Density Functional Calculation of H₂O/CO₂/CH₄ for Oxygen-Containing Functional Groups in Coal Molecules

Dan Zhao and Xiaoqing Liu

ABSTRACT: To investigate the adsorption mechanism of H₂O, CO₂, and CH₄ molecules on oxygen-containing functional groups (OFGs) in coal molecules, quantum chemical density functional theory (DFT) simulations were performed to study the partial density of states and Mulliken bond layout of H₂O molecules bonded to different OFGs. The adsorption energy and Mulliken charge distribution of the H₂O, CO₂, and CH₄ molecules for each OFG were determined. The results showed that H₂O molecules form 2, 1, 1, and 1 hydrogen bonds with −COOH, −OH, −C=O, and −O−R groups, respectively. Double hydrogen bonds connected the H₂O molecules to −COOH with the smallest adsorption distances and highest Mulliken bond layout values, resulting in the strongest bonding between the H₂O molecules and −COOH. The most stable configuration for the adsorption of these molecules by the −OH group was when the O−H bond in the OFG served as a hydrogen bond donor and the O atom in the H₂O molecule served as a hydrogen bond acceptor. The order of the bonding strength between the OFGs and H₂O molecules was Ph−COOH > Ph−OH > Ph−C=O > Ph−O−R. The adsorption energy calculation results showed that H₂O molecules have a higher adsorption stability than CO₂ and CH₄ molecules. Compared with the −OH, −C=O, and −O−R groups, the −COOH group had a higher adsorption capacity for H₂O, CO₂, and CH₄ molecules. The adsorption stability of the CO₂ molecules for each OFG was higher than that of the CH₄ molecules. From the Mulliken charge layout, it was clear that after the adsorption of the H₂O molecules onto the OFGs, the O atoms in the OFGs tend to gain electrons, while the H atoms involved in bonding with the H₂O molecules tend to lose electrons. The formation of hydrogen bonds weakens the strength of the bonds in the H₂O molecule and OFGs, and thus, the bond lengths were elongated.

1. INTRODUCTION

The continuous exploitation of coal, oil, and natural gas could lead to the exhaustion of fossil-based energy sources. Fossil fuel usage is associated with the release of large amounts of greenhouse gases, such as CO₂ and CH₄, which threaten the ecological environment. Therefore, the development of cleaner, nonconventional energy sources is the way forward.

Coal bed methane (CBM) is a gas resource that is associated and symbiotic with coal. It is a clean, high-quality energy source (compared to coal) and a chemical raw material with CH₄ as the main component while containing certain amounts of CO₂ and N₂, with largely no pollutants after combustion (assuming CO₂ as a non-pollutant). Hence, CBM can be used as a clean energy source to improve the energy mix. The CO₂ emitted from the production processes and purified by adsorption, membrane separation, absorption, and low-temperature separation is injected into a coal seam to induce a competitive adsorption between CO₂ and CH₄, thereby effectively displacing CH₄ gas in the coal seam and realizing enhanced coal bed methane (ECBM) recovery. CO₂ carbon capture, utilization, and storage (CCUS) and CH₄ separation and utilization are feasible and effective ways to reduce the greenhouse effect. Hence, it is important to study the adsorption properties of CO₂ on coal surfaces to reduce greenhouse gas emissions.

The adsorption of gases on the surface of coal seams is influenced by the pressure, temperature, moisture content, surface functional groups, pore structure, and degree of coalification of the coal matrix, among which the surface functional groups have a particularly important influence in the case of medium and low-rank coals. In recent years, the density functional theory (DFT) and molecular dynamics (MD) simulations, as well as improvements made to computer hardware, have made quantum
theory and molecular simulation methods effective theoretical tools for studying the adsorption properties of gases in coal seams and for calculating surface interactions.\textsuperscript{20–23} Huo et al. investigated the adsorption strength of different oxygen-containing functional groups (OFGs) for \textit{H\textsubscript{2}O} molecules using the DFT, and based on the analysis of the electron density and potential energy density, the order of the capacity of four different OFGs to adsorb \textit{H\textsubscript{2}O} molecules was found to be Ph–C–O–OH > Ph–COOH > Ph–OH > Ph–CHO.\textsuperscript{24} Wang et al. studied the interaction between \textit{H\textsubscript{2}O} molecules and OFGs using the quantum chemical DFT and concluded that the order of the influence of the \textit{H\textsubscript{2}O} molecules on the adsorption stability of the OFGs was carboxyl group > phenolic hydroxyl group > aldehyde group > ether and that the OFGs could improve the wettability on the surface of coal molecules.\textsuperscript{25} Xiang et al. investigated the adsorption behavior of the binary component \textit{CH\textsubscript{4}}:\textit{CO\textsubscript{2}} (molar ratio of 1:1) using the grand canonical Monte Carlo (GCMC) method, and the results showed that the adsorption capacity for \textit{CO\textsubscript{2}} was significantly greater than that for \textit{CH\textsubscript{4}} at the same temperature and pressure, the competitive advantage was evident, and \textit{CO\textsubscript{2}} injection could help effectively displace \textit{CH\textsubscript{4}}.\textsuperscript{26} Xu et al. investigated the adsorption and desorption of \textit{CH\textsubscript{4}} and \textit{CO\textsubscript{2}} on a 4 × 4 carbon model using the DFT, and the results showed that \textit{CO\textsubscript{2}} had a higher adsorption stability than \textit{CH\textsubscript{4}} and that \textit{CO\textsubscript{2}} injection could promote the desorption of \textit{CH\textsubscript{4}}.\textsuperscript{27} Zhou et al. used the quantum chemical DFT to study the interaction between \textit{CH\textsubscript{4}} and \textit{H\textsubscript{2}O} on the surface of different grades of coal and concluded that a coal–\textit{H\textsubscript{2}O} system has a greater adsorption energy than a coal–\textit{CH\textsubscript{4}} system for coals of different maturities and that water injection could improve CBM recovery.\textsuperscript{28} Yu et al. calculated the competitive adsorption and self-diffusion of \textit{CH\textsubscript{4}}, \textit{CO\textsubscript{2}}, and \textit{\textit{H\textsubscript{2}O}} on the surface of low-rank coal vitrinite \textit{(C\textsubscript{214}H\textsubscript{180}O\textsubscript{24}N\textsubscript{2})} using GCMC and MD simulations.\textsuperscript{29} The results showed that in the \textit{CH\textsubscript{4}}/\textit{CO\textsubscript{2}}/\textit{H\textsubscript{2}O} = 1:1:1 ternary competitive system, the adsorption amount of the mirror mass group at the same temperature and pressure was in the order of \textit{H\textsubscript{2}O} > \textit{CO\textsubscript{2}} > \textit{CH\textsubscript{4}}, and the value of the self-diffusion coefficient was in the order of \textit{D}_{\textit{CH\textsubscript{4}}} > \textit{D}_{\textit{CO\textsubscript{2}}} > \textit{D}_{\textit{H\textsubscript{2}O}} in the saturated adsorption configuration. This shows that the adsorption capacity is highest for \textit{H\textsubscript{2}O} molecules and that injecting water into a coal seam can help improve CBM production. The adsorption effect of \textit{H\textsubscript{2}O} was better than that of \textit{CO\textsubscript{2}}, which could accelerate the recovery of coal seam gas.\textsuperscript{29}

Many simulations and calculations have been performed on the adsorption of \textit{H\textsubscript{2}O}, \textit{CO\textsubscript{2}}, \textit{CH\textsubscript{4}}, and other molecules on the surface of coal molecules;\textsuperscript{30–33} however, few studies have analyzed the adsorption of small molecules at the atomic and electronic levels. To investigate the adsorption behavior of small molecules of \textit{H\textsubscript{2}O}, \textit{CO\textsubscript{2}}, and \textit{CH\textsubscript{4}} on different OFGs (–COOH, –OH, –C–O, and –O–R) in the coal molecules, this study analyzed and compared the interactions between these molecules and each OFG on the surface of a coal model based on the DFT. Moreover, the adsorption mechanism was explored to provide a reference for studying the gas adsorption characteristics on the surface of coal molecules containing different OFGs and to provide theoretical support for the application of \textit{H\textsubscript{2}O}-ECBM and \textit{CO\textsubscript{2}}-ECBM.

2. CALCULATION METHOD

The optimization of the molecular models of OFGs, \textit{H\textsubscript{2}O}, \textit{CO\textsubscript{2}}, and \textit{CH\textsubscript{4}} and the calculation of the molecular properties in this study were conducted using the DS BIOVIA Materials Studio 2020 software. The geometric optimization of OFGs, \textit{H\textsubscript{2}O}, \textit{CO\textsubscript{2}}, and \textit{CH\textsubscript{4}} molecules and the calculation of the adsorption energy of small molecules in OFGs were done using the Dmol\textsuperscript{3} module. The maximum iteration for the geometric optimization was set to 500 to ensure convergence. The correlation function adopted for the electron exchange was the Perdew–Burke–Ernzerhof (PBE) functional based on generalized gradient approximation (GGA),\textsuperscript{34} the Grimme method was used for the DFT-D correction, DFT Semicore Pseudopot and double numeric with polarization basis set (DNP) was employed,\textsuperscript{35} the accuracy was set to Fine, unrestrict electron spins were considered, and symmetry was applied. The convergence accuracy of the self-consistent field was set to 1.0 × 10\textsuperscript{−6}, the maximum number of SCF cycles was set to 500, and the smearing value was set to 0.005 Å. An energy value of 1.0 × 10\textsuperscript{−4} Ha was set as the convergence criterion for the geometric optimization. The maximum force was set to 0.002 Ha/Å, and the maximum displacement was set to 0.005 Å.

The energy of the completely optimized stable adsorption configuration was optimized using the CASTEP module to calculate its partial density of states (PDOS),\textsuperscript{37} Mulliken bond layout, and electron density difference. Different stable adsorption configurations were optimized in periodic unit cells of 15 Å × 15 Å × 15 Å. The exchange correlation function and convergence standard were the same as those employed in the Dmol\textsuperscript{3} module, and ultra-soft pseudopotentials were used to describe the interaction between the electrons and ions.\textsuperscript{38} The smearing value used for the PDOS analysis was 0.2 eV. The electron density difference was calculated by defining the density difference for the \textit{H\textsubscript{2}O}, \textit{CO\textsubscript{2}}, and \textit{CH\textsubscript{4}} molecules in different adsorption configurations by Edit Sets, and the electron density difference graph was derived using Analysis.

The adsorption stability of \textit{H\textsubscript{2}O}, \textit{CO\textsubscript{2}}, and \textit{CH\textsubscript{4}} molecules on different OFG surfaces can be expressed in terms of the adsorption energy. If the adsorption energy is negative, the reaction is exothermic. The lower the value, the stronger and more stable the adsorption, and vice versa. The calculation formula for the adsorption energy is as follows:

\begin{equation}
\Delta E_{\text{ads}} = E_{A/B} - E_A - E_B
\end{equation}

where \(\Delta E_{\text{ads}}\) is the adsorption energy of each molecule on different OFG surfaces (kJ/mol); \(E_{A/B}\) is the total energy of different OFGs with each small molecule after adsorption (kJ/mol); \(E_A\) is the energy of different OFGs (kJ/mol); and \(E_B\) is the energy of different small molecules (\textit{H\textsubscript{2}O}, \textit{CO\textsubscript{2}}, and \textit{CH\textsubscript{4}}) (kJ/mol).

To comprehensively analyze the effect of the OFGs in the coal molecules on the adsorption of \textit{H\textsubscript{2}O}, \textit{CO\textsubscript{2}}, and \textit{CH\textsubscript{4}} molecules, 2 × 2 hexacyclic aromatic clusters \textit{(C\textsubscript{16}H\textsubscript{10})} were selected to simulate the surface of coal molecules during the quantum chemical calculations.\textsuperscript{39} The interactions between the OFGs, such as carboxyl (Ph–COOH), phenolic hydroxyl (Ph–OH), carbonyl (Ph–C═O), and ether (Ph–O–R) groups and the different molecules were calculated separately (where Ph═ denotes phenyl, and R− denotes alkyl).
3. RESULTS AND DISCUSSION

3.1. Hydrogen Bond Analysis. The most stable configuration of H₂O molecules for adsorption by different OFGs was used as an example to analyze the bonding properties. Figure 1 shows four adsorption configurations. As shown in Figure 1, the most stable adsorption positions of the H₂O molecules on the different OFGs are all above the OFG, and the initial configurations of the H₂O molecules are in the down form, except for the H₂O molecules at Ph−O−R, which are in the up form. The H₂O molecule forms 2, 1, 1, and 1 hydrogen bonds with −COOH, −OH, −C==O, and −O−R, respectively. The H₂O molecule forms a double hydrogen bond when adsorbed by −COOH with the shortest hydrogen bond length of 1.700 Å. In the adsorption by the −OH group, the O−H bond in the OFG as the hydrogen bond donor and the O atom in the H₂O molecule as the hydrogen bond acceptor is the most stable adsorption configuration, with a hydrogen bond length of 1.841 Å. In the adsorption by the −C==O and −O−R groups, the hydrogen bond lengths formed are 1.877 and 2.048 Å, respectively. The initial bond length of the H₂O molecule is 0.970 Å, and the initial bond angle is 103.749°. Table 1 presents the bond lengths and bond angles of the H₂O molecules at different OFG adsorption equilibria. Table 2 presents the bond lengths of the OFGs before and after the adsorption equilibria.

The bonding mechanism of the H₂O molecules with each OFG was further elucidated by calculating the PDOS. Figure 2a,b shows the PDOS of the H₂O molecule forming two hydrogen bonds with the Ph−COOH surface. Figure 2a,b shows the hydrogen bonds H₇₋₋Oₛ₁ between the H atom of the H₂O molecule and the O atom of the C==O bond in −COOH and the hydrogen bonds H₇₋₋Oₛ₉ between the H atom of the O−H bond in −COOH and the O atom of the H₂O molecule, respectively. The orbitals of Oₛ₁ and Oₛ₉ are mainly distributed in the valence band near the Fermi energy level, and the distribution is not evident in the conduction band, which is favorable for bonding. In Figure 2a,b, the H 1s orbital and O 2p orbital are bonded in the energy range of −9 to −3 eV, and the anti-bonds are bonded in the energy range of 4−13 eV, with evident resonance phenomena, indicating the formation of two hydrogen bonds on the surface of the H₂O molecules and Ph−COOH. Hydrogen bonds are formed by the interaction between the H 1s orbital and O 2p orbital. The hydrogen bond H₇₋₋Oₛ₉ is stronger than H₇₋₋Oₛ₁ owing to the stronger delocalization of H 1s in Figure 2b than in Figure 2a. Figure 2c−e shows that the −9 to −3 eV, H 1s orbital, and O 2p orbital are bonded and that the 4−13 eV, H 1 s orbital, and O 2 p orbital are anti-bonded. Corresponding to the hydrogen bond H₇₋₋Oₛ₉ between the H atom of the −OH group and the O atom in the H₂O molecule, the hydrogen bond H₇₋₋Oₛ₉ between the H atom of the H₂O molecule and the O atom in the −C==O group and the hydrogen bond H₇₋₋Oₛ₉ between the H atom of the H₂O molecule and the O atom in the −O−R group. From the off-domain nature of H 1s, as shown in Figure 2, it is clear that the order of the bonding strength between the OFGs and H₂O molecules is Ph−COOH > Ph−OH > Ph−C==O > Ph−O−R.

To quantify the bond strength of the H₂O molecules at different OFG sites, the Mulliken bond layout of the H₂O molecules adsorbed on the surfaces of different coal models was determined. Table 3 presents the results. Based on the calculation results, the average bond lengths of the H₂O molecules forming hydrogen bonds with different OFGs are 1.781, 1.841, 1.877, and 2.048 Å. The adsorption equilibrium distances are significantly lower than 3 Å, which is not near the covalent bond length (van der Waals forces act in the range of 3−5 Å). This shows that the adsorption mechanism of H₂O molecules on the OFGs is chemisorption. The Mulliken bond layouts of the H₂O molecules adsorbed at different OFG sites are in the order of Ph−COOH > Ph−OH > Ph−C==O >

| Ph−C==O         | C==Oₛ              | 1.231                  | 1.238                 |
| Ph−O−R          | Ph(C)==Oₛ          | 1.368                  | 1.374                 |
|                 | Oₛ−C(R)            | 1.428                  | 1.435                 |

**Table 3. Bond Length of OFGs before and after Adsorption Equilibrium**

| adsorption site | atomic relationship | d(before adsorption)/Å | d(after adsorption)/Å |
|-----------------|---------------------|------------------------|-----------------------|
| Ph−COOH         | C==Oₛ₁              | 1.233                  | 1.239                 |
|                 | C−Oₛ₁               | 1.369                  | 1.344                 |
|                 | Oₛ₁−Hₛ              | 0.980                  | 1.012                 |
| Ph−OH           | C−Oₛ               | 1.373                  | 1.362                 |
|                 | Oₛ−Hₛ              | 0.973                  | 0.989                 |
| Ph−C==O         | C==Oₛ              | 1.231                  | 1.238                 |
| Ph−O−R          | Ph(C)==Oₛ          | 1.368                  | 1.374                 |
|                 | Oₛ−C(R)            | 1.428                  | 1.435                 |

**Hₛ and Oₛ denote the H and O atoms of the OFG, respectively; Oₛ₁: the O atom of the C==O bond in −COOH; Oₛ₂: the O atom of the O−H bond in −COOH.**
The shorter the hydrogen bond length, the greater the Mulliken bond layout value, indicating stronger hydrogen bonds, a result consistent with the PDOS calculations of the hydrogen bond formation.

### 3.2. Adsorption Energy Calculation

Figure 3 shows the most stable adsorption configurations of the H$_2$O, CO$_2$, and CH$_4$ molecules for different OFGs. Table 4 shows the adsorption energies of the H$_2$O, CO$_2$, and CH$_4$ molecules for the OFGs. The results showed that the adsorption energies of the H$_2$O molecules for each OFG are significantly lower than those of the CO$_2$ and CH$_4$ molecules. The adsorption capacity is much greater than those of the CO$_2$ and CH$_4$ molecules; this is mainly attributed to the interaction between the H$_2$O molecules and each OFG via hydrogen bonding. The order of the strong and weak adsorption abilities of the H$_2$O molecules for different OFGs is Ph−COOH > Ph−OH > Ph−C=O > Ph−O−R, this order is in full agreement with the Mulliken bond layout order described above and also with the order of strong and weak adsorption capacity in the literature of Xia et al. and Gao et al. The adsorption energy of the H$_2$O molecules for Ph−COOH is much greater than that for the other OFGs because of the formation of double hydrogen bonds during the adsorption of the H$_2$O molecules by Ph−COOH, with an adsorption energy of $-70.474$ kJ/mol, which is close to the adsorption energy of $-69.250$ kJ/mol obtained by Xia et al. Gao et al. calculated the adsorption energy between a single H$_2$O molecule and the hydroxyl, carbonyl groups in lignite as $-43.140$ and $-38.240$ kJ/mol, respectively, which is closer to the results calculated in this paper. Both CO$_2$ and CH$_4$ are nonpolar molecules; however, CO$_2$ molecules have a strong polarizability and quadrupole moment, enabling them to easily interact with polar OFGs and exhibit significant electron transfer. The CH$_4$ molecule is an orthotetrahedral structure formed by averaging the energy and spatial orientation of one 2s orbital and three 2p orbitals; this structure is very stable and has less electron transfer when interacting with OFGs. The adsorption energy calculations of CO$_2$ and CH$_4$ molecules for each OFG show that the CO$_2$ molecules have a higher adsorption capacity than the CH$_4$ molecules. The order of the strong and weak adsorption capacities of the CO$_2$ molecules is Ph−COOH > Ph−C=O > Ph−OH > Ph−O−R, and the results are in agreement with
The order of the strong and weak adsorption abilities of the CH$_4$ molecules is Ph$-COOH > Ph-OH > Ph-O-R > Ph-C=O$. Comparing the adsorption energy magnitudes of the different molecules for each OFG, it can be found that the adsorption energy values of H$_2$O, CO$_2$, and CH$_4$ molecules, particularly H$_2$O molecules, for $-COOH$ were lower than those for the other OFGs, indicating that the adsorption ability is stronger on the $-COOH$ group.

### 3.3. Charge Analysis

The variation in the charge between the bonding atoms or interacting atoms when H$_2$O, CO$_2$, and CH$_4$ molecules were adsorbed on different OFG surfaces can be graphically represented by electron density difference diagrams. The charge transfer of different molecules adsorbed on each OFG surface can be represented visually using the Mulliken charge layout. Figure 4 shows the electron density difference diagrams of the H$_2$O, CO$_2$, and CH$_4$ molecules in each OFG adsorption system. In the figure, the negative value (blue area) indicates a decrease in the electron density before relative adsorption, and the darker the color, the greater the

| adsorption site | adsorption energy/E$_{ads}$ (kJ·mol$^{-1}$) |
|-----------------|------------------------------------------|
|                 | H$_2$O | CO$_2$ | CH$_4$ |
| Ph$-COOH$       | -70.474 | -13.437 | -10.142 |
| Ph-OH           | -49.089 | -12.259 | -8.197  |
| Ph-C=O          | -40.997 | -12.954 | -7.123  |
| Ph-O-R          | -32.344 | -10.681 | -7.391  |

**Figure 3.** Most stable adsorption configurations of H$_2$O, CO$_2$, and CH$_4$ molecules for different OFGs (white: H atom; red: O atom; gray: C atom).

**Table 4. Adsorption Energies of H$_2$O, CO$_2$, and CH$_4$ Molecules for Different OFGs**

*The values are given in kJ·mol$^{-1}$.*

---

...
decrease in the electron density; the positive value (red area) indicates an increase in the electron density before relative adsorption, and the darker the color, the greater the increase in the electron density. To clearly observe the electron density difference diagrams, the isosurface value for the H2O and CH4 molecules adsorbed on the OFG surface in the stable configuration was taken as 0.20 electron/Å³, and the isosurface value for the CO2 molecules adsorbed on the OFG surface in the stable configuration was taken as 0.05 electron/Å³. Tables 5−7 present the Mulliken charge layouts of the H2O, CO2, and CH4 molecules adsorbed on different OFG surfaces before and after adsorption equilibrium.

From Figure 4a−d and Table 5, it can be seen that the O−H bond in −COOH acts as a hydrogen bond donor and the O atom in the H2O molecule acts as a hydrogen bond acceptor; after adsorption, the H atom in −COOH loses 0.040 electrons, while the O atom in the H2O molecule gains 0.039 electrons. The O−H bond in the H2O molecule acts as a hydrogen bond donor, and the O atom in the C==O bond of −COOH acts as a hydrogen bond acceptor. After adsorption, the H atom in the H2O molecule loses 0.058 electrons, and the O atom in the C==O bond of −COOH gains 0.065 electrons, consistent with the electron density difference diagrams. In addition to the O atom in the C==O bond of COOH, the O atom in the O−H bond also gains electrons because of the strong electronegativity of the O atom on the OFG, which easily gains electrons, and the H atom in the H2O molecule is the main electron-losing atom. The formation of hydrogen bonds weakens the bonding strength between the H2O molecule and OFG. From Tables 1 and 2, it can be seen that d(C==O), d(O−H=Hs), and d(HW1,OW) in the H2O/Ph−COOH stable adsorption configuration elongate by 0.016, 0.032, and 0.022 Å, respectively, similar to the C==O bond and O−H bond elongation distances calculated by Gao et al.44 and the

|                 | .     |                              |                             |                     | H_{w2}| 0.249                        | 0.244                        | −0.005              |
| Ph−O−R          | O_s  | −0.462                        | −0.493                      | −0.031              | H_{w1}| 0.249                        | 0.287                        | 0.038               |
| Ph(C)           | 0.295                        | 0.282                       | −0.013              | O_w  | −0.499                       | −0.547                       | −0.048              |
| R(C)            | 0.013                        | −0.001                      | −0.014              | H_{w2}| 0.249                        | 0.254                        | 0.005               |
however, the bond length elongation is not evident in the stable adsorption configurations of H2O molecules from 103.749 to 104.683°, whereas in the H2O/Ph functional group an increase in the density of the II electron cloud on the benzene ring and a gain of 0.007 electrons. The O−H bond in Ph−OH acts as a hydrogen bond donor, and the O atom in the H2O molecule acts as a hydrogen bond acceptor. After adsorption, the H atom in the O−H bond loses 0.032 electrons, the O atom gains 0.028 electrons, and the H atom in the H2O molecule gains 0.013 electrons. In the H2O/Ph−OH stable adsorption configuration, d(O5,H5) and d(HW1,OW) elongate by 0.016 and 0.005 Å, respectively. The charge of the O atom in the H2O molecule changes less, whereas the charges of the two H atoms in the H2O molecule change significantly, 0.024 and 0.028, which increases the bond angle between the H2O molecules from 103.749 to 104.683°. In both the C==O and −O−R sites, O5 has a high electronegativity and easily gains electrons, and HW1 involved in the bond formation easily loses electrons, resulting in an increase in the O5 charge by 0.043 and 0.031 in −C==O and −O−R, respectively; however, the bond length elongation is not evident in −C==O and −O−R, both being 0.007 Å. The bond angle of the H2O molecule in the H2O/Ph−C==O adsorption configuration changes from 103.749 to 104.277°, whereas in the H2O/Ph−O−R adsorption configuration, the bond angle of the H2O molecule decreases from 103.749 to 102.946° due to the charge attraction of O5 to HW2.

As listed in Table 6, for the CO2 molecule in the Ph−COOH, Ph−OH, Ph−C==O, and Ph−O−R stable adsorption configurations, the O atom in the OFGs all gain electrons, −0.011, −0.017, −0.01, and −0.01 e, respectively, and the C atoms in CO2 all lose electrons, 0.016, 0.026, 0.02, and 0.02 e, while the two O atoms of CO2 gain −0.012, −0.027, −0.024, and −0.016 electrons, respectively. Figure 4e−h shows that the electron density difference diagrams are consistent with the results of the Mulliken atomic charge analysis. As shown in Table 7, the charge transfer is less when the CH4 molecule is adsorbed by different OFGs, and the center C atoms of the CH4 molecule all gain electrons, −0.028, −0.012, −0.009, and −0.009 e; the H atoms in the CH4 molecule all lose electrons; and the charges of the atoms in the different OFGs do not change significantly. The same consistency can be observed even in Figure 4i−l.

Combining the adsorption energy and charge analysis of the different small molecules on the coal model surface for each OFG, the more evident the charge transfer between the group atoms, and the order of the adsorption stability of the small molecules on each OFG is H2O > CO2 > CH4.

4. CONCLUSIONS

(1) The results of the PDOS and Mulliken bond layout analysis showed that H 1s orbitals and O 2p orbitals act on the OS1 and HW1 changes the bond angle of the H2O molecule from 103.749 to 104.957°. At the −OH site, the −OH functional group has an electron conjugation effect, leading to an increase in the density of the II electron cloud on the benzene ring and a gain of 0.007 electrons. The O−H bond in Ph−OH acts as a hydrogen bond donor, and the O atom in the H2O molecule acts as a hydrogen bond acceptor. After adsorption, the H atom in the O−H bond loses 0.032 electrons, the O atom gains 0.028 electrons, and the H atom in the H2O molecule gains 0.013 electrons. In the H2O/Ph−OH stable adsorption configuration, d(O5,H5) and d(HW1,OW) elongate by 0.016 and 0.005 Å, respectively. The charge of the O atom in the H2O molecule changes less, whereas the charges of the two H atoms in the H2O molecule change significantly, 0.024 and 0.028, which increases the bond angle between the H2O molecules from 103.749 to 104.683°. In both the −C==O and −O−R sites, O5 has a high electronegativity and easily gains electrons, and HW1 involved in the bond formation easily loses electrons, resulting in an increase in the O5 charge by 0.043 and 0.031 in −C==O and −O−R, respectively; however, the bond length elongation is not evident in −C==O and −O−R, both being 0.007 Å. The bond angle of the H2O molecule in the H2O/Ph−C==O adsorption configuration changes from 103.749 to 104.277°, whereas in the H2O/Ph−O−R adsorption configuration, the bond angle of the H2O molecule decreases from 103.749 to 102.946° due to the charge attraction of O5 to HW2.

aC: the C atom in CH4 molecule; H: all H atoms in the CH4 molecule.
interact to form hydrogen bonds. The average bond lengths of the $\text{H}_2\text{O}$ molecules forming hydrogen bonds with $-\text{COOH}$, $-\text{OH}$, $-\text{C}==\text{O}$, and $-\text{O}==\text{R}$ groups were 1.781, 1.841, 1.877, and 2.048 Å, respectively. Combining the numerical magnitude of the Mulliken bond layout, the delocalization of H 1s in PDOS, and the adsorption energy between the $\text{H}_2\text{O}$ molecules and different OFGs, the order of the bond strength between the $\text{H}_2\text{O}$ molecules and OFGs was found to be $\text{Ph}$–$\text{COOH}$ > $\text{Ph}$–$\text{OH}$ > $\text{Ph}$–$\text{C}==\text{O}$ > $\text{Ph}$–$\text{O}==\text{R}$.

(2) The results of the adsorption energy calculations for the different molecules confirmed the interaction between the $\text{H}_2\text{O}$ molecules and different OFGs via hydrogen bonding; hence, the adsorption stability of the $\text{H}_2\text{O}$ molecules for each OFG was higher than those of the $\text{CO}_2$ and $\text{CH}_4$ molecules. The adsorption stability of the $\text{H}_2\text{O}$ molecules for $\text{Ph}$–$\text{COOH}$ was greater than that for the other OFGs because of the formation of two hydrogen bonds between the $\text{H}_2\text{O}$ molecules and $-\text{COOH}$. Similarly, the adsorption stability of the $\text{CO}_2$ and $\text{CH}_4$ molecules for $\text{Ph}$–$\text{COOH}$ was greater than that for the other OFGs.

(3) The results of the Mulliken charge layout and electron density difference analysis of the different molecules showed that after the adsorption of the $\text{H}_2\text{O}$ molecules by the different OFGs, the O atoms in the OFGs easily gain electrons and that the H atoms involved in bonding with the $\text{H}_2\text{O}$ molecules easily lose electrons, resulting in different degrees of elongation of the bond between the OFGs and $\text{H}_2\text{O}$ molecules; the most evident elongation was of the $\text{O}$–$\text{H}$ bonds in the $-\text{COOH}$ groups at 0.032 Å. The difference in the adsorption configuration led to an increase in the bond angle of the $\text{H}_2\text{O}$ molecule in the $-\text{COOH}$, $-\text{OH}$, and $-\text{C}==\text{O}$ groups and a decrease in the case of the $-\text{O}==\text{R}$ group. After the adsorption of the $\text{CO}_2$ molecules by different OFGs, all the O atoms in the OFG gained electrons, and all the C atoms in the $\text{CO}_2$ molecules lost electrons. After the adsorption of the $\text{CH}_4$ molecules by different OFGs, all the C atoms at the center of the $\text{CH}_4$ molecules gained electrons, while all the H atoms in the $\text{CH}_4$ molecules lost electrons. The electron gained and lost by the different molecules were consistent with the electron density difference diagrams.

(4) OFGs are important factors affecting gas adsorption; the adsorption stability of different small molecules for each OFG was found to be $\text{H}_2\text{O} > \text{CO}_2 > \text{CH}_4$, indicating that $\text{H}_2\text{O}$ molecules have the highest adsorption capacity and that injecting water into the coal seam can improve the CBM yield; the adsorption effect of $\text{H}_2\text{O}$ was better than that of $\text{CO}_2$, which can help accelerate the recovery of coal seam gases.
