Cultural Aspects of Palliative Cancer Care in Iran

Sahar Fallahi, MSc; Maryam Rassouli, PhD, RN; Leila Khanali Mojen, PhD Candidate

School of Nursing and Midwifery, Shahid Beheshti University of Medical Sciences, Tehran, Iran

ABSTRACT

Palliative care is a human need, which is essential for patients with chronic disorders such as cancer, and aims to prevent and relieve pain and improve the quality of life (QoL) of patients and their families. Since culture is an important factor in predicting health behavior, it can be effective in providing these services. Thus, this review study has been conducted to assess the cultural aspects of palliative care in Iran. The findings were classified and provided based on the definition of palliative care on three major topics including early diagnosis, during treatment and disease period, and finally death and later. In the beginning of diagnosis, the most important element of palliative care is informing the disease to the patient and family. Disclosure of the disease in Iran is not culturally possible. The most important cultural barrier is cancer stigma in Iran, which affects the related measures such as screening diagnosis. The most important challenge in the treatment is pain management, which overshadowed factors such as cultural beliefs. Despite the challenges in the diagnosis and treatment of patients, which make the care difficult, the religious and spiritual context of Iranian people in the death and bereavement, as well as the strong family connections, are considered as a strong point that is helpful in the process of passing from the stage. According to the statement of the Union for International Cancer Control in 2008 based on “a better attitude toward cancer by 2020 and removing misconceptions about the disease”, the available cultural opportunities in the country can be considered as areas in need of strengthening. The negative attitudes and beliefs can be reformed by adopting strategies such as increasing the awareness of the community as the first strategy in changing the culture.

KEY WORDS: Palliative care; Culture; Iran; Cancer.

INTRODUCTION

Cancer is the third cause of death in Iran after heart disease and accidents.¹ According to global statistics of GLOBOCAN, more than 85,000 cases are reported and it is projected to have an ascending trend over the next decade due to increasing life expectancy and changing lifestyles. Considering the fact that this amount is estimated as much as 1,56,000 people by 2030,² it will become one of the major health problems in Iran.

Since cancer patients experience many difficulties in all aspects of their lives, providing a comprehensive system in the form of a supportive and palliative care is required to avoid the influence of the negative consequences of the disease and improve the quality of life (QoL) of patients.¹ Palliative care is the set of measures that aim to improve the QoL of patients and their families, in order to solve the problems caused by the disease.³ Palliative care is a holistic approach, which considers the physical, mental, social, and spiritual aspects of patients and their families and it is provided at the time of diagnosis and after death for their families.⁴ Presenting these services depends on various factors such as the economic, cultural and social status of every society.⁵ Therefore, providing palliative care regardless of cultural, anthropological, and even linguistic and semantic considerations not only do not reduce patients’ pain, but also do not work anymore to relieve it.⁶ Cultural factors overshadow their behavior by affecting attitudes toward health and disease and it is considered as an important factor in
treatment decisions especially in the end-of-life care. Iran is not excluded from this issue and the Iranian culture that will be dealt with in the following has a strong influence on such care. The fear of diagnosis leads to the lack of screening and the patient and the family would not be informed due to the concern of creating mental and spiritual distress in the patient. In such circumstances, it is clear that palliative care would not be possible easily. Even in the treatment stage, factors such as beliefs, cultural beliefs of different people with different religious and spiritual backgrounds and attitudes of individuals affect providing such services. Accordingly, this study was conducted to evaluate the cultural aspects affecting the palliative care at the time of diagnosis, during treatment, when dying, and after it in Iran.

Iranian Culture

Iran, with an area of 16,48,195 square kilometers and a population of nearly 75 million people and the official language of Persian and religion of Islam is located in the southwest of the continent of Asia and it is one of the Middle East countries. Iran's culture covers centuries of knowledge, wisdom, traditions, and customs. Thus, it can affect people’s life in many aspects of life. Iranian population, due to the passage of historical migrations has ethnic diversities, which has led to the formation of subcultures. The geographical location of Iran and the onslaught of different ethnic groups with different languages and religions during the past 3,000 years have led to the deployment of three Aryan language family, Sam (Arabic, Hebrew, Assyrian) and Urals, Altai (Turkish and Mongolian) as well as religions such as Zoroastrianism, Jewish, Christian and Islam in Iran whose impact can be observed in the health behaviors so that different beliefs about the pain and mourning rituals of different ethnic prove this. On the other hand, given that the majority of Iranians are Muslims in particular, Shi'a and the national and official language is Farsi (Persian), these factors play an important role in cultural homogeneity between the different ethnic groups in Iran. In fact, the Iranian culture is the result of Iranian ethnic minorities’ culture.

Analysis Method

This study aimed to find information related to the cultural dimension of palliative care in Iran, by searching SCOPUS, Proquest, Ovid, PubMed, ScienceDirect, Google scholar, and SID databases, with palliative care, cancer, chronic disease, and Iranian culture keywords. In addition, a wide range of data from journals, books, and publications were used on the sites. Finally, 53 relevant papers were selected (Figure 1). Inclusion criteria were, 1) papers were published between 2000 and 2016, 2) papers should have a variety of study methods, 3) papers should have full text, and 4) Papers are in Farsi and English.

RESULTS

260 papers were obtained. 53 papers were selected based on the research purposes and inclusion criteria and the results express and the findings indicated that palliative care is provided in the three stages of diagnosis, treatment, death, and after death that culture is known as an important factor in its presentation. These three stages have been studied separately in the following.

First Stage

Diagnosis: Palliative care begins with diagnosis, which challenges the cultural factors to provide in two stages of screening and telling the truth to the patient due to the stigma of cancer in this country.

Cancer screening: Screening is a method for early detection of cancer in people with the aim of reducing the spread of disease and deaths from it. In the developing countries, fear of cancer, lack of resources and lack of effective knowledge in avoiding screening for cancer are involved. The obstacles in Iran are factors such as fear of pain during mammography and its complications, high costs, lack of physician recommendation on mammography, the diagnosis of a serious illness and fear of rejection by their husbands, family members, and friends. In addition, Iran’s religious background was involved in this attitude so that belief in fate and the will of God lead to their reluctance to do preventive measures. The torment of women and shame due to religious reasons prevent them from visiting a doctor. Sometimes even self-examination is considered embarrassing and uncomfortable for them. It can be said that these behaviors are rooted in individuals’ attitudes and they are affected by Iranian culture so that the result of the study on Iranian immigrant women in America was known as the most important factor of screening refusal.
Telling the truth: Telling the truth in the medical profession is to provide the necessary information to enable the patient to make informed decisions about medical care and other aspects of life and informing him/her of the situation in which he/she is.14 5 to 66% of doctors believe that revealing the diagnosis of cancer and its prognosis is essential for the patient,13 while 37% of cancer patients in Iran are unaware of their disease diagnosis and 93% are unaware of their disease prognosis.15 In Western societies, “individual possession principle” has confirmed telling the truth to the patient, but in Eastern societies “lack of harm principle” has a higher priority than the individual possession. Given the centrality of the family in these communities, truth is concealed.17 In some cultures such as the culture of the communities in the Middle East and especially Iran, hiding the diagnosis and prognosis of cancer patients is not uncommon. Even, the disclosure of cancer may be considered as a rude, disrespectful, and damaging action. Some cultures believe that speaking about the incurable disease, death, and end-life-care would become a reality.18 In Iran, people equate cancer with death, and they still have not broken the taboo.19 This has caused that most of the people even doctors rarely use the word of “cancer” in their speaking and they mostly use “illness” as an alternative.16 For this reason, the truth of disease is concealed in Iran and doctors say the disease diagnose to a family member.19 Although, studies have shown that, in most cases, this is done at the request of the family20 because they believe that revealing the truth to the patient would lose hope and create additional distress.19 Some studies also showed that patients who do not know their disease have better life quality.21 Therefore, it can be said that the disease is highly considered as a family event rather than an individual event.22 For this reason, patients in Iran are primarily unaware of their diagnosis or they are the last one who becomes aware indirectly like seeing the folder, discussion with other patients, starting treatment such as chemotherapy, etc.2 However, the important point is whether the patients have a desire to know the truth or not? Several studies have shown that about 79 to 98% of patients want to know the diagnosis of their disease.23

The lack of formal training for doctors and nurses to deliver bad news to tell the information to patients with incurable diseases such as cancer can lead to psychological complications, especially anxiety and depression. Due to the taboo of cancer in Iran, if the news is informed in an inappropriate manner, the patients and their families will never forgive the treatment team and this is done properly, they will forget the treatment team.24

Cancer stigma: Stigma is the understanding and attitude of individuals from an unreasonably social judgment about a disease, which is highly influenced by the culture of that society. Factors such as imminent death, fear of symptoms and treatment, false beliefs regarding God’s punishment have made cancer a stigma,25 which is interpreted differently by the required conditions of society and public opinion. It is also effective on the interaction of people with cancer patients, the patients’ attitude to their illness, and their response so that fear of stigma can be a barrier to disclose a cancer diagnosis.26 In Iran, most people avoid to disclose their diagnosis due to avoid attracting others’ sympathy, their curiosity, and the fear of losing connections. Even in cases, women hide their disease due to the fear of family members’ concerns, changing their role of parents and spouses, the stigma of cancer and its legacy for the future of their children, and fear of losing job and they cause delay in starting treatment. Although, other beliefs including self-treatment, traditional medicine, and attention to others’ recommendation cause delay in treatment, but the main reason is the cultural fields and stigma of cancer in the country.27 In the field of cancer prevention, fear of stigma is a major obstacle in self-examination, screening, and delays in identification of cancer symptoms.26

The Second Stage

Treatment: Palliative care in this stage is mostly focused on managing symptoms such as pain and supporting families because pain is a common symptom at this stage and taking drugs is an important factor in developing these services. Thus, this stage has discussed the cultural factors affecting pain management.

Pain and its management: Pain is an individual, subjective, and unique cultural experience and many factors have an impact on its experience that culture is one of them. Pain control is so important in the care of patients that the American Pain Society (APS) has introduced it as the 5th vital sign.28 Pain in patients with cancer appears following primary tumor, metastasis tumor, radiation therapy, chemotherapy or surgery and not only is influenced by biochemical factors, but also is influenced by psychological and social factors. Pain created the most discomfort in cancer patients and it is seen in approximately 50-70% of these patients.29 Uncontrolled pains in cancer are one of the causes that push patients toward suicide.30 Therefore, pain and its control are one of the major challenges that culture has a significant role in it.32 Pain management is a response individuals’ reaction to pain, which depends on individual beliefs and occurs in the form of behaviors such as drug seeking or no pain relief. On the other hand, understanding patients’ beliefs requires good communication, which one of the care challenges in Iran33 and educational, managerial, organizational, and cultural factors are implicated in it.34 On the other hand, different languages and dialects in Iran and the country’s religious principles because of the low relationship between men and women have doubled the problem.35

Religious and spiritual beliefs are decisive as an integral part of the culture in understanding and managing pain and they are known as a positive strategy for coping with pain. In Iranian mysticism, which is the origin of teachings of Islam, there are certain interpretations of pain and despite the emphasis on alleviating the pain and analgesia healthcare services, in some cases, not only people do not look for drug and treatment, but also seek voluntary pain because they consider the pain as a treatment and value.35 From the religious view, pain and
focusing on the spiritual and religious aspects of palliative care. The cultural context is crucial for understanding the needs and preferences of patients and their families. In Iran, cultural beliefs and practices play a significant role in how patients and families approach end-of-life care. For instance, there is a strong emphasis on avoiding the mention of death and discussing it as 'passing' rather than 'dying.' This is partly due to the fear of the unknown and the anxiety associated with death.

**Cultural Beliefs and Practices**

In Iran, cultural beliefs around death are deeply rooted in Islamic teachings. The focus is on preparing the soul for天堂 (Heaven) and ensuring a peaceful transition. There is a strong belief in the power of faith and the importance of prayer. Many Iranians believe that the soul is immortal and that after death, the spirit continues to exist in a spiritual realm.

In terms of practices, there is a belief in the importance of funeral rituals and the role of the family in providing comfort and support for the dying. The family is often involved in decision-making and is expected to carry out the dying wishes of the patient. This includes considerations such as the place of death and the method of palliative care. Unlike Western countries, there is a greater acceptance and readiness to address the dying process in Iran, due to the cultural emphasis on the importance of death and the need to support the family in facing this challenge.

**Challenges and Opportunities**

Despite these cultural advantages, there are also challenges in implementing effective palliative care in Iran. One of the main challenges is the lack of trained healthcare providers in palliative care. There is a need for more education and training programs to ensure that healthcare providers are equipped to handle the complexities of end-of-life care. Additionally, there is a need for more research to understand the specific needs and preferences of patients and their families in Iran, and to develop culturally sensitive care plans.

In conclusion, the cultural context in Iran plays a significant role in shaping the approach to palliative care. While there are challenges, the cultural emphasis on faith, family support, and end-of-life rituals provides a foundation for effective palliative care. By understanding these cultural beliefs and practices, healthcare providers can better support patients and families in their journey through the final stages of life.
in the country that can be improved by strategies so that Daher et al. introduced education as an important component in changing the culture. Therefore, the available cultural opportunities in the country can be considered as areas in need of strengthening. The negative attitudes and beliefs can be reformed by adopting strategies such as increasing community awareness as the first economic strategy in changing the culture in the form of public education and the importance of early screening in cooperation with charities, using media, training in schools as well as holding cancer campaign by the Ministry of Health, Medical Treatment and Education on the World Cancer Day.
