The present investigation entitled, Phenotypic and Genotypic path coefficient analysis Studies in Chickpea (Cicer arietinum L.) was conducted at Agricultural Research Station, Badnapur, Dist- Jalna (VNMKV, Parbhani) (M.S.) during Rabi season of 2019-20. The exploration of genetically variable accession or genotypes is the key source of germplasm conservation and potential breeding material for the future use. The highly divergence group of cultivars provides an opportunity to breeders for developing superior and new varieties considering their quality traits for direct commercial utilization. Assessment of genetic diversity existing in and within germplasm groups for yield and its components to obtained superior recombinants which will helpful in understanding pattern of variation was performed utilizing the thirty six genotypes and four standard checks of chickpea replicated twice. To study the nature and magnitude of genetic divergence using Mahalanobis (1936) D2 statistics, phenotypic variances, coefficient of variation, heritability, genetic advance, correlation coefficient and path coefficient was estimated and cluster analysis was performed.

Keywords
Phenotypic, Genotypic, Path coefficient analysis, Chickpea

The chickpea seed is a good source of proteins and carbohydrate, which together constitute 80 % of the total dry weight of seed. Pulses occupy unique position in Indian Agriculture because of their characteristics of maintaining and restoring soil fertility, besides high nutritive value. Pulses restore soil fertility through biological nitrogen fixation with the help of symbiotic bacteria Rhizobium in roots. Hence it fixes the high amount of nitrogen through environment. Among the pulses, chickpea is important Rabi crop of India. It occupies the
first position among the pulses grown in the country with maximum average acreage and production.

India, a major pulse producing country, accounts roughly 33% of the total world production. Pulses are grown both during Kharif and Rabi seasons. Among the pulse, the chickpea is an important Rabi pulse crop of the India. Among all pulses chickpea contributes 36% area and 46% production in year 2017-2018. During 2017-2018 estimated area and production of chickpea in Maharashtra state is 18.92 lakh ha and 17.61 lakh tons respectively. In Maharashtra, the highest chickpea was grown on 19.29 lakh ha with the highest production of 19.41 lakh tones during 2016-17. The productivity was highest during 2016-2017 (1006kg/ha).

In India percentage of area is increased upto 10.82% during year 2017-18 as compared to previous year while percentage of area decreased by 4.28% in Maharashtra. Maharashtra is having 14.57% contribution in the area with 13.51% production share in the nation. Madhya Pradesh state is having the highest area of 35.91 lakh ha, production 45.89 lakh tons and productivity 1279 kg/ha during the year 2017-2018. During 2017-18, the area in Maharashtra was 20 lakh ha with production of 17.59 lakh tons and productivity is 882 kg/ha (Anonymous 2017).

In year 2019-20, India was having 106 lakh ha area with production of 111 lakh tons with productivity 1056 kg/ha while Maharashtra was having area 20.38 lakh ha with the production of 17.29 lakh tones and having productivity 848.55 kg/ha. Maharashtra occupying area about 19.22%, production 15.57%. While Marathwada having 10.59 lakh ha area with the production of 7.96 lakh tones with the productivity of 760.54 kg/ha (Anonymous, 2019-20).

Generally, plant breeders select the parents on the basis of phenotypic divergence, but for effective breeding, the knowledge of genetic diversity among the parents with respect to the particular characters which are to be improved is essential. Plant genetic resources or gene pool are the basis for global food security. They contain diversity of genetic material in traditional varieties, modern cultivars, currently cultivated varieties and crop wild relatives.

Mahalanobis’s (1936) reported that D2 statistics is a powerful tool for estimating the divergence between two populations. Many studies based on D2 technique also indicated that geographical isolation is not necessarily related to genetic diversity. It thus gives better idea about the magnitude of genetic divergence and is independent of size of sample and provides the basis for selection of parental lines for further breeding programme for improving particular character.

Genetic variation for traits is important in breeding programmes for selecting desirable genotypes from population. On the other hand, an analysis of the correlation between seed yield and yield components is essential for determining selection criteria of a particular character. Path coefficient analysis may useful to determine the direct effect of traits and their indirect effects on other traits.
In plant breeding, correlation coefficient analysis measures the mutual relationship between various variables and determines the component characters on which selection can be based for genetic improvement in yield. Correlation coefficient is a statistical measure which is used to find out the degree (strength) and direction of relationship between two or more variables. The genotypic and phenotypic paths are commonly estimated to determine yield contributing characters which are mostly useful for plant breeders and geneticists in selection of elite genotypes from diverse genetic population for further improvement.

Genetic diversity among parents, which is heritable, is a pre-requisite for any successful breeding programme. The proper choice of the parents in the breeding programme is very importance in further study. Generally plant breeder selects the parents on the basis of phenotypic divergence, but for effective breeding, the knowledge of genetic diversity amongst the parents with respect to the characters which are to be improved is essential. The association of one or more characters influenced by a large number of genes is elaborated statistically by correlation coefficients. Genotypic correlation coefficient provides a measure of genotypes conjugation between characters. The method of partitioning the correlation into direct and indirect effects by path analysis as suggested by Dewey and Lu (1959) and developed by Wright (1921).

The second step in path analysis is to prepare path diagram based on cause and effect relationship. In the present study, path diagram was prepared by taking yield as the effect i.e. function of various components like $X_1$, $X_2$, $X_3$ and these component showed following type of association with each other.

![Path Diagram](image)

In path diagram the yield is the result of $X_1$, $X_2$, $X_3$ ......$X_n$ and some other undefined.

**Experimental design**

Thirty six genotypes of chickpea along with four standard checks viz. Akash (BDNG-797), Digvijay, NBeG-47, JG (16) were evaluated in randomized block design with two replications during Rabi season of 2019-20. Each genotype was sown in four rows of 4 m length with spacing of 30 cm between rows and 10 cm within rows.

**Path coefficient analysis**

To establish a cause and effect relationship the first step used was to partition genotypic and phenotypic correlation coefficient into direct and indirect effects by path analysis as suggested by Dewey and Lu (1959) and developed by Wright (1921).

The present investigation entitled, Genetic Divergence Studies in Chickpea (*Cicer arietinum* L.) was conducted at Agricultural Research Station, Badnapur, during Rabi season of 2019-20.
factors designated by R. The double arrow lines indicated mutual association as measured by correlation coefficient. The single arrow represents direct influence as measured by path coefficient P_{ij}.

Path coefficients were obtained by solving a set of simultaneous equation of the form as per Dewey and Lu (1959).

\[ r_{ny} = P_{ny} + r_{n2}P_{2y} + r_{n3}P_{3y} + \ldots \]

Where,

- \( r_{ny} \) represents the correlation between one component and yield
- \( P_{ny} \) represents path coefficient between that character and yield
- \( r_{n2} \) represents correlation between that character and each of the other components in turn.

\[
\begin{pmatrix}
  r_{1y} \\
  r_{2y} \\
  \vdots
\end{pmatrix}
= \begin{pmatrix}
  r_{11} & r_{12} & \ldots & r_{1n} \\
  r_{21} & r_{22} & \ldots & r_{2n} \\
  \vdots & \vdots & \ddots & \vdots \\
  r_{n1} & r_{n2} & \ldots & r_{nn}
\end{pmatrix}
\begin{pmatrix}
  P_{1y} \\
  P_{2y} \\
  \vdots
\end{pmatrix}
\]

\[ r_{ny} = r_{n1}P_{1y} + r_{n2}P_{2y} + r_{n3}P_{3y} + \ldots \]

Where,

\[ r_{12} = r_{21} \]

\[ r_{1y} = \text{Correlation between one component character and seed yield} \]

The ‘B’ matrix was inverted \([B]^{-1}\) and path coefficients (P_{ij}) were obtained as,

\[ i.e. \quad P_{ij} = (B)^{-1}.A \]

The indirect effects of a particular character through other characters were obtained by multiplication of direct paths and particular correlation between these characters separately.

Indirect effects = \( r_{ij} \times P_{iy} \)

Where,

\[ i = 1 \text{ to } 9 \]
\[ j = 1 \text{ to } 9 \]
\[ P_{iy} = P_{1y}, P_{2y}, \ldots \ldots \ldots \ldots \ldots \ldots , P_{ny} \]

Path coefficient (P_{ij}), correlation coefficient (r_{ij}) and residual factors (R) were diagrammatically presented. The residual factor i.e. variation in yield unaccounted for by these associations was calculated with the following formula:

\[ \text{Residual factor (R)} = (1 - R^2) \]

Where,

\[ R^2 = P_{1y}r_{1y} + P_{2y}r_{2y} + \ldots \ldots \ldots \ldots + P_{ny}r_{ny} \]

\[ P_{1y}, P_{2y}, \ldots \ldots \ldots P_{ny} = \text{Direct path values} \]
\[ r_{1y}, r_{2y}, r_{ny} = \text{Correlation coefficient.} \]

**Results and Discussion**

To find out the direct and indirect contribution from each of the character towards seed yield per plant, path coefficient analysis was carried out. The phenotypic and genotypic correlation coefficients being more important are only partitioned to direct and indirect effects which are presented in Table 2 and 3. Phenotypic and genotypic path diagrams are given in figure 1.

**Direct effect**

Among all the components, number of pods per plant \((p=0.6197)\), exhibited the highest direct effect on seed yield followed by number seeds per pod \((p=0.3274)\), 100 seed weight \((p=0.2979)\), number of secondary branches per plant \((p=0.2839)\), primary branches \((p=0.0479)\) and harvest index \((p=0.0371)\) while plant height \((p=-0.0108)\),
days to maturity (p=-0.0505), days to 50% flowering (p=0.0888) recorded negative direct effect at phenotypic level.

At genotypic level days to 50% flowering (g=2.5584) exhibited the highest positive direct effect on seed yield followed by number of pods per plant (g=0.6068), 100 seed weight (g=0.3619), number of seeds per pod (g=0.3489) and harvest index (g=0.0337) while number of primary branches per plant (g=-0.119), plant height (g=-0.0379), initial plant stand (g=-0.1743), secondary branches per plant (g=-0.1784) and days to maturity (g=-0.1801) negative direct effect by genotypic level.

**Indirect effect**

**Initial plant stand**

Initial plant stand had significant negative phenotypic and genotypic correlation (p=-0.1535; g=-0.01743) with seed yield per plant and negative indirect effect through of number of pods per plant (p=-0.0021; g=-0.0129), number of secondary branches (p=-0.0026 g=0.0662) seeds per pod (p=-0.0033; g=0.0022), plant height (p=-0.0051; g=-0.0289), days to maturity (p=-0.0056; g=-0.0154), days to 50% flowering (g=-0.0007; g=-0.5366), harvest index (p=-0.0092; g=-0.0476), 100 seed weight (p=-0.0094; g=-0.0506).

**Days to 50% flowering**

Days to 50% flowering had significant negative phenotypic and positive genotypic correlation (p=−0.0888; g=2.5584) with seed yield per plant. It exhibited positive indirect effects through days to maturity (p=0.237), plant height (p=0.102), number of seeds per pod (p=0.0098), number of secondary branches (p=0.0038) positive indirect effect through harvest index (g=0.1050), initial plant stand (g=0.1275) and primary branches per plant (g=0.0057) at genotypic level. Negative indirect effect through of pods per plant (p=-0.0021; g=-0.0298), harvest index (p=-0.0075), initial plant stand (p=-0.0122), primary branches per plant (p=-0.0131) followed by 100 seed weight (p=-0.0236; g=-0.0632) at both phenotypic and genotypic level. Thus these indirect causal factors are to be considered during selection process for improving seed yield per plant.

**Days to maturity**

Days to maturity had negative direct phenotypic and genotypic correlation (p=-0.0505; g=-0.1804) with seed yield per plant. It exhibited positive indirect effects through days to 50% flowering (p=0.008; g=0.4951), number of seed per pod (p=0.0005; g=0.0163), plant height (p=0.0001; g=0.0055), and negative indirect effect through number of pods per plant (p=-0.0004; g=-0.0113), initial plant stand (p=-0.0003; g=-0.0109), harvest index (p=-0.0004; g=-0.01561), number of primary branches per plant (p=-0.0004; g=-0.0173) followed by number of secondary branches per plant (p=-0.0007; g=-0.0361), at both phenotypic and genotypic level in the decreasing order of their magnitude.

**Plant height**

Number of primary branches per plant showed negative direct phenotypic and genotypic correlation (p=-0.0108; g=0.0379) with seed yield per plant. It has positive indirect effect via initial plant stand (p=0.0040), 100 seed weight (p=0.0015), number of seeds per pod (p=0.0001) at phenotypic level and harvest index (p=0.00015; g=0.0015) at both phenotypic and genotypic level also show positive indirect effect through days to 50% flowering (g=0.0494), number of primary branches per
plant (g=0.0210), days to maturity (g=0.0036), number of secondary branches (g=0.0173) at genotypic level. Negative indirect effect through days to 50% flowering (p=-0.0047), days to maturity (p=-0.0018), number of secondary branches (p=-0.0099) at both phenotypic level in the decreasing order of their magnitude. Number of pods per plant (g=-0.0039), 100 seed weight (g=-0.0024) Followed by initial plant stand (g=-0.0134) at genotypic level of magnitude.

**Number of primary branches per plant**

Number of primary branches per plant had positive phenotypic correlation (p=0.0479) and negative genotypic correlation (g=-0.0119) with seed yield per plant. It showed positive indirect effects at both phenotypic and genotypic level through plant height (p=0.0132; g=0.123). Number of secondary branches per plant (p=0.0152), initial plant stand (p=0.0104), number of pods per plant (p=0.0061), number of seeds per pod (p=0.003) shows the positive indirect correlation at phenotypic level. 100 seed weight (g=0.0195), harvest index (g=0.013), days to 50% flowering (g=0.0120) positive indirect effect by genotypic correlation. It showed negative indirect effects at phenotypic level through days to maturity (p=-0.0053), days to 50% flowering (p=-0.0062), harvest index (p=-0.0076), 100 seed weight (p=-0.0119).

Fig. 1 Diagram showing the phenotypic path correlation of yield and its component characters of Chickpea

Number of secondary branches per plant

Number of secondary branches per plant had positive phenotypic correlation (p=0.2839) and Negative genotypic correlation (g=-0.1781) with seed yield per plant. It showed positive indirect effects through number of primary branches per plant (p=0.0955; g=0.0798), number of pods per plant (p=0.0716; g=0.0556), plant height (p=0.0630; g=0.0635), days to 50% flowering (p=0.0112; g=0.0125), number of seeds per pod (p=0.0015). It showed negative indirect effect through initial plant stand (-0.0131; g=-0.0252), harvest index (p=-0.0414; g=-0.30362) days to maturity (p=-0.0588; g=-0.0869), and 100 seed weight (p=-0.0602; g=0.1827) at phenotypic level and genotypic level.

Number of pods per plant

Number of pods per plant had positive phenotypic and genotypic correlation (p=0.6197; g=0.6068) with seed yield per plant. It displayed positive indirect effect through number of secondary branches per plant (p=0.2055; g=0.2004), number of seeds per pod (p=0.1444; g=0.1784), number of primary branches per plant (p=0.1101; g=0.1002) at phenotypic level and genotypic level. It showed negative indirect effect through plant height cm (p=-0.0259; g=-0.0521), days to maturity (p=-0.0288; g=-0.0976), initial plant stand (p=-0.0300; g=-0.0788), 100 seed weight (p=-0.1771; g=-0.1827) and harvest index (p=-0.2059; g=-0.2402). Days to 50% flowering (p=-0.0181) show negative indirect effect at phenotypic level.

Number of seeds per pod

Number of seeds per pod had positive phenotypic and genotypic correlation (p=0.3274; g=0.3489) with seed yield per plant. Number of pods per plant (p=0.0524; g=0.0706), days to maturity (p=0.0408; g=0.0562), days to 50% flowering (p=0.0303; g=0.5328), number of primary branches per plant (p=0.0213; g=0.0315) number of secondary branches per plant (p=0.0016)
showed positive indirect effect at both phenotypic and genotypic level. Days to maturity (g=0.0562) show positive indirect effect on genotypic level. Plant height (p=-0.0006; g=-0.0021), initial plant stand (p=-0.0175), 100 seed weight (p=-0.0220; g=-0.0279) and harvest index (p=-0.0417; g=0.0552) it show negative indirect effect at phenotypic level and genotypic level.

**100 seed weight**

100 seed weight had positive phenotypic and genotypic correlation (p=0.2979; g=0.0.3619) with seed yield per plant. It showed positive indirect effect through harvest index (p=0.1801; g=0.2393), days to maturity (p=0.0092; g=0.0422), at both phenotypic and genotypic level. And days to 50% flowering (g=1.5198) and show positive indirect level on genotypic level. Plant height (p=0.0219; g=-0.0300), number of seeds per pod (p=0.0481; g=0.0659), initial plant stand (p=0.1088; g=-0.2890) number of secondary branches per plant (p=0.1373; g=-0.1820), number of pods per plant (p=0.1391; g=-0.1709) showed negative indirect effect through both at phenotypic and genotypic level.

**Harvest index**

Harvest index had positive phenotypic and genotypic correlation (p=0.0371; g=0.0337) with seed yield per plant. It exhibited positive indirect effect through 100 seed weight (p=0.0562; g=0.0250) at phenotypic and genotypic level. Plant height (p=-0.0067; g=-0.0019), days to 50% flowering (p=-0.0157; g=-0.2638), days to maturity (p=-0.0267; g=-0.0132), number of seeds per pod (p=-0.0284; g=-0.0136), number of secondary branches per plant (p=-0.0294; g=-0.0128), initial plant stand (p=-0.0331; g=-0.0284), number of primary branches per plant (p=-0.0337; g=-0.0159) and number of pods per plant (p=-0.0510; g=-0.0235) show indirect negative effect at both phenotypic and genotypic level.

In conclusion the path coefficient analysis indicated that the characters viz., harvest index, number of pods per plant, 100 seed weight, number of secondary branches per plant, primary branches per plant and days to 50% flowering showed positive direct effect on seed yield. Hence, the selection of genotypes based on these characters as selection criterion would be helpful in improving the seed yield potential of chickpea.
