes them suitable for such applications. In this study, the thermal conductivity of two different magnesium alloys made by twin-roll casting was investigated using the laser-flash technique and differential scanning calorimetry for thermal diffusivity and specific heat capacity measurements, respectively. The thermal diffusivity of the magnesium alloys, AZ31 and AZ61, was measured over the temperature range from $-125^\circ C$ to $400^\circ C$. The alloys AZ31 and AZ61 are composed of magnesium, aluminum, and zinc. The thermal conductivity gradually increased with temperature. The densities of AZ31 and AZ61 were 1754 kg · m$^{-3}$ and 1777 kg · m$^{-3}$, respectively. The thermal conductivity of AZ31 was about 25 % higher than that of AZ61, and this is attributed to the amount of precipitation.

Keywords AZ31 · AZ61 · Low temperature · Magnesium alloy · Thermal conductivity

1 Introduction

Magnesium alloys have a low density, 1738 kg · m$^{-3}$, and a high specific stiffness and are used as lightweight structural materials [1]. Their vibration and shock absorption properties are good, along with their excellent electrical, thermal conductivity, high temperature fatigue, and impact properties. As their densities are lower than that of aluminum (2698 kg · m$^{-3}$), lightweight structures (parts) of popular vehicles, aircraft, transportation equipment, and general machinery are fabricated from magnesium alloys [2,3]. In recent years, devices such as mobile phones and portable laptops have parts made from magnesium alloys to reduce the weight, and as a result, manufacturing research and development in this area are actively ongoing [4]. AZ-series alloys are essentially alloys that include aluminum and zinc, with a magnesium base. AZ31, specifically, is an alloy of 3 mass% Al and 1 mass% Zn, whereas AZ61 is an alloy composed of 6 mass% Al and 1 mass% Zn. AZ91, with added Mn was developed and used for strengthening corrosion resistance [5].

Recently, notebooks require high thermal performance for higher speeds and increased heat dissipation. Such thermal performance is also essential for maintaining an enhanced cooling environment for lightweight parts in automobiles and personal computers. Information about the thermophysical properties of magnesium alloys such as the specific heat capacity and thermal conductivity are relatively scarce. Thus, this article describes a thermal conductivity analysis of magnesium-based alloys of aluminum and zinc, by calculating the thermal conductivity through measurements of the specific heat capacity, thermal diffusivity, and density between $-125 \degree$C and $400 \degree$C.

2 Experimental

Magnesium alloys were made by the twin-roll die casting (TRC) method (POSCO, Korea, AZ31 and AZ61), with magnesium-based compositions of 3 mass% Al and 1 mass% Zn for AZ31 and 6 mass% Al and 1 mass% Zn for AZ61. Three alloy specimens were made for each of the two composition types to be used for measurements of the specific heat capacity and thermal diffusivity. The thermal diffusivity was measured with the laser-flash method (Netzsch LFA 457) between $-125 \degree$C and $400 \degree$C with a Nd:YAG laser and a liquid-nitrogen-cooled MCT infrared detector. The laser pulse width is 0.33 ms to 0.5 ms and the maximum power is 15 J. The environment for the measurements consisted of gaseous helium from $-125 \degree$C to room temperature, in contrast to an environment in the vacuum state from room temperature to 400 $\degree$C. The temperature at the back of the specimen was measured by an mercury-cadmium-telluride (MCT) infrared sensor. The dimensions of the specimens were each 10 mm in diameter and 2 mm in thickness. They were coated with graphite on both sides to allow homogenous absorption of laser energy. Four measurements for the thermal diffusivity were taken at each temperature, and then the mean was used. Standard deviations of the measurements were $<1 \%$. The calculation of the thermal diffusivity used the analysis of Cape and Lehman [6], while the laser pulse-width correction followed the method of Azumi [7]. The specific heat capacity was measured with a differential scanning calorimeter (Perkin Elmer Pyris 1, Netzsch DSC 404C),
and the environment consisting of gaseous argon at a flow rate of 50 mL · min$^{-1}$ was employed in the DSC measurements. A heating rate of 10 K · min$^{-1}$ was applied using SRM-720 (NIST synthetic sapphire) as the standard reference material with a stepwise-scanning method. The density was measured by the Archimedes method. Finally, the thermal conductivity ($\lambda$: W · m$^{-1}$ · K$^{-1}$) was calculated from the measured specific heat capacity ($c_p$: J · g$^{-1}$ · K$^{-1}$), the thermal diffusivity ($\alpha$: m$^2$ · s$^{-1}$) and the density ($\rho$: kg · m$^{-3}$), using the equation,

$$\lambda = \rho c_p \alpha.$$  \hspace{1cm} (1)

We used an optical microscope and scanning electron microscope (SEM) to observe the structure. Each specimen was ground and corroded by Kalling’s agent for usage. SEM–EDS (energy dispersion spectroscopy) was used to evaluate the chemical composition.

### 3 Results and Discussion

Magnesium alloys, used in this study, were manufactured by the TRC method. Table 1 presents the chemical compositions of such magnesium alloys. The chemical compositions of the magnesium alloys included aluminum with a range between 3 mass% and 6 mass%.

Figure 1 is an optical micrograph of AZ31 and AZ61. The grain size of AZ31 is (10 to 30) µm, compared to AZ61 with a grain size of (10 to 20) µm. Similar to El-Morsy [8], our observation on AZ61 confirmed the existence of Al$_{12}$Mg$_{17}$ extracts around the grain boundary of $\alpha$-Mg. Figure 2 shows similar phenomena in SEM micrographs of AZ31 and AZ61. The precipitation of Al$_{12}$Mg$_{17}$ in the solid solution of magnesium is known to affect the thermal conductivity.

The densities of the magnesium alloys, AZ31 and AZ61, were measured to be 1754 kg · m$^{-3}$ and 1777 kg · m$^{-3}$, respectively. Due to the considerably reduced densities compared to aluminum and steel, they have been widely used for reducing the density of the alloys. A recent decrease in the cost of magnesium made it almost as affordable as aluminum [2], and has stimulated further growth in the usage of its alloys.

Figure 3 shows the mean of four thermal-diffusivity measurements for each specimen of AZ31 and AZ61, using the laser flash method. The thermal diffusivity of AZ-series alloys had <1 % standard deviation for each measurement, and the combined uncertainty ($k = 2$) of measurement was about 3 %. The three measurement results agree well within each alloy, as the standard deviation of the thermal diffusivity is <2 %. The thermal diffusivity of AZ31 shows a sharp increase with temperature.

### Table 1: Chemical composition of AZ31 and AZ61 magnesium alloys (mass%)

|       | Al  | Zn  | Mg         |
|-------|-----|-----|------------|
| AZ31  | 3.0 | 1.0 | Balance    |
| AZ61  | 6.2 | 0.9 | Balance    |
at room temperature and below, but a steady increase with temperature at 100 °C or above. The thermal diffusivity of AZ61 displays the same trend, except it is ~25 % lower than that of AZ31 at room temperature. According to Yamasaki and Kawamura [9], AZ61 tends to have a lower thermal conductivity due to the solid solution, given a higher level of aluminum than for AZ31. The measurements of Rudajevova and Lukac [10] for the thermal conductivity of aluminum/magnesium (AM) alloys also show that the thermal conductivity decreases as the amount of aluminum increases. This result is considered to be the effect of Al12Mg17 precipitation.

Figure 4 shows the results of specific heat capacity measurements at 50K increments. The specific heat capacities of AZ31 and AZ61 are not significantly different due to the relatively small difference in aluminum quantities. According to Emsley
[1], the specific heat capacities of magnesium and aluminum at room temperature, 1.0241 J·g⁻¹·K⁻¹ and 0.9025 J·g⁻¹·K⁻¹, respectively, show very little difference. Therefore, changes in the specific heat capacities of magnesium alloys for differing proportions of aluminum are insignificant. The fitted values of the specific heat capacity are displayed in Table 2 and used in the calculations of the thermal conductivity.

In Fig. 5, AZ61 shows a thermal-conductivity range of (45.3 to 83.5) W·m⁻¹·K⁻¹, which is more than (25 to 50) % higher than that of AZ31. The major components of the AZ magnesium alloys are magnesium, aluminum, and zinc, each with a thermal conductivity at room temperature of 156 W·m⁻¹·K⁻¹, 237 W·m⁻¹·K⁻¹,
Table 2  Thermophysical properties of AZ31 and AZ61

| Temperature (°C) | AZ31                |                 | AZ61                |                 |
|------------------|---------------------|----------------|---------------------|----------------|
|                  | Thermal diffusivity  | Specific heat capacity | Thermal conductivity | Specific heat capacity | Thermal conductivity |
|                  | \(10^{-5} \text{m}^2 \cdot \text{s}^{-1}\) | \(\text{J} \cdot \text{g}^{-1} \cdot \text{K}^{-1}\) | \(\text{W} \cdot \text{m}^{-1} \cdot \text{K}^{-1}\) | \(\text{J} \cdot \text{g}^{-1} \cdot \text{K}^{-1}\) | \(\text{W} \cdot \text{m}^{-1} \cdot \text{K}^{-1}\) |
| -125             | 3.9031              | 0.8299         | 67.9                | 2.5697          | 0.8314            |
| -100             | 4.0928              | 0.8778         | 71.2                | 2.7381          | 0.8881            |
| -80              | 4.2361              | 0.9096         | 73.7                | 2.8744          | 0.9231            |
| -30              | 4.5624              | 0.9678         | 79.3                | 3.2118          | 0.9792            |
| 25               | 4.8697              | 1.0059         | 84.7                | 3.5597          | 1.0066            |
| 100              | 5.2049              | 1.0319         | 90.5                | 3.9650          | 1.0188            |
| 200              | 5.5091              | 1.0493         | 95.8                | 4.3486          | 1.0372            |
| 300              | 5.6603              | 1.0689         | 98.4                | 4.5694          | 1.0762            |
| 400              | 5.6699              | 1.0919         | 98.6                | 4.7196          | 1.0986            |
and 116 W m\(^{-1}\) K\(^{-1}\), respectively [1]. The thermal conductivity of AZ31 at room temperature is observed to be 84.7 W m\(^{-1}\) K\(^{-1}\), nearly 25 % higher than the value of 63.2 W m\(^{-1}\) K\(^{-1}\) for AZ61, as Al\(_{12}\)Mg\(_{17}\) precipitations from the aluminum solid solution have a significant effect on the thermal conductivity. AZ31 has a thermal conductivity of 84.7 W m\(^{-1}\) K\(^{-1}\) at room temperature, which is similar when compared to 88.7 W m\(^{-1}\) K\(^{-1}\) (Mg: 97.9 mass%, Al: 2.1 mass%) for a comparable alloy described in the TPRC data book [11]. Also at 100°C, the thermal conductivity of AZ61 is 70.0 W m\(^{-1}\) K\(^{-1}\), which is close to 75.3 W m\(^{-1}\) K\(^{-1}\) for a similar compound (Mg: 94 mass%, Al: 6 mass%) at TPRC.

4 Conclusions

This study provides measurements of the specific heat capacity, thermal diffusivity, and density for two types of magnesium alloys; these results are used to calculate the thermal conductivity. In conclusion, the thermal conductivity showed a tendency to increase with temperature. The thermal conductivity at −125 °C was 20 % less for AZ31 and 28 % less for AZ61 compared to that at room temperature. Also, the thermal conductivity of magnesium alloys decreases with an increase in the percentage of aluminum, due to the interference of a precipitation in a solid solution. The thermophysical property data from this study can be useful in the thermal design for automobiles and notebook applications.
