Abstract. Pairs of SUSY partner Hamiltonians are studied which are interrelated by usual (linear) or polynomial supersymmetry. Assuming the model of one of the Hamiltonians as exactly solvable with known propagator, expressions for propagators of partner models are derived. The corresponding general results are applied to “a particle in a box”, the Harmonic oscillator and a free particle (i.e. to transparent potentials).

submitted to: \textit{J. Phys. A: Math. Theor.}

1. Introduction

The space-time evolution of a quantum mechanical system is governed by its Schrödinger equation and in its most complete form it is encoded in the propagator. The propagator defines the probability amplitude for a particle to move from one point of the space to another in a given time. Similar to propagators in relativistic field theories, it provides a global picture of the causal structure of a quantum system which goes beyond the information contained in a single wave function. Moreover, it plays the essential role in solving the probability related Cauchy problem of Quantum Mechanics (QM).

The vast literature on QM propagators, summarized e.g. in \cite{1}, lists mainly explicit expressions of propagators for stationary Schrödinger equations in one space dimension which are reducible to hypergeometric differential equations (DEs) or their confluent forms. This is in strong contrast to the available methods of supersymmetric Quantum Mechanics (SUSY QM) \cite{2,3} which usually lead to much broader classes of exactly solvable Schrödinger equations with solutions in particular expressible in terms of linear combinations of hypergeometric functions (see e.g. \cite{4}). From the structure of the SUSY induced relations between superpartner Hamiltonians it is clear that via the corresponding Schrödinger equations these relations should extend to relations between the associated propagators. The main goal of the present paper is to analyze these relations between SUSY partner propagators and to reshape them into user friendly general recipes for the construction of new propagator classes. Our interest in such new exact propagators is less motivated by their mere existence or their technical subtleties, but rather it is in their applicability to concrete physical problems (see e.g. \cite{5}) and here especially to models with well-tailored new properties and to setups.
which up to now were not related to SUSY techniques at all (see e.g. [6]). In order to derive the corresponding technical tools we concentrate in this paper on the general approach which allows to establish the link between the propagators of any two SUSY partner Hamiltonians.

Our main idea is the following. For a given Hamiltonian $h_0$, whose Schrödinger equation as a second order differential equation is exactly solvable, the general solutions of the Schrödinger equation of its SUSY partner Hamiltonian $h_N$ can be explicitly constructed. Knowing the relations between the solutions of the Schrödinger equations for $h_0$ and $h_N$ one can expect to derive transformation operators relating the associated propagators. At a first glance, this approach seems to be technically trivial. But when one recalls that the calculation of a closed expression for a propagator is usually more difficult than the derivation of a corresponding wave function, one may expect the problem to be connected with rather nontrivial technical subtleties. Moreover, if one wants to establish the explicit link between the propagators one may imagine that sometimes the problem may even become unsolvable.

Probably the first indication that the problem may have a solution was given by Jauslin [7] who constructed a general integral transformation scheme simultaneously for Schrödinger equations and for heat equations, but who didn’t provide a discussion of convergency and divergency of the derived expressions. For the sake of convergency he applied his technique to the heat-equation-type Fokker-Planck equation only. In general, this result may be extended via Wick rotation to propagators for Schrödinger equations of a free particle and a particle moving through transparent potentials. But the question of convergency and with it the question of solvability remains to be clarified. Another indication that the problem may be solvable has been provided by Refs [8, 9] where a similar model has been analyzed at the level of Green functions of stationary Schrödinger equations. In the present paper we carefully analyze the problem along the ideas first announced in [10].

The material is organized as follows. In the next section 2, we briefly recall some main facts and notations from SUSY QM necessary for our subsequent analysis and we sketch the definition of the propagator. Section 3 is devoted to the basic tool of our approach — the interrelation between propagators for models with partner Hamiltonians which are linked by first-order SUSY transformations. In Section 4 we generalize these results to polynomial supersymmetry. The general technique developed in these sections is afterwards used in section 5 to derive the propagators for SUSY partner models of “a particle in a box”, of the Harmonic oscillator and of the free particle (i.e. for models with transparent potentials). Section 6 concludes the paper.

2. Preliminaries

The subject of our analysis will be a polynomial generalization\(^1\) of the simplest two-component system of Witten’s non-relativistic supersymmetric quantum mechanics [12, 2, 3] described by the Schrödinger equation

\[
(iI\partial_t - H)\Psi(x, t) = 0 \quad x \in (a, b)
\]  

\(^1\) For a recent review see e.g. [11].
where $H$ is a diagonal super-Hamiltonian consisting of the two super-partners $h_0$ and $h_N$ as components

$$H = \begin{pmatrix} h_0 & 0 \\ 0 & h_N \end{pmatrix} \quad h_{0,N} = -\partial_x^2 + V_{0,N}(x).$$

The interval $(a, b)$ may be both finite or infinite. For simplicity we restrict our consideration to a stationary setup with $h_0$ and $h_N$ not explicitly depending on time so that the evolution equation reduces via standard substitution $\Psi(x, t) = \Psi(x)e^{-iEt}$ and properly chosen boundary conditions to the spectral problem

$$H\Psi = E\Psi.$$  

The time evolution of the system may be described in terms of a corresponding propagator.

Furthermore, we assume that the partner Hamiltonians $h_0$ and $h_N$ are intertwined by an $N$th-order differential operator $L$ with the following properties:

1. **Intertwining relations**
   $$Lh_0 = h_NL \quad h_0L^+ = L^+h_N$$

2. **Factorization rule**
   $$L^+L = P_N(h_0) \quad LL^+ = P_N(h_N)$$
   $$P_N(x) = (x - \alpha_0) \ldots (x - \alpha_{N-1})$$
   $$\text{Im}(\alpha_i) = 0 \quad \alpha_i \neq \alpha_k \neq i \quad i, k = 0, \ldots, N - 1.$$  

Here, the adjoint operation is understood in the sense of Laplace (i.e. as formally adjoint with the property $\partial_x^+ = -\partial_x$, $(AB)^+ = B^+A^+$ and $i^+ = -i$) and the roots $\alpha_i$ of the polynomial $P_N$ play the role of factorization constants. For simplicity we assume that the polynomial $P_N$ has only simple roots. The intertwining relations together with the factorization rule can be represented in terms of the polynomial super-algebra

$$Q^2 = (Q^+)^2 = 0 \quad [Q, H] = [Q^+, H] = 0 \quad QQ^+ + Q^+Q = P_N(H)$$

with nilpotent super-charges

$$Q = \begin{pmatrix} 0 & 0 \\ L & 0 \end{pmatrix} \quad Q^+ = \begin{pmatrix} 0 & L^+ \\ 0 & 0 \end{pmatrix}.$$  

Although the component Hamiltonians $h_0$ and $h_N$ enter the super-Hamiltonian in an algebraically symmetric way, we consider $h_0$ as given Hamiltonian with known spectral properties and $h_N$ as derived Hamiltonian with still undefined spectrum. More precisely we assume $V_0(x)$ to be real-valued, continuous and bounded from below\(^2\) so that the differential expression $h_0 = -\partial_x^2 + V_0(x)$ defines a Sturm-Liouville operator which is symmetric with respect to the usual $\mathcal{L}^2(a, b)$ inner product. The corresponding functions $\psi \in \mathcal{L}^2(a, b)$ are additionally assumed sufficiently smooth\(^3\), e.g. $\psi \in C^2(a, b)$, over the interval $(a, b) \subseteq \mathbb{R}$. Moreover, we assume Dirichlet boundary conditions (BCs) for the bound state eigenfunctions of $h_0$, i.e a domain

$$\mathcal{D}(h_0) := \{ \psi : \psi \in \mathcal{L}^2(a, b) \cap C^2(a, b), \psi(a) = \psi(b) = 0 \}$$

(see, e.g. [13]) and the

---

\(^2\)We assume the potential $V_0(x)$ bounded from below and short ranged, because we restrict our attention here to models with a finite number of bound states only. For spectral problems on the half-line a repulsive singularity at the origin not stronger than $t(\ell+1)x^{-2}$, $\ell = 0, 1, \ldots$ is possible.

\(^3\)As usual, $C^2(a, b)$ denotes the space of twice continuously differentiable functions.
operator $h_0$ itself being at least essentially self-adjoint (with a closure that we denote by the same symbol $h_0$). As usual, eigenfunctions which correspond to the continuous spectrum of $h_0$ are supposed to have an oscillating asymptotic behavior at spatial infinity. Concentrating on physically relevant cases we restrict our attention to the following three types of setups:

(i): The interval $(a, b)$ is finite $|a|, |b| < \infty$ so that $h_0$ has a non-degenerate purely discrete spectrum (see e.g. [15]).

(ii): For spectral problems on the half-line $(a = 0, b = \infty)$ we consider so called scattering (or short-ranged) potentials which decrease at infinity faster than any finite power of $x$ and have a continuous spectrum filling the positive semi-axis and a finite number of discrete levels; the whole spectrum is non-degenerate.

(iii): For spectral problems on the whole real line, $(a = -\infty, b = \infty)$, we consider confining as well as scattering potentials. Confining potentials produce purely discrete non-degenerate spectra (see e.g. [15]), whereas scattering potentials lead to two-fold degenerate continuous spectra filling the whole real line and to a finite number of non-degenerate discrete levels (see e.g. [15]).

Everywhere in the text we choose real-valued solutions of the differential equation $(h_0 - E)\psi = 0$. This is always possible since $V_0(x)$ is supposed to be a real-valued function and we always restrict ourselves to real values of the parameter $E$.

The intertwiner $L$ is completely described by a set of $N$ transformation functions $u_n(x)$, which may be both “physical” and “unphysical”\footnote{By “physical” solutions we mean solutions belonging to the domain $\mathcal{D}(h_0) = \{\psi : \psi \in L^2(a, b), \psi(a) = \psi(b) = 0\}$. All solutions $\psi \notin \mathcal{D}(h_0)$ corresponding to a spectral parameter $E$ outside the continuous spectrum are interpreted as “unphysical”. In the present paper, eigenfunctions corresponding to the continuous spectrum are not used as transformation functions and, although physically meaningful, we excluded them from our classification scheme of “physical” and “unphysical” solutions.} solutions of the stationary Schrödinger equation with $h_0$ as Hamiltonian:

$$h_0 u_n = \alpha_n u_n \quad n = 0, \ldots, N - 1.$$  

In our case of a polynomial $P_N(x)$ with simple roots (i.e. $\alpha_i \neq \alpha_k$) the action of the intertwiner $L$ on a function $f$ is given by the Crum-Krein formula [17] [18]

$$L f = \frac{W(u_0, u_1, \ldots, u_{N-1}, f)}{W(u_0, u_1, \ldots, u_{N-1})}$$

with $W$ denoting the Wronskian

$$W = W(u_0, u_1, \ldots, u_{N-1}) = \begin{vmatrix} u_0 & u_1 & \cdots & u_{N-1} \\ u_0' & u_1' & \cdots & u_{N-1}' \\ \vdots & \vdots & \ddots & \vdots \\ u_0^{(N-1)} & u_1^{(N-1)} & \cdots & u_{N-1}^{(N-1)} \end{vmatrix}.$$  

It links the solutions $\phi$ and $\psi$ of the Schrödinger equations with $h_N$ and $h_0$ as Hamiltonians by the relation $\phi = L \psi$. In particular, for $N = 1$ (a first-order transformation)\footnote{By “physical” solutions we mean solutions belonging to the domain $\mathcal{D}(h_0) = \{\psi : \psi \in L^2(a, b), \psi(a) = \psi(b) = 0\}$. All solutions $\psi \notin \mathcal{D}(h_0)$ corresponding to a spectral parameter $E$ outside the continuous spectrum are interpreted as “unphysical”. In the present paper, eigenfunctions corresponding to the continuous spectrum are not used as transformation functions and, although physically meaningful, we excluded them from our classification scheme of “physical” and “unphysical” solutions.} reads

$$\phi = L f = (-u_0 x / u_0 + \partial_x) f = \frac{W(u_0, f)}{u_0}$$

with $W(u_0) \equiv u_0$. Furthermore, the determinant structure [7] of the operator $L$ leads to the immediate implication that it has a nontrivial kernel space $\text{Ker}L$ spanned by the set of transformation functions $u_n$:

$$\text{Ker}L = \text{span}\{u_0, \ldots, u_{N-1}\} \quad \dim(\text{Ker}L) = \dim(\text{Ker}L^+) = N.$$
Exact propagators for SUSY partners

The solutions $v_n$ of the equation $h_N v_n = \alpha_n v_n$ are elements of the kernel space of the adjoint operator $L^+$ and can be obtained as:

$$v_n = \frac{W_n(u_0, u_1, \ldots, u_{N-1})}{W(u_0, u_1, \ldots, u_{N-1})} \quad n = 0, \ldots, N - 1$$  \hspace{1cm} (10)

$$Ker L^+ = \text{span}\{v_0, \ldots, v_{N-1}\}$$

where $W_n$ denotes the Wronskian built as a determinant of the $(N-1) \times (N-1)$ matrix with the unRelated column omitted $W_n = W(u_0, u_1, \ldots, u_{n-1}, u_{n+1}, \ldots, u_{N-1})$. The potential $V_N$ of the Hamiltonian $h_N$ can be expressed as:

$$V_N = V_0 - 2 \ln W(u_0, u_1, \ldots, u_{N-1})$$ \hspace{1cm} (11)

In general, it is not excluded that the transformation operator $L$ may move a solution of $h_0$ out of $\mathcal{H}_0 = L^2(a, b)$ thus transforming a physical solution of $h_0$ into an unphysical solution of $h_N$. Moreover the inverse scenario is also possible, i.e. $L$ may transform an unphysical solution of $h_0$ into a physical solution of $h_N$. In such cases the point spectrum of $h_N$ will differ from that of $h_0$. Subsequently, we will concentrate on mild transformations $L$, which leave most of the original spectrum invariant with exception of a finite number of spectral points — a characteristic feature of differential intertwining operators $L$ leaving the boundary behavior of the solutions of the Schrödinger equation unchanged. Recently in [19] a conjecture has been proven, which was originally formulated in [20] and which states that any $N$th-order mild differential transformation $L$ can be constructed as a superposition from only first- and second-order mild transformations. In this case it is possible to show [3] that for problems formulated over the whole $\mathbb{R}$ (for infinite values of $a$ and $b$) $V_N$ behaves asymptotically like $V_0$. Therefore the operator $h_N$ is also essentially self-adjoint and "lives" in the same Hilbert space $\mathcal{H}$ as $h_0$. Moreover, since the point spectrum of the self-adjoint Sturm-Liouville problems that we consider is non-degenerate there is no way to create a new discrete level at the position of an already existing discrete level and by this means to increase the geometric multiplicity of that level.

According to [18] the necessary condition for an $N$th-order transformation to produce an essentially self-adjoint operator $h_N$ is:

$$(E - \alpha_0) \ldots (E - \alpha_{N-1}) \geq 0 \quad \forall E \in \text{spec}(h_0).$$ \hspace{1cm} (12)

This criterion ensures the mildness of the transformation $L$ leading only to changes in maximally $N$ spectral points (of the point spectrum). Specifically, the spectrum of $h_N$ may contain $p$ points more and $q$ points less than $\text{spec}(h_0)$, where necessarily $p + q \leq N$.

In the present paper we will consider the following possibilities.

\textsuperscript{5)} See also \textsuperscript{A.11} in \textsuperscript{Appendix A}.

\textsuperscript{6)} This is in contrast to SUSY intertwined non-self-adjoint operators $h_0$, $h_2$ for which a second-order intertwining $L$ can map two distinct discrete levels of $h_0$ into a second-order Jordan block of $h_2$, i.e. an eigenvalue of geometric multiplicity one and algebraic multiplicity two (for the details see Ref. [21]).

\textsuperscript{7)} The basic idea can be understood as signature preservation of Hilbert space metrics, i.e. $\forall E$ belonging to the point spectrum of $h_0$ the eigenfunctions $\psi_E$ with $||\psi_E||^2 = \langle \psi_E, \psi_E \rangle > 0$ should map into corresponding eigenfunctions $\phi_E$ of $h_N$ with $||\phi_E||^2 = ||L\psi_E||^2 = \langle \psi_E, L^+ L \psi_E \rangle = \langle \psi_E, P_N(h_0) \psi_E \rangle \geq 0$ what via \textsuperscript{6)} implies \textsuperscript{13}. Here, the equality takes place for those $\psi_E$ for which the point $E$ does not belong to the spectrum of $h_N$, i.e. if $P_N(E) = 0$ and $\phi_E = L \psi_E \equiv 0$. A more detailed analysis of corresponding sufficient conditions for spectral problems on the whole real line in case of scattering potentials and of confining potentials is given in [23].
• The spectrum of $h_0$ is a subset of the spectrum of $h_N$. A new energy level may be created in the spectrum of $h_N$ if and only if the corresponding transformation function $u(x)$ is such that $1/u(x) \in \mathcal{D}(h_N)$, i.e., in particular, that $1/u(x)$ is $L^2$-integrable and satisfies the Dirichlet BCs.

• The spectrum of $h_N$ is a subset of the spectrum of $h_0$. An energy level may be removed from the spectrum of $h_0$ if and only if the corresponding transformation function $u(x)$ coincides with the $h_0$-eigenfunction of this level, i.e. when $u(x)$ satisfies the Dirichlet BCs.

• The spectrum of $h_0$ coincides with the spectrum of $h_N$. In this case non of the transformation functions $u_l(x)$ nor $1/u_l(x)$ should be physical, i.e. satisfy Dirichlet BCs on both ends of the interval $(a,b)$. This property should be fulfilled for all transformation functions $u_l(x)$ from which the transformation operator is built.

In all cases we assume that the transformation functions $\{u_l(x)\}_{l=1}^M$ are linearly independent one from the other and their Wronskian $W(u_1, \ldots, u_M)$ does not vanish $\forall x \in (a,b)$.

In the remainder of this section, we briefly recall some basic properties of quantum mechanical propagators. Once, the super-Hamiltonian (2) is diagonal it suffices to restrict to one-component (scalar) propagators.

It is well known that the propagator $K(x,y,t)$ of a non-stationary Schrödinger equation contains the complete information about the space-time behavior of the wave function $\Psi(x,t)$ evolving from an initial configuration $\Psi(x,0) = \Psi_0(x)$ solving in this way the probability related Cauchy problem of QM. The propagator (integration kernel) satisfies a differential equation with Dirac delta function as initial condition

$$[i\partial_t - h(x)]K(x,y,t) = 0 \quad K(x,y;0) = \delta(x-y).$$

(13)

For non-dissipative systems, like in our case, the propagator $K(x,y,t)$ can be interpreted as coordinate representation of the unitary evolution operator $U(t)$:

$$K(x,y,t) = \langle x|U(t)|y \rangle,$$

where unitarity implies the symmetry $K^*(x,y;-t) = K(y,x;t)$.

Subsequently, we will mainly work with a spectral decomposition of propagators in terms of complete basis sets of eigenfunctions

$$K(x,y;t) = \sum_{n=0}^{N_p} \psi_n(x,t)\psi_n^*(y) + \int_{-\infty}^{\infty} dk \psi_k(x,t)\psi_k^*(y)$$

(14)

where summation over the point spectrum and integration over the continuous (essential) spectrum are understood. By SUSY-transformations we will only induce changes in the point spectrum of $h_0$ so that, for simplicity, we will work with decompositions over discrete sets of basis functions (corresponding to point spectra) keeping in mind that extensions to the continuous spectrum are straight forward.

It is clear that the defining equation for the propagator of the non-stationary Schrödinger equation with super-Hamiltonian (2) can be trivially decomposed as

$$[iI\partial_t - H]K(x,y;t) = 0 \quad K = \begin{bmatrix} K_0(x,y;t) & 0 \\ 0 & K_N(x,y;t) \end{bmatrix}$$

$$K(x,y;0) = I\delta(x-y).$$
3. Propagators related by first-order intertwiners

In this section we study the structure of propagators interrelated by first-order SUSY transformations. Such SUSY transformations are generated from a single function $u(x)$ and they act as basic building blocks in chain representations of higher-order intertwiners. Although any $N$th-order intertwiner may be represented as a chain of first order intertwiners [3], one has to distinguish between chains which are completely reducible within a given Hilbert space $\mathcal{H}$ [22] and chains which are partially or completely irreducible in $\mathcal{H}$. Complete reducibility means that apart from $h_0$ and $h_N$ also all intermediate first-order SUSY related Hamiltonians $h_k$, $k \neq 0, N$ are self-adjoint or essentially self-adjoint in the same Hilbert space $\mathcal{H}$. In case of irreducible chains [9] several or all intermediate Hamiltonians are non-self-adjoint in $\mathcal{H}$. Below both chain types will play a role. We note that chain representations lead to extremely simplified transformation rules for higher-order intertwined propagators and allow for very efficient calculation techniques (see subsection 4.2 below).

According to (7) a first-order intertwiner has the form

$$L_x = -u'(x)/u(x) + \partial_x \quad h_0 u = \alpha u.$$  

Due to $E - \alpha \geq 0$ (see (12)) and depending on the concrete form of the function $u(x)$ the intertwiner $L$ may result in the following three types of relations between the spectra of the Hamiltonians $h_0$ and $h_1$ (see, e.g., [2]):

(i) for $\alpha = E_0$ and $u = \psi_0$ the ground state level $E_0$ of $h_0$ is removed from the spectrum of $h_1$,

(ii) $h_1$ has a new and deeper ground state level $E_{-1} = \alpha < E_0$ than $h_0$,

(iii) the spectra of $h_1$ and $h_0$ completely coincide ($\alpha < E_0$).

In order to create a potential $V_1(x)$ which is nonsingular on the whole interval $(a, b)$ one should choose $u(x)$ such that the function $u(x)$ coincides with the ground state eigenfunction $u(x) = \psi_0(x)$. In the cases (ii) and (iii) the nodelessness should be ensured by an appropriate choice of $u(x)$, a choice which is always possible because of the ‘oscillation’ theorem (see e.g. [16]). In case (iii) it implies $\alpha < E_0$.

Introducing the Green function

$$G_0(x, y; E) = \sum_{m=0}^{\infty} \frac{\psi_m(z)\psi_m(y)}{E_m - E}$$

(15)

of the stationary $h_0$–Schrödinger equation at fixed energy $E$ [9] (see, e.g. [22]) and its “regularized” version

$$\tilde{G}_0(z, y, E_0) = \sum_{m=1}^{\infty} \frac{\psi_m(x)\psi_m(y)}{E_m - E_0} = \lim_{E \to E_0} \left[ G_0(z, y, E) - \frac{\psi_0(x)\psi_0(y)}{E_0 - E} \right]$$

the corresponding structural relations for the propagators can be summarized in the following

**Theorem 1.** The propagators $K_1(x, y; t)$ and $K_0(x, y; t)$ of non-stationary Schrödinger equations with SUSY intertwined Hamiltonians $h_1$ and $h_0$ are interrelated with each other and with the Green functions $G_0(x, y; E)$ and $\tilde{G}_0(z, y, E_0)$ in the

---

8) For a careful analysis of different kinds of irreducible transformations we refer to [19].

9) We assume that $h_0$ has a purely discrete spectrum. As it was already stated in the Preliminaries, a generalization to the continuous spectrum is straightforward.
Exact propagators for SUSY partners

following way:
Type (i) relation
\[ K_1(x, y, t) = L_x L_y \int_a^b K_0(x, z, t) \tilde{G}_0(z, y, E_0) dz. \] (16)

Type (ii) relation
\[ K_1(x, y, t) = L_x L_y \int_a^b K_0(x, z, t) G_0(z, y, \alpha) dz + \phi_{-1}(x) \phi_{-1}(y) e^{-i \alpha t}. \] (17)

Type (iii) relation
\[ K_1(x, y, t) = L_x L_y \int_a^b K_0(x, z, t) G_0(z, y, \alpha) dz. \] (18)

Proof. We start from the type (ii) relation and represent the propagator \( K_1(x, y; t) \) in terms of the basis functions \( \phi_m(x, t) \) of the Hamiltonian \( h_1 \) (cf. [14]). We note that the explicit time-independence of \( h_1 \) implies a factorization \( \phi_m(x, t) = \phi_m(x) \exp(-i E_m t) \) with \( \phi_m(x) \) purely real-valued. Expressing \( \phi_m \) in terms of the corresponding wave functions of the Hamiltonian \( h_0 \), \( \phi_m = N_m \psi_m \) with \( N_m = (E - \alpha)^{-1/2} \) a normalization constant (see, e.g. [2]), we arrive at

\[ K_1(x, y, t) = \sum_{m=-1}^\infty \phi_m(x) \phi_m(y) e^{-i E_m t}. \]

Modulo a normalization factor \( N \), the wave function \( \phi_{-1} \) of the new ground state is proportional to the inverse power of the transformation function \( u(x) \), \( \phi_{-1} = N / u(x) \).

It remains to express the time-dependent phase factor in terms of the propagator. This can be easily done using the evident property of the bound state solutions of the Schrödinger equation

\[ \int_a^b K_0(x, z, t) \psi_m(z) dz = \psi_m(x) e^{-i E_m t} \] (19)

so that the previous equation reads

\[ K_1(x, y, t) = L_x L_y \int_{-\infty}^\infty K_0(x, z, t) \sum_{m=0}^\infty \frac{\psi_m(z) \psi_m(y)}{E_m - \alpha} dz + \phi_{-1}(x) \phi_{-1}(y) e^{-i \alpha t}. \] (20)

The sum in this relation can be identified as the Green function \( \tilde{G}_0 \). Due to \( E_m - \alpha > 0, \forall E_m \in \text{spec}(h_0) \) this Green function is regular \( \forall E_m \) and the proof for type (ii) transformations is complete.

The proof for type (i) and (iii) transformations follows the same scheme. The formally regularized Green function \( \tilde{G}_0(x, y, E_0) \) in (i) results from the fact that the ground state with energy \( E_0 \) is not present in the spectrum of \( h_1 \) so that a sum \( \sum_{m>0} \) appears and the ground state contribution has to be subtracted from \( G_0(x, y, \alpha = E_0) \). In case of a type (iii) transformation a sum \( \sum_{m=0}^\infty \) over the complete set of eigenfunctions appears in [20] and no new state occurs. \( \blacksquare \)
We conclude this section by reshaping relation (16) for the propagator of a system with removed original ground state, i.e. of a type (i) transformed system. The corresponding result can be formulated as

**Theorem 2.** For transformations with \( u(x) = \psi_0(x) \) the propagator \( K_1(x,y;t) \) of the resulting system can be represented as

\[
K_1(x,y;t) = -\frac{1}{u(y)} L_x \int_a^y K_0(x,z;t)u(z)dz = \frac{1}{u(y)} L_x \int_y^b K_0(x,z;t)u(z)dz.
\]  

(21)

First of all we recall that \( \psi_0(x) \) being the ground state function of \( h_0 \) satisfies the zero boundary conditions. To facilitate the proof of Theorem 2 we need the following two lemmas.

**Lemma 1.** \( L_y \lim_{E \to E_0} \left( G_0(z,y,E) - \frac{\psi_0(z)\psi_0(y)}{E_0 - E} \right) = \lim_{E \to E_0} L_y G_0(z,y,E). \)

_Proof._ This result follows from the explicit representation of \( G_0(z,y,E) \) in terms of basis functions. On the one hand, it holds

\[
L_y \lim_{E \to E_0} \left( G_0(z,y,E) - \frac{\psi_0(z)\psi_0(y)}{E_0 - E} \right) = \sum_{n=1}^\infty \frac{\psi_n(z)L_y \psi_n(y)}{E_n - E_0}
\]

whereas on the other hand the kernel property (annihilation) of the ground state \( L\psi_0 = 0 \) gives

\[
\lim_{E \to E_0} (L_y G_0(z,y,E)) = \lim_{E \to E_0} \left( \sum_{n=1}^\infty \frac{\psi_n(z)L_y \psi_n(y)}{E_n - E_0} \right) = \sum_{n=1}^\infty \frac{\psi_n(z)L_y \psi_n(y)}{E_n - E_0}.
\]

**Lemma 2.** Let \( f_i(x,E) \) and \( f_r(x,E) \) satisfy the Schrödinger equation

\[
h_0f(x,E) := -f''(x,E) + V_0(x)f(x,E) = Ef(x,E) \quad x \in (a,b)
\]

(22)

and boundary conditions

\[
f_l(a,E) = 0 \quad f_r(b,E) = 0.
\]

(23)

Let also \( E = E_0 \) be the ground state level of \( h_0 \) with \( \psi_0(x) \) as the ground state function (we assume that \( h_0 \) has at least one discrete level) then

\[
\lim_{E \to E_0} \frac{f_i(x,E)L_y f_r(y,E)}{W(f_l,f_i)} = -\frac{\psi_0(x) \int_a^b \psi_0^2(z)dz}{\psi_0(y) \int_a^b \psi_0^2(z)dz}
\]

(24)

\[
\lim_{E \to E_0} \frac{f_r(x,E)L_y f_l(y,E)}{W(f_r,f_l)} = \frac{\psi_0(x) \int_a^b \psi_0^2(z)dz}{\psi_0(y) \int_a^b \psi_0^2(z)dz}
\]

(25)

where \( L_y = -u'(y)/u(y) + \partial_y \) with \( u(y) \equiv \psi_0(y) \).

_Proof._ First we note that according to (9) \( L_y f_r(y,E) = W(u,f_r)/u \). Next, since both \( u = \psi_0 \) and \( f_r \) satisfy the same Schrödinger equation (22) it holds \( W'(u,f_r) = (E_0 - E)uf_r \) and hence

\[
W(u,f_r) = (E - E_0) \int_y^b u(z)f_r(z,E)dz
\]

(26)

\[
\int_a^b \psi_0^2(z)dz
\]
where we have used the property $W(u, f_r)_{y=b} = 0$ which follows from the BCs for $u$ and $f_r$. Via (26) we find

$$L_y f_r(y, E) = \frac{E - E_0}{u(y)} \int_y^b u(z) f_r(z, E) dz$$

(27)

and hence

$$L_y f_r(y, E) \frac{W(f_r, f_l)}{W(f_r, f_l)} = \frac{E - E_0}{f_l(b, E)} \int_y^b u(z) f_r(z, E) dz$$

(28)

where it has been used that the Wronskian $W(f_r, f_l) = f_r(x, E)f_l'(x, E) - f_l(x, E)f_r'(x, E)$ is $x$-independent and can be calculated at $x = b$ where $f_r(b, E) = 0$. Since the spectrum of $h_0$ is non-degenerate, the ground state function is unique up to an arbitrary constant factor and, hence, $u(x) = \psi_0(x)$, $f_r(x, E_0)$ and $f_l(x, E_0)$ have to be proportional to each other $f_r, f_l(x, E_0) = C_{r,l} u(x)$ (29)

and for $E \to E_0$ only the first fraction in (28) remains undetermined. The l’Hospital rule gives for this limit

$$\lim_{E \to E_0} \frac{E - E_0}{f_l(b, E)} = \frac{1}{f_l(b, E_0)}$$

(30)

where the dot denotes the derivative with respect to $E$. Making use of (30) and

$$\dot{f}_l(b, E_0)f_l'(b, E) = \int_a^b f_l^2(z, E_0) dz$$

(31)

(which we prove below) relation (28) yields

$$\lim_{E \to E_0} \frac{f_l(x, E)L_y f_r(y, E)}{W(f_r, f_l)} = -f_l(x, E_0)f_r'(b, E_0) \int_y^b u(z) f_r(z, E_0) dz$$

(32)

and via (29) it leads to the result (24). The proof of (25) follows the same lines with evident changes.

Finally, it remains to derive equation (31). This is easily accomplished by multiplying Schrödinger equation (22) for $f = f_l(x, E)$ by $\dot{f}_l(x, E)$, its derivative with respect to $E$ by $f = f_l(x, E)$, and integrating their difference over the interval $(a, b)$. The intermediate result

$$\int_a^b f_l^2(x, E) dx$$

$$= \dot{f}_l(a, E)f_l(a, E) - \int_a^b f_l(a, E)\dot{f}_l(a, E) - \dot{f}_l(b, E)f_l(b, E) + f_l'(b, E)\dot{f}_l(b, E)$$

(33)

reduces to (31) via BC (23) and its derivative with respect to $E$ (what cancels the first two terms) and the limit $E = E_0$, its implication (29) and the BC for $u(x)$. ☐
Explicitly acting with the differential operator $L$ whereas via Lemma 1 the intertwiner $L$ the second argument of the functions $K_{1\rightarrow r}$ has been omitted for notational simplicity. Explicitly acting with the differential operator $L_y$ on the integrals with variable $y$–boundary yields

$$K_1(x,y,t) = L_x \int_x^y K_0(x,z,t) \lim_{E \to E_0} \left[ \frac{f_l(x)f_r(y)}{W(f_r,f_l)} \Theta(y-z) - \frac{\psi_0(z)\psi_0(y)}{E_0 - E} \right] dz$$

where the step functions can be resolved to give

$$K_1(x,y,t) = L_x \int_x^y K_0(x,z,t) \lim_{E \to E_0} \left[ \frac{f_l(x)f_r(y)}{W(f_r,f_l)} - \frac{\psi_0(z)\psi_0(y)}{E_0 - E} \right] dz$$

The second argument of the functions $f_{l,r}$ has been omitted for notational simplicity. Explicitly acting with the differential operator $L_y$ on the integrals with variable $y$–boundary yields

$$K_1(x,y,t) = L_x \int_x^y K_0(x,z,t) \lim_{E \to E_0} \left[ \frac{f_l(x)f_r(y)}{W(f_r,f_l)} - \frac{\psi_0(z)\psi_0(y)}{E_0 - E} \right] dz$$

whereas via Lemma 2 the intertwiner $L_y$ and the limit $\lim_{E \to E_0}$ can be interchanged to give

$$K_1(x,y,t) =$$

$$L_x \left\{ \int_x^y K_0(x,z,t) \lim_{E \to E_0} \frac{f_l(x)L_yf_r(y)}{W(f_r,f_l)} dz + \int_y^b K_0(x,z,t) \lim_{E \to E_0} \frac{f_r(x)L_yf_l(y)}{W(f_r,f_l)} dz \right\}$$

Application of Lemma 2 leads to

$$K_1(x,y,t) = \frac{L_x}{\psi_0(y) \int_a^b \psi_0^2(q) dq} \left\{ -\int_y^b \psi_0^2(q) dq \int_a^y K_0(x,z,t) \psi_0(z) dz \right\}$$

$$+ \int_a^y \psi_0^2(q) dq \int_y^b K_0(x,z,t) \psi_0(z) dz \right\}$$

which we further reshape by expressing the integral with respect to $q$ over the interval $(y,b)$ by the difference of two integrals over the intervals $(a,b)$ and $(a,y)$. Substitution of $\psi_0 = u$ in the first term results in

$$K_1(x,y,t) = \frac{1}{u(y)} L_x \int_x^y K_0(x,z,t)u(z) dz$$

$$+ \frac{1}{\psi_0(y) \int_a^b \psi_0^2(q) dq} \int_y^b \psi_0^2(q) dq \int_a^y K_0(x,z,t) \psi_0(z) dz .$$

The very last integral is nothing but the ground state stationary wave function $\psi_0(x,t) = u(x)\exp(-iE_0t)$. Therefore, since $L_xu(x) = 0$, we obtain the first equality
in (21). The second equality results from applying a similar transformation to the second term in (37).

The following remarks are in order. First we have to note that the integral representation (21) is only valid in case of first-order SUSY transformations which remove the ground state level. If one wants to create a level in a problem on the whole real line one has to use a transformation function $u(x)$ which diverges for $x \to \pm \infty$ ensuring in this way the normalizability and Dirichlet BCs of the new ground state wave function $\phi_{-1}(x) \propto 1/u(x)$. An attempt to calculate the propagator $K_1$ via (21) would usually lead to a divergent integral. The correct approach is to use (17) in this case. Jauslin [7] using a different procedure obtained the same result (21) both for removing and creating a level, but he completely ignored questions of convergence or divergence of the corresponding integrals. In concrete calculations he avoided divergent integrals by considering the heat equation only.

4. Higher order transformations

4.1. Addition of new levels

Let us consider an $N$th-order ($N = 2, 3, \ldots$) polynomial supersymmetry corresponding to the appearance of $N$ additional levels in the spectrum of $h_N$ compared to the spectrum of $h_0$. In this case new levels may appear both below the ground state energy of $h_0$ (reducible supersymmetry) and between any two neighbor levels of $h_0$ (irreducible supersymmetry, see e.g. [20]). The propagator for the transformed equation can be found in the following way. We develop $K_N(x, y; t)$ over the complete orthonormal set $\{\phi_m(x, t)\}$ of eigenfunctions of $h_N$ and express all $\phi_m$ with eigenvalues already contained in the spectrum of $h_0$ in terms of $\psi_m$, i.e. $\phi_m = N_m L \psi_m$. The normalization constants $N_m$ for transformations fulfilling condition (12) have the form [3]:

$$N_m = [(E - \alpha_0)(E - \alpha_1) \ldots (E - \alpha_{N-1})]^{-1/2}.$$

All other eigenfunctions of $h_N$ which correspond to new levels and which are not contained in $\text{spec}(h_0)$ we keep untouched. This yields

$$K_N(x, y, t) = L_x L_y \sum_{m=0}^{\infty} \frac{\psi_m(x)\psi_m(y)}{(E_m - \alpha_0) \ldots (E_m - \alpha_{N-1})} e^{-iE_m t} + \sum_{n=0}^{N-1} \phi_n(x)\phi_n(y)e^{-i\alpha_n t}.$$

Here we interchanged the derivative operators present in $L_{x,y}$ and the summation. This interchange is justified because the propagators are understood not as a usual functions but as generalized functions [24] (which, in particular, may be regular, i.e. defined with the help of locally integrable functions). It remains to express $\psi_m(x)e^{-iE_m t}$ with the help of (19) in terms of $K_0(x, z, t)$, to make use of the identity

$$\prod_{n=0}^{N-1} \frac{1}{E - \alpha_n} = \prod_{n=0}^{N-1} \frac{1}{\alpha_j - \alpha_n} \frac{1}{E - \alpha_n}$$

and to represent the sum over $m$ in terms of the Green function $G_0(z, y, \alpha_n)$. As a result, one arrives at

$$K_N(x, y, t) = L_x L_y \sum_{n=0}^{\infty} \left( \prod_{j=0, j \neq n}^{N-1} \frac{1}{\alpha_j - \alpha_n} \right) \int_{-\infty}^{\infty} K_0(x, z, t)G_0(z, y, \alpha_n)dz.$$
Exact propagators for SUSY partners

\[ \sum_{n=0}^{N-1} \phi_n(x) \phi_n(y) e^{-i\alpha n t}. \] (39)

4.2. Removal of levels

In this section we need information on the intermediate transformation steps of Nth-order SUSY-transformations which goes beyond that presented in section 2. Therefore we start with a more detailed description of the transformation operators and solutions of the Schrödinger equation at each transformation step.

Let us consider a chain of N first-order transformations

\[ h_N \leftarrow h_{N-1} \leftarrow \ldots \leftarrow h_1 \leftarrow h_0 \]

built from operators \( L_{k+1,k} \) which intertwine neighbor Hamiltonians \( h_k \) and \( h_{k+1} \) as \( L_{k+1,k} h_k = h_{k+1} L_{k+1,k} \). We assume all Hamiltonians \( h_k, k = 0,\ldots,N \) self-adjoint or essentially self-adjoint in the same Hilbert space \( \mathcal{H} \) so that the SUSY-transformation chain itself is completely reducible. Furthermore, we assume that at each transformation step the ground state of the corresponding Hamiltonian is removed. This means that after \( N \) linear SUSY-transformations the first \( N \) states of the \( h_0 \)-system are removed and the \( N+1 \)st state of \( h_0 \) maps into the ground state of \( h_N \). In our analysis these first \( N+1 \) states of \( h_0 \) will play a crucial role and we denote them by \( u_{0,n}, n = 0,\ldots,N \). Furthermore, we use a numbering for the solutions \( u_{k,n} \) of the Schrödinger equations of the SUSY-chain Hamiltonians \( h_k, k = 0,\ldots,N \) which is “synchronized” with the level numbering of \( h_0 \), meaning that a function \( u_{k,n} \) is related to the spectral parameter \( E_n \). We have to distinguish between physical solutions, which correspond to the existing bound states of \( h_k \) and which have indices \( n = k,\ldots,N \), and unphysical auxiliary solutions \( u_{k,n} \) with \( n = 0,\ldots,k-1 \) which we construct below. The ground state eigenfunction of a Hamiltonian \( h_k \) is given by \( u_{k,k} \) and for \( k < N \) it is annihilated by the SUSY-intertwiner \( L_{k+1,k} \)

\[ L_{k+1,k} u_{k,k} = 0. \]

The bound state functions \( u_{k+1,n}, n = k+1,\ldots,N \) of \( h_{k+1} \) may be obtained by acting with the SUSY-intertwiner

\[ L_{k+1,k} = -u_{k,k,x} / u_{k,k} + \partial_x \quad L_{k+1,k} f = \frac{W(u_{k,k},f)}{u_{k,k}} \] (40)

on the corresponding eigenfunctions of \( h_k \)

\[ L_{k+1,k} u_{k,n} = u_{k+1,n} \quad n = k+1,\ldots,N. \]

Next, we note that the chain of \( k, \( k = 2,\ldots,N \) first-order transformations is equivalent to a single \( k \)th-order transformation \( L \) generated by the transformation functions \( u_{0,0}, u_{0,1},\ldots,u_{0,k-1} \). Furthermore, the transformation operators obey the composition rules

\[ L_{k+1,k} L_{k,l} = L_{k+1,l} \quad l = 0,\ldots,k-1 \quad k = 1,\ldots,N-1 \] (41)

so that, e.g., the second-order transformation operator \( L_{k+2,k} \) intertwines the Hamiltonians \( h_k \) and \( h_{k+2} \)

\[ L_{k+2,k} h_k = h_{k+2} L_{k+2,k} \quad k = 0,\ldots,N-2. \]

The \( N \)th-order transformation operator \( L_{N,0} \) is then inductively defined as \( L_{N,0} = L_{N,N-1} L_{N-1,0} \). Obviously, it annihilates the \( N \) lowest states of the original Hamiltonian \( h_0 \), i.e. \( u_{0,0},\ldots,u_{0,N-1} \in \text{Ker}L_{N,0} \).
As further ingredient for the derivation of the propagator-mapping we need the set of unphysical auxiliary functions \( u_{N,n} \), \( n = 0, \ldots, N - 1 \). We construct them as \( u_{N,n} = L_{N,0} \tilde{u}_{0,n} \), where the functions \( \tilde{u}_{0,n} \) are the unphysical solutions of the \( h_0 \)-Schrödinger equation at energies \( E_n \) which are linearly independent from the eigenfunctions \( u_{0,n} \). Normalizing \( \tilde{u}_{0,n} \) by the condition \( W(u_{0,n}, \tilde{u}_{0,n}) = 1 \) and integrating this Wronskian gives

\[
\tilde{u}_{0,n}(x) = u_{0,n}(x) \int_{x_0}^{x} \frac{dy}{u_{0,n}^2(y)}
\]

and finally

\[
u_{N,n}(x) = L_{N,0}u_{0,n}(x) \int_{x_0}^{x} \frac{dy}{u_{0,n}^2(y)} \quad n = 0, \ldots, N - 1.
\] (42)

In Appendix A we show that

\[
u_{N,n} = C_{N,n} \frac{W_n(u_0, \ldots, u_{N-1})}{W(u_0, \ldots, u_{N-1})}
\] (43)

\[
C_{N,n} = (E_{N-1} - E_n)(E_{N-2} - E_n) \cdots (E_{n+1} - E_n) \quad n = 0, \ldots, N - 2
\]

\[
u_{N,N-1} = \frac{W_{N-1}(u_0, \ldots, u_{N-1})}{W(u_0, \ldots, u_{N-1})} = \frac{W(u_0, \ldots, u_{N-2})}{W(u_0, \ldots, u_{N-1})}.
\] (44)

The ground state function of \( h_N \) is obtained by acting with \( L_{N,0} \) on the \( N \)th excited state of \( h_0 \):

\[
u_{N,N} = L_{N,0}u_{0,N} = \frac{W(u_{0,0}, \ldots, u_{0,N})}{W(u_{0,0}, \ldots, u_{0,N-1})}.
\] (45)

Below we will often use the abbreviations \( W(x) \), \( W_n(x) \) for the Wronskians (when there is no ambiguity in the definition of the transformation functions \( u_{0,n} \) in their arguments) indicating explicitly only the dependence on the spatial coordinate.

Within the above framework, the \( N \) first discrete levels \( E_0, E_1, \ldots, E_{N-1} \) have been removed from the spectrum of \( h_0 \) by choosing the ground state functions \( u_{k,k} \) of the Hamiltonians \( h_k \) as intermediate transformation functions. For such a construction the transformed propagator may be calculated according to

**Theorem 3.** Let the \( N \) first eigenfunctions \( u_{0,n} \equiv u_n = \psi_n, n = 0, \ldots, N - 1 \) of \( h_0 \) be the SUSY transformation functions. Then the propagators \( K_N(x,y;t) \) and \( K_0(x,y;t) \) of the Schrödinger equations with Hamiltonians \( h_N \) and \( h_0 \) are intertwined as

\[
K_N(x,y;t) = (-1)^N L_{N,0,x} \sum_{n=0}^{N-1} (-1)^n \frac{W_n(y)}{W(y)} \int_a^y K_0(x,z;t)u_n(z)dz
\] (46)

\[
= (-1)^{N-1} L_{N,0,x} \sum_{n=0}^{N-1} (-1)^n \frac{W_n(y)}{W(y)} \int_y^b K_0(x,z;t)u_n(z)dz.
\] (47)

**Proof.** The proof of these relations can be given by induction. We start with (47). For \( K_1(x,y;t) \) the statement is proven in (21). Assuming that (47) holds for \( K_N(x,y;t) \) we verify its validity for \( K_{N+1}(x,y;t) \). The corresponding Hamiltonians \( h_{N+1} \) and \( h_N \) are intertwined by the linear transformation \( L_{N+1,N} \) so that (21) is applicable and \( K_{N+1}(x,y;t) \) can be represented as

\[
K_{N+1}(x,y;t) = \frac{1}{u_{N,N}(y)} L_{N+1,N,x} \int_y^b K_N(x,z;t)u_{N,N}dz.
\]
Finally to obtain via (40). Applying the general relation (43) to (41) gives

\[ (-1)^{N-1}K_{N+1}(x,y;t) = \frac{1}{u_{N,N}(y)}L_{N+1,0,x} \]

\[ \times \sum_{n=0}^{N-1} (-1)^n C_{N,n}^{-1} \int_y^b dz \int_z^b dq u_{N,n}(z)u_{N,N}(z)K_0(x,q; t)u_{0,n}(q). \]  

(48)

The integration region of the double integral is the upper triangle of the rectangle \( y < z, q < b \) in the \((z,q)\)-plane. We replace this double integral by the difference of two double integrals over the whole rectangle and the lower triangle, respectively,

\[ (-1)^{N-1}K_{N+1}(x,y;t) = \frac{1}{u_{N,N}(y)}L_{N+1,0,x} \sum_{n=0}^{N-1} (-1)^n C_{N,n}^{-1} \]

\[ \times \left[ \int_y^b dz K_0(x,z; t)u_{0,n}(z) \int_y^b dq u_{N,n}(q)u_{N,N}(q) \right. \]

\[ \left. - \int_y^b dz K_0(x,z; t)u_{0,n}(z) \int_z^b dq u_{N,n}(q)u_{N,N}(q) \right]. \]

(49)

Here, we reshape the two integrals of the type \( \int^b dx u_{N,n}(q)u_{N,N}(q) \) as follows. First we note that \( u_{N,n} \) and \( u_{N,N} \) are solutions of the same Schrödinger equation with Hamiltonian \( h_N \) and therefore

\[ \int_\xi^b dq u_{N,n}(q)u_{N,N}(q) = \frac{W[u_{N,N}(\xi), u_{N,n}(\xi)]}{E_n - E_N} - W_{b,n} \]

\[ = \frac{u_{N,N}L_{N+1,N}u_{N,n}}{E_n - E_N} - W_{b,n} \]

(50)

where \( W_{b,n} := W[u_{N,N}(b), u_{N,n}(b)]/(E_n - E_N) \) and where the second equality was obtained via (40). Applying the general relation (43) to \( L_{N+1,N}u_{N,n} = u_{N+1,n} \) leads finally to

\[ \int_\xi^b dq u_{N,n}(q)u_{N,N}(q) = -C_{N,n}u_{N,N} \frac{W_n(u_0, \ldots, u_N)}{W(u_0, \ldots, u_N)} - W_{b,n} \]

\[ =: -C_{N,n}u_{N,N}(\xi) \frac{W(\xi)}{W(\xi)} - W_{b,n}. \]

(51)

With (51) as substitution rule the propagator (49) takes the form

\[ (-1)^{N-1}K_{N+1}(x,y;t) = -L_{N+1,0,x} \sum_{n=0}^{N-1} (-1)^n \frac{W_n(y)}{W(y)} \int_y^b dz K_0(x,z; t)u_{0,n}(z) \]

\[ + \frac{1}{u_{N,N}(y)}L_{N+1,0,x} \int_y^b dz K_0(x,z; t) \frac{u_{N,N}(z)}{W(z)} \sum_{n=0}^{N-1} (-1)^n u_{0,n}(z)W_n(z). \]

(52)

(The terms containing \( W_{b,n} \) exactly cancelled.) The sum

\[ S_N := \sum_{n=0}^{N-1} (-1)^n u_{0,n}W_n(u_0, \ldots, u_N) \]

(53)
in the second term can be calculated explicitly. Comparison with the evident determinant identity

\[
0 = \begin{vmatrix}
  u_{0,0} & \ldots & u_{0,N-1} & u_{0,N} \\
  u_{0,0} & \ldots & u_{0,N-1} & u_{0,N} \\
  \vdots & \ddots & \ddots & \vdots \\
  u_{0,0} & \ldots & u_{0,N-1} & u_{0,N}
\end{vmatrix}
= \begin{vmatrix}
  u_{0,0} & \ldots & u_{0,N-1} & 0 \\
  u_{0,0} & \ldots & u_{0,N-1} & u_{0,N} \\
  \vdots & \ddots & \ddots & \vdots \\
  u_{0,0} & \ldots & u_{0,N-1} & u_{0,N}
\end{vmatrix} + \begin{vmatrix}
  0 & \ldots & 0 & u_{0,N} \\
  u_{0,0} & \ldots & u_{0,N-1} & u_{0,N} \\
  \vdots & \ddots & \ddots & \vdots \\
  u_{0,0} & \ldots & u_{0,N-1} & u_{0,N}
\end{vmatrix}
\]

(54)

shows that (53) coincides with the decomposition of the first determinant in the second line of (54) over the elements of its first row. Hence, it holds

\[ S_N = (-1)^N u_{0,N} W(u_{0,0}, \ldots, u_{0,N-1}) . \]

Representing the ground state eigenfunctions \( u_{N,N} \) in (52) via (45) in terms of Wronskian fractions we find that

\[ \frac{u_{N,N}(z)}{W(z)} \sum_{n=0}^{N-1} (-1)^n u_{0,n}(z) W_n(z) = (-1)^N u_{0,N}(z) \]

and, hence, that the second term in (52) is nothing but the absent \( n = N \) summand of the sum in the first term. As a result, we arrive at

\[ K_{N+1}(x, y; t) = (-1)^N L_{N+1,0,x} \sum_{n=0}^{N} (-1)^n \frac{W_n(u_0, \ldots, u_N)}{W(u_0, \ldots, u_N)} \int_y^b K_0(x, z; t) u_{0,n}(z) dz \]

what completes the proof of (47). The representation (43) follows from (47) and the relations

\[ \int_a^b K_0(x, z; t) u_n(z) dz = u_n(x) \exp(-iE_n t) \quad L_{N,0,x} u_n(x) = 0 . \]

\[ \square \]

We note that in formulas (46) and (47) only one-dimensional integrals are present. In this way, they may turn out more convenient for concrete calculations than similar equations derived in [7].

Furthermore, we note the following. Theorem [3] is proven for the case when the \( N \) lowest discrete levels are removed from the spectrum of \( h_0 \) starting from the ground state level. This scenario corresponds to reducible supersymmetry. In order to see which of the conditions on the transformation functions \( u_{0,n} \) used for the construction of the propagator representations (46) and (47) are indeed necessary conditions one may simply insert \( K_N(x, y; t) \) directly into Schrödinger equation (13). It turns out that neither the condition of level deletion starting from the ground state nor a deletion of a level block without surviving levels inside is used. This means that equations (46) and (47) hold for any choice of transformation functions provided their Wronskian does not vanish inside the interval \((a, b)\), i.e. it holds for reducible as well as for irreducible SUSY transformation chains. A necessary but in general not sufficient condition for the nodelessness of the Wronskian is inequality (12) (for further details see [20]).
4.3. Strictly isospectral transformations

Strictly isospectral transformations can be generated with the help of unphysical solutions of the Schrödinger equation as transformation functions. In this section, we extend theorem 3 to models defined over the whole real line \((a, b) = (-\infty, \infty)\) by assuming transformation functions which vanish at one of the infinities \(x \to -\infty\) or \(x \to \infty\) and violate the Dirichlet BCs at the opposite infinities \((x \to \infty\) or \(x \to -\infty)\).

In accordance with \((40)\) and \((47)\) we formulate the corresponding relaxed version of theorem 3 as

**Theorem 4.** Let the transformation functions \(u_n(x)\) vanish at only one of the infinities \(x \to -\infty\) or \(x \to \infty\) of the real axis \(\mathbb{R}\). Then the propagators \(K_N(x, y; t)\) and \(K_0(x, y; t)\) of the Schrödinger equations with \(h_N\) and \(h_0\) as Hamiltonians are related as follows:

For \(u_n(x \to -\infty) \to 0:\)

\[
K_N(x, y; t) = (-1)^N L_x \sum_{n=0}^{N-1} (-1)^n \frac{W_n(y)}{W(y)} \int_{-\infty}^{y} K_0(x, z; t) u_n(z) dz
\]  

(55)

For \(u_n(x \to \infty) \to 0:\)

\[
K_N(x, y; t) = (-1)^{N-1} L_x \sum_{n=0}^{N-1} (-1)^n \frac{W_n(y)}{W(y)} \int_{y}^{\infty} K_0(x, z; t) u_n(z) dz
\]  

(56)

For \(u_k(x \to -\infty) \to 0\) \(k = 0, \ldots, M\) and \(u_m(x \to \infty) \to 0\) \(m = M + 1, \ldots, N - 1:\)

\[
K_N(x, y; t) = (-1)^N L_x \sum_{k=0}^{M} (-1)^n \frac{W_k(y)}{W(y)} \int_{-\infty}^{y} K_0(x, z; t) u_k(z) dz
\]  

\[
+ (-1)^{N-1} L_x \sum_{m=M+1}^{N-1} (-1)^m \frac{W_m(y)}{W(y)} \int_{y}^{\infty} K_0(x, z; t) u_m(z) dz.
\]  

(57)

**Proof.** We have to verify that the initial condition \(K_0(x, y; 0) = \delta(x - y)\) and the Schrödinger equations \((i\partial_t - h_0)x_k) K_0(x, y; t) = 0\) and \((i\partial_t - h_0)K_0(x, y; t) = 0\) fulfilled by the original propagator \(K_0(x, y; t)\) map into corresponding relations for the final propagator \(K_N(x, y; t)\), i.e. that \(K_N(x, y; 0) = \delta(x - y), (i\partial_t - h_N)K_N(x, y; t) = 0\) and \((i\partial_t - h_N)K_N(x, y; t) = 0\) are satisfied. We demonstrate the explicit proof for the setup with \(u_k(x \to -\infty) \to 0\) omitting the technically identical considerations for the other cases.

We start by noticing that the intertwiner \(L_x\) maps solutions of the Schrödinger equation for \(h_0\) into solutions of the Schrödinger equation for \(h_N\) and, hence, \((i\partial_t - h_N)K_N(x, y; t) = 0\) is automatically satisfied.

Next, we consider the initial condition \(K_N(x, y; 0) = \delta(x - y)\) which should be fulfilled by the r.h.s. of \((57)\). With \(K_0(x, y; 0) = \delta(x - y)\) and \(\int_{-\infty}^{y} \delta(x - z) u_n(z) dz = \theta(y - x) u_n(x)\) we have from \((57)\)

\[
K_N(x, y; 0) = (-1)^N \sum_{n=0}^{N-1} (-1)^n \frac{W_n(y)}{W(y)} L_{N,0,x}[\theta(y - x) u_n(x)].
\]  

(58)
Exact propagators for SUSY partners

In the Crum-Krein formula (see (7))

\[ L_{N,0,x}[^{\theta}(x-y)u_n(x)] = W[u_0,\ldots,u_{N-1},^{\theta}(x-y)u_n(x)] \]

(59)

we represent the derivatives \( \partial_x^m[^{\theta}(y-x)u_n(x)] \), \( m=0,\ldots,N \) as

\[ \partial_x^m[^{\theta}(y-x)u_n(x)] = \sum_{k=0}^{m-1} C_k^m \theta_x^{(m-k)}(y-x)u_n^{(k)}(x) + \theta(y-x)u_n^{(m)}(x), \]

(60)

\[ \theta_x^{(m-k)}(y-x) := \partial_x^{m-k}\theta(y-x). \]

Taking into account that

\[ | u_0(x) \ldots u_{N-1}(x) \theta(y-x)u_n(x) | \]
\[ | u'_0(x) \ldots u'_{N-1}(x) \theta(y-x)u'_n(x) | \]
\[ \ldots \ldots \ldots \]
\[ | u^{(N)}_0(x) \ldots u^{(N)}_{N-1}(x) \theta(y-x)u^{(N)}_n(x) | \]

\( = 0 \)

and making use of the linearity properties of determinants we reshape (59) as

\[ L_{N,0,x}[^{\theta}(x-y)u_n(x)] = \frac{1}{W(x)} \begin{vmatrix} u_0(x) & \ldots & u_{N-1}(x) & \theta(y-x)u_n(x) \\ u'_0(x) & \ldots & u'_{N-1}(x) & -\delta(x-y)u_n(x) \\ \ldots & \ldots & \ldots & \ldots \\ u^{(N)}_0(x) & \ldots & u^{(N)}_{N-1}(x) & \sum_{k=0}^{N-1} C_k^N \theta_x^{(N-k)}(y-x)u_n^{(k)}(x) \end{vmatrix}. \]

(61)

Expanding this determinant with regard to the elements of the last column we find

\[ L_{N,0,x}[^{\theta}(x-y)u_n(x)] = \frac{(-1)^N}{W(x)} \sum_{m=1}^{N} (-1)^m W_{N,m}(x) \sum_{k=0}^{m-1} C_k^m \theta_x^{(m-k)}(y-x)u_n^{(k)}(x) \]

(62)

where \( W_{N,m}(x) \) are corresponding minors. For the verification of the relation \( K_N(x,y;0) = \delta(x-y) \) we use its representation

\[ \int_{-\infty}^{\infty} K_N(x,y;0)f(x)dx = f(y) \]

(63)

where \( f(x) \) is a sufficiently smooth test function with compact support. With (62) and (63) the l.h.s. of (63) reads

\[ \sum_{n=0}^{N-1} \sum_{m=1}^{N} \sum_{k=0}^{m-1} (-1)^{n+m} C_k^m W_{n}(y) \int_{-\infty}^{\infty} \theta_x^{(m-k)}(y-x) \frac{W_{N,m}(x)f(x)u_n^{(k)}(x)}{W(x)} dx. \]

(64)

As next step, we use \( \theta_x^{(m-k)}(y-x) = -\delta^{m-k-1}(y-x) \) and multiple integration by parts to remove the derivatives from the \( \theta \)-functions:

\[ \text{l.h.s. of (63)} = \sum_{n=0}^{N-1} \sum_{m=1}^{N} \sum_{k=0}^{m-1} (-1)^{n-k} C_k^m \frac{W_{n}(y)}{W(y)} \theta^{(m-k)}_y \left[ \frac{W_{N,m}(y)f(y)u_n^{(k)}(y)}{W(y)} \right]. \]

(65)

The relation

\[ \frac{1}{W} \sum_{n=0}^{N-1} (-1)^n W_n u_n^{(j)} = (-1)^N \delta_{j,N-1}, \quad j = 0, \ldots, N - 1 \]

(66)

\(^{10)}\) For the theory of distributions (generalized functions) see, e.g., [24] (in particular vol.1 p. 26).
reduces this multiple sum to

\[
\text{l.h.s. of (53)} = (-1)^N \sum_{k=0}^{N-1} (-1)^k C_k^N
\]

(67)

and because of \(W_{NN}(y) = W(y)\) and \(\sum_{k=0}^{N-1} (-1)^k C_k^N = (-1)^N\) (cf. 4.2.1.3 in [28]) the condition (53) is satisfied.

It remains to prove that the Schrödinger equation \((i\partial_t - h_{Ny})K_N(x,y,t) = 0\) is fulfilled too. By explicit substitution of equation (55) we have

\[
(i\partial_t - h_{Ny})K_N(x,y,t)
= (-1)^N L_x \sum_{n=0}^{N-1} (-1)^n \frac{W_n(y)}{W(y)} \left[ \int_{-\infty}^{y} i\partial_t K_0(x,z;t)u_n(z)dz + L_x \left( \frac{W_n(y)}{W(y)} \right) u_n(y) + W_n(y) \left( \frac{W_n(y)}{W(y)} \right) u_n(y) \right] K_0(x,y,t).
\]

(68)

First, we note that due to relation (66) and its derivative the last sum vanishes. Taking further into account that \(W_n(y)/W(y)\) is a solution of the Schrödinger equation for \(h_N\) at energy \(E_n\) (cf. (10)) and replacing \(i\partial_t K_0(x,z;t) \rightarrow h_{0z} K_0(x,z;t)\) one reduces equation (66) to

\[
(i\partial_t - h_{Ny})K_N(x,y,t)
= (-1)^N L_x \sum_{n=0}^{N-1} (-1)^n \frac{W_n(y)}{W(y)} \left[ (h_{0z} - E_n)K_0(x,z;t) \right] u_n(z)dz.
\]

(69)

Integrating by parts and making use of \((h_{0z} - E_n)u_n(z) = 0\), the asymptotical behavior \(u(z \rightarrow -\infty) \rightarrow 0\), \(u'(z \rightarrow -\infty) \rightarrow 0\) and relation (66) one finds that the r.h.s. in (69) vanishes and, hence, the Schrödinger equation \((i\partial_t - h_{Ny})K_N(x,y,t) = 0\) is fulfilled.

4.4. General polynomial supersymmetry

The three different types of transformations considered above may be combined in various ways to produce a supersymmetry of more general type. In general, from the spectrum of the original Hamiltonian \(h_0\) \(q\) levels may be added and \(p\) additional levels may be added, \(p + q \leq N\) producing in this way the spectral set of \(h_N\). The inequality would correspond to SUSY transformation chains between \(h_0\) and \(h_N\) which contain isospectral transformations. For further convenience we split the spectra of \(h_0\) and \(h_N\) according to their transformation related contents as

\[
\text{spec}(h_0) = \{\epsilon_i, \beta_j, E_k\}, \quad i = 1, \ldots, q; \quad j = 1, \ldots, N - (p + q + r)
\]

\[
\text{spec}(h_N) = \{\lambda_l, \beta_j, E_k\}, \quad l = 1, \ldots, p; \quad j = 1, \ldots, N - (p + q + r)
\]

(70)

where the discrete levels \(E_k\) and the continuous spectrum \(\text{spec}_c(h_0) = \text{spec}_c(h_N)\) are not affected by the SYSY transformations. The set of transformation constants \(\{\alpha_n\}_{n=1}^{N-1} = \{\epsilon_i, \lambda_l, \beta_j, \gamma_k\}\) corresponds to \(p\) new discrete levels \(\lambda_n \in \text{spec}(h_N)\) not present in \(\text{spec}(h_0)\), \(q\) levels \(\epsilon_i \in \text{spec}(h_0)\) not present in \(\text{spec}(h_N)\), \(N - (p + q + r)\)
levels $\beta_1$ present in both spectra and $r$ constants $\gamma_k$ not coinciding with any energy level of both Hamiltonians, $\gamma_k \not\in \text{spec}(h_0) \cup \text{spec}(h_N)$. Transformations induced at constants $\alpha_n = \beta_n, \gamma_n$ are strictly isospectral.

Summarizing the previous results the following expression for the propagator $K_N(x,y,t)$ can be given

\[ K_N(x,y,t) = \sum_{n=0}^{N-1} \left( \prod_{j=0,j \neq n}^{N-1} \frac{1}{\alpha_n - \alpha_j} \right) \int_{-\infty}^{\infty} K_0(x,z,t) G_0(z,y,\alpha_n) \, dz \]

\[ + \sum_{\lambda_n} \phi_{\lambda_n}(x) \phi_{-\lambda_n}(y) e^{-i\lambda_n t} + \sum_{\beta_n} \phi_{\beta_n}(x) \phi_{\beta_n}(y) e^{-i\beta_n t} \]

where $\alpha_n = \varepsilon_n, \beta_n = \lim_{E \to \alpha_n} \left[ G_0(z,y,E) - \frac{\psi_n(x)\psi_n(y)}{\alpha_n - E} \right]$ and $G_0(z,y,\alpha_n) = G_0(z,y,\alpha_n)$ otherwise.

5. Applications

5.1. Particle in a box

As first application we consider a free particle in a box, i.e. the Schrödinger equation with $V_0(x) \equiv 0$ and Dirichlet BCs at the ends of the finite interval $(0,1)$. The eigenfunctions of this problem are the well known $\psi_{n-1}(x) = \sqrt{2} \sin(n\pi x)$, $n = 1, 2, \ldots$ with energies $E_{n-1} = n^2\pi^2$. The corresponding propagator reads

\[ K_{\text{box0}}(x,y,t) = \frac{1}{2} \left[ \vartheta_3^- (x,y;t) - \vartheta_3^+ (x,y;t) \right] \]

with

\[ \vartheta_3^- (x,y;t) := \vartheta_3 \left( \frac{x - y}{2} - \frac{\pi t}{2} \right), \quad \vartheta_3^+ (x,y;t) := \vartheta_3 \left( \frac{x + y}{2} - \frac{\pi t}{2} \right) \]

and $\vartheta_3(q|r)$ denoting the third theta function.

As SUSY partner problem we choose a model which we derive by removing the ground state level $E_0$ by a linear (one-step) SUSY-mapping with $u = \psi_0 = \sin \pi x$ as transformation function. This leads to the Schrödinger equation with potential $V_1(x) = 2\pi^2 / \sin^2(\pi x)$, i.e. a singular Sturm-Liouville problem. The propagator of this problem can be represented via $K_{\text{box1}}(x,y,t)$ as

\[ K_{\text{box1}}(x,y,t) = -\frac{1}{2 \sin \pi y} \int_0^y \left[ \vartheta_3^- (x,z;t) - \vartheta_3^+ (x,z;t) \right] \sin(\pi z) \, dz \]

or after explicit substitution of $L_x = -\pi \cot(\pi x) + \partial_x$ as

\[ K_{\text{box1}}(x,y,t) = \frac{\pi \cot(\pi y)}{2 \sin(\pi y)} \int_0^y \left[ \vartheta_3^- (x,z;t) - \vartheta_3^+ (x,z;t) \right] \sin(\pi z) \, dz \]

\[ - \frac{\pi}{2 \sin(\pi y)} \int_0^y \left[ \vartheta_3^- (x,z;t) + \vartheta_3^+ (x,z;t) \right] \cos(\pi z) \, dz + \frac{1}{2} \left[ \vartheta_3^- (x,y;t) + \vartheta_3^+ (x,y;t) \right]. \]

Here after using the property $\partial_x \theta_3^\pm (x,z,t) = \pm \partial_x \theta_3^\pm (x,z,t)$ we integrated in $K_{\text{box1}}(x,y,t)$ by parts.

\[ \text{[11]} \text{There exist other types of transformations leading to regular transformed Sturm-Liouville problems. But the solutions of the resulting Schrödinger equations will violate the Dirichlet BCs so that a special analysis is needed.} \]
5.2. Harmonic oscillator

Here we consider the Hamiltonian

\[ h_0 = -\partial_{xx}^2 + \frac{x^2}{4}. \]

Using a two-fold transformation with transformation functions

\[ u_2(x) = (x^2 - 1)e^{-x^2/4} \quad u_3(x) = x(x^2 - 3)e^{-x^2/4} \]

corresponding to the second and third excited state eigenfunctions of \( h_0 \) we obtain a perturbed Harmonic oscillator potential \[ V^{(2,3)}(x) = \frac{8x^2}{x^4 + 3} - \frac{96x^2}{(x^4 + 3)^2} + \frac{x^2}{4} + 2 \]

(74)

which for large \(|x|\) behaves like the original harmonic oscillator potential, but for small \(|x|\) shows two shallow minima. For completeness, we note that the transformation functions \( u_2(x) \) and \( u_3(x) \) have nodes, whereas their Wronskian \[ W(u_2, u_3) = (x^4 + 3)e^{-x^2/2} \]

is nodeless so that the corresponding second-order SUSY-transformation itself is well defined, but irreducible.

The propagator for the Schrödinger equation with Hamiltonian \( h^{(2,3)} = -\partial_x^2 + V^{(2,3)}(x) \) can be constructed from the well known propagator

\[ K_{osc}(x, y, t) = \frac{1}{\sqrt{4\pi i \sin t}} e^{i(x^2 + y^2 + 2xy)/4\sin t}. \]

for the \( h_0 \)-Schrödinger equation (see e.g. [27]) via relation (56). The occurring integrals \( \int_y^{\infty} K_{osc}(x, z, t)u_n(z)\,dz \) can be represented as derivatives with respect to the auxiliary current \( J \) of the generating function

\[ S(J, x, y, t) = \frac{1}{\sqrt{4\pi i \sin t}} \int_y^{\infty} \exp \left[ \frac{i[(x^2 + z^2)\cos t - 2xz]}{4\sin t} - \frac{z^2}{4} + Jz \right] \,dz \]

\[ = \frac{1}{2} \exp \left( \frac{-2it - x^2}{4} + iJ^2 \sin t + Jx \exp(-it) \right) \]

\[ \times \left( 1 + \text{erf} \left( \frac{-\sqrt{\exp(-\frac{4t}{J})}}{2\sqrt{\sin t}} (2J\sin t + i(y\exp(it) - x)) \right) \right). \]

As a result, we obtain

\[ K^{(2,3)}(x, y, t) = e^{y^2/2L_x} \left( \frac{y(y^2 - 3)}{y^4 + 3} \left[ \frac{\partial^2 S(J)}{\partial J^2} - S(J) \right] - \frac{y^2 - 1}{y^4 + 3} \left[ \frac{\partial^3 S(J)}{\partial J^3} - 3 \frac{\partial S(J)}{\partial J} \right] \right)_{J=0} \]

in terms of obvious abbreviations.

The technique can be straightforwardly generalized to second-order SUSY-transformations built on any eigenfunction pair

\[ u_k(x) = p_k(x)e^{-x^2/4} \quad u_{k+1}(x) = p_{k+1}(x)e^{-x^2/4} \]

of the Hamiltonian \( h_0 \). The corresponding generalized potentials \( V^{(k,k+1)}(x) \) (see [4]) read

\[ V^{(k,k+1)}(x) = -2Q''_k(x)Q_k(x) + 2 \left( \frac{Q'_k(x)}{Q_k(x)} \right)^2 + \frac{x^2}{4} + 4 \]

(75)
where
\[ Q_k(x) := p_{k+1}^2(x) - p_k(x)p_{k+2}(x) \quad \text{and} \quad W(u_k, u_{k+1}) = -Q_k(x)\exp\left(-x^2/2\right) \]
are built from the re-scaled Hermite polynomials \( p_k(x) = 2^{-k/2}H_k(x/\sqrt{2}) \).

With the help of (46), the propagator is obtained as
\[
K^{(k,k+1)}(x,y,t) = e^{x^2/2}L_x \left( \frac{p_{k+1}(y)}{Q_k(y)} \left[ p_k(\partial_J) S(J) \right] - \frac{p_k(y)}{Q_k(y)} \left[ p_{k+1}(\partial_J) S(J) \right] \right) J = 0 \quad (76)
\]
with \( p_k(\partial_J) \) denoting the \( k \)-th-order differential operator obtained from \( p_k(x) \) by replacing \( x^n \rightarrow \frac{\partial^n}{\partial J^n} \).

Finally we note that the potentials (75) behave asymptotically like \( x^2/4 \) for \(|x| \rightarrow \infty\) and have \( k \) shallow minima at their bottom.

5.3. Transparent potentials

Here we apply our propagator calculation method to transparent potentials which are SUSY partners of the zero potential in models defined over the whole real axis. We note that the propagator for a one-level transparent potential was previously calculated by Jauslin [7] for the Fokker-Planck equation. The propagator for a two-level potential can be found in [9] where the general form of the propagator for an \( N \)-level potential has been given as a conjecture. Here we will prove this conjecture.

We construct the \( N \)-level transparent potential from the zero potential with the help of the following \( N \) solutions of the Schrödinger equation with \( V_0(x) \equiv 0 \) (see e.g. [3])
\[
u_{2j-1}(x) = \cosh(a_{2j-1}x + b_{2j-1}) \]
\[
u_{2j}(x) = \sinh(a_{2j}x + b_{2j}) \quad j = 1, 2, \ldots, [(N + 1)/2]
\]
as transformation functions. Here, \( a_i, b_i \in \mathbb{R} \), \( a_i > a_{i+1} > 0 \) is assumed and \([(N + 1)/2]\) denotes the integer part of \((N + 1)/2\).

The factorization constants \( \alpha_j = -a_j^2 \) define the positions of the discrete levels (point spectrum) \( E_j = \alpha_j < 0 \) of \( h_N = -\partial_x^2 + V_N(x) \), whereas the continuous part of the spectrum of \( h_N \) fills the whole real axis. The eigenfunctions of the discrete levels normalized to unity have the form [2]
\[
\varphi_n(x) = \left[ \frac{a_n}{2} \prod_{j=1, j\neq n}^N |a_j^2 - a_n^2| \right]^{1/2} \frac{W(u_1, u_2, \ldots, u_{n-1}, u_{n+1}, \ldots, u_N)}{W(u_1, u_2, \ldots, u_N)} \quad (78)
\]
The propagator \( K_0 \) and the Green function \( G_0 \) for the free particle are well-known [1]
\[
K_0(x,y;t) = \frac{1}{\sqrt{4\pi it}} e^{i(x-y)^2/4t} \]
\[
G_0(x,y,E) = \frac{i}{2\kappa} e^{i\kappa|x-y|} \quad \text{Im} \kappa > 0 \quad E = \kappa^2 \quad (79)
\]
so that according to (39) the propagator of the transformed system can be calculated as
\[
K_N(x,y,t) = \left( \frac{L_x L_y}{\sqrt{4\pi it}} \sum_{n=1}^N \left( \prod_{j=1, j\neq n}^N \frac{1 - \alpha_n - \alpha_j}{\alpha_n - \alpha_j} \right) \int_{-\infty}^\infty \exp \left( \frac{i(x-z)^2}{4t} - \alpha_n |z - y| \right) \frac{dz}{2\alpha_n} \right)
\]
\[
+ \sum_{n=1}^N \varphi_n(x) \varphi_n(y) e^{-i\alpha_n t} =: K_cN(x,y,t) + K_dN(x,y,t) \quad (80)
\]
In the last line we separated contributions from the continuous spectrum, \( K_cN(x,y,t) \), from contributions from the discrete spectrum, \( K_dN(x,y,t) \).

The integral in \( K_cN(x,y,t) \) can easily be calculated since the primitive of the integrand is well known (see e.g. integral 1.3.3.17 of Ref \[28\]). Using the well studied convergency conditions of the error-function \( \text{erfc} \) from \[29\] we find

\[
I(a,x,y,t) := \frac{1}{\sqrt{4\pi it}} \int_{-\infty}^{\infty} \exp \left( \frac{i(x - z)^2}{4t} - a|z - y| \right) \frac{dz}{2a}
\]

\[
= \frac{e^{a^2t}}{4a} \left[ e^{a(x-y)} \text{erfc} \left( a\sqrt{it} + \frac{x-y}{2\sqrt{it}} \right) + e^{a(y-x)} \text{erfc} \left( a\sqrt{it} - \frac{x-y}{2\sqrt{it}} \right) \right]
\]  

\[a > 0 \quad t > 0\]

and with it

\[
K_cN(x,y; t) = L_z L_y \sum_{n=1}^{N} \left( \prod_{m=1, m \neq n}^{N} \frac{1}{\alpha_n - \alpha_m} \right) I(a_n, x,y,t). \tag{82}
\]

Introducing the notation

\[
\text{erf}_\pm(a) := \text{erf} \left( a\sqrt{it} \mp \frac{x-y}{2\sqrt{it}} \right)
\]

and abbreviating the Wronskian of the \( x \)-dependent transformation functions \( u_1, \ldots, u_N \) as \( W(x) \) we formulate the final expression for the propagator as

**Theorem 5.** The propagator for an \( N \)-level transparent potential has the form

\[
K_N(x,y; t) = \frac{1}{\sqrt{4\pi it}} e^{\frac{i(x-y)^2}{4t}} + \sum_{n=1}^{N} \left( \prod_{j=1, j \neq n}^{N} \frac{1}{\alpha_n - \alpha_j} \right) \frac{W_n(x)W_n(y)}{W(x)W(y)} e^{i\alpha_n^2 t} \left[ \text{erf}_+(a_n) + \text{erf}_-(a_n) \right]. \tag{83}
\]

For the proof of this theorem we need the additional

**Lemma 3.** Let \( \{\alpha_i\}_{i=1}^{N} \) be a set of \( N \) non-coinciding complex numbers \( a_i \neq a_j \neq i \in \mathbb{C} \) and \( n \in \mathbb{Z}^+ \). Then the following identity holds:

\[
\sum_{i=1}^{N} \alpha_i^n \left( \prod_{j=1, j \neq i}^{N} \frac{1}{\alpha_i - \alpha_j} \right) = \delta_{n,N-1}. \tag{84}
\]

**Proof.** Consider the auxiliary function

\[
f(z) = \frac{z^n}{(z - \alpha_1)(z - \alpha_2)\ldots(z - \alpha_N)}
\]

which is analytic in any finite part of the complex \( z \)-plane except for \( N \) simple poles \( \alpha_1, \ldots, \alpha_N \). From the residue theorem follows

\[
\sum_{i=1}^{N} \text{res} f(\alpha_i) = \sum_{i=1}^{N} \alpha_i^n \left( \prod_{j=1, j \neq i}^{N} \frac{1}{\alpha_i - \alpha_j} \right) = -\text{res} f(\infty)
\]

what with the residue at infinity yields \[84\].

\[12\] We use the standard notation \( \mathbb{Z}^+ = \{0, 1, 2, \ldots\} \) for the natural numbers with zero included.
As the next step we prove Theorem \[5\].

**Proof.** Without loss of generality we may set \(b_j = 0\). We start with the propagator component \(K_{cN}(x, y, t)\) in \([52]\) related to the continuous spectrum. First we note that the function \(J\) in \([52]\) depends only via the difference \(x - y\) on the spatial coordinates so that the action of \(\partial_y\) in \(L_y\) can be replaced by \(\partial^n \rightarrow (-1)^n \partial^n\). Hence, the composition of the two \(N\)-th order transformation operators \(L_x L_y\) acts as an effective 2\(N\)th-order differential operator in \(x\)

\[
L_x L_y = R_0 + R_1 \partial_x + \ldots + R_{2N} \partial_x^{2N}
\]

with coefficient functions \(R_n(x, y)\). Accordingly, \([52]\) takes the form

\[
K_{cN}(x, y; t) = \sum_{n=1}^{N} \left( \prod_{m=1, m \neq n}^{N} \frac{1}{\alpha_n - \alpha_m} \right) [R_0 + R_1 \partial_x + \ldots + R_{2N} \partial_x^{2N}] J_n
\]

where \(J_n = I(a_n, x, y, t)\). From the explicit structure of the first derivatives of \(J_n\)

\[
\frac{\partial J_n}{\partial x} = \frac{1}{4} \left[ e^{-a_n(x-y)} \text{erfc} + (a_n) + e^{a_n(x-y)} \text{erfc} - (a_n) \right] e^{ia_n^2 t}
\]

\[
\frac{\partial^2 J_n}{\partial x^2} = \frac{1}{4} \frac{e^{i(x-y)^2}}{\sqrt{4\pi t}} + a_n^2 I(a_n)
\]

\[
\frac{\partial^3 J_n}{\partial x^3} = \frac{1}{2} \frac{1}{2t \sqrt{4\pi t}} \frac{e^{i(x-y)^2}}{\sqrt{4\pi t}}
\]

we find (by induction) the general expression of an even-order derivative

\[
\frac{\partial^{2m} I}{\partial x^{2m}} = \sum_{k=0}^{m-1} a_n^{2k} A_{km}(x, y, t) e^{i(x-y)^2 / 4t} + \frac{a_n^{m-1}}{4} e^{i a_n^2 t} \left[ e^{-a_n(x-y)} \text{erfc} + (a_n) + e^{a_n(x-y)} \text{erfc} - (a_n) \right]
\]

and of an odd-order derivative

\[
\frac{\partial^{2m-1} I}{\partial x^{2m-1}} = \sum_{k=0}^{m-2} a_n^{2k} A_{km}(x, y, t) e^{i(x-y)^2 / 4t} - \frac{a_n^{m-1}}{4} e^{i a_n^2 t} \left[ e^{-a_n(x-y)} \text{erfc} + (a_n) - e^{a_n(x-y)} \text{erfc} - (a_n) \right]
\]

It holds

\[
A_{km}(x, y, t) \equiv 0 \iff \left\{ \begin{array}{l} m = 2l \quad \cap \quad k > l - 1 \\ m = 2l + 1 \quad \cap \quad k > l - 1 \end{array} \right.
\]

Subsequently we use the abbreviation

\[
I_m(a_n) = \frac{1}{4 a_n} e^{i a_n^2 t} \left[ (-1)^m e^{-a_n(x-y)} \text{erfc} + (a_n) + e^{a_n(x-y)} \text{erfc} - (a_n) \right]
\]
Thus, the above formula reduces to

\[
\frac{\partial^{2N} J_n}{\partial x^{2N}} = \ldots - a_n^{2(N-1)} \frac{1}{\sqrt{4\pi t}} e^{\frac{ix-y^2}{4t}} + a_n^{2N} J_{2N}.
\] (91)

The complete propagator component \(K_{cN}(x, y; t)\) in (80) can now be rewritten as

\[
K_{cN}(x, y; t) = \sum_{n=1}^{N} \left( \prod_{m=1, m \neq n}^{N} \frac{1}{\alpha_n - \alpha_m} \right) R_0 I_0(a_n)
\]

\[+ \sum_{n=1}^{N} \left( \prod_{m=1, m \neq n}^{N} \frac{1}{\alpha_n - \alpha_m} \right) a_n R_1 I_1(a_n)
\]

\[+ \sum_{n=1}^{N} \left( \prod_{m=1, m \neq n}^{N} \frac{1}{\alpha_n - \alpha_m} \right) R_2 \left[ - \frac{1}{\sqrt{4\pi t}} e^{\frac{i(x-y)^2}{4t}} + a_n^{2N} I_{2N}(a_n) \right] + \ldots
\]

\[+ \sum_{n=1}^{N} \left( \prod_{m=1, m \neq n}^{N} \frac{1}{\alpha_n - \alpha_m} \right) R_{2N} \left[ \sum_{k=0}^{N-1} a_n^{2k} A_{k,2N}(x, y, t) e^{\frac{i(x-y)^2}{4t}} + a_n^{2N} I_{2N}(a_n) \right].
\]

Comparison with Lemma 3 shows that due to \(a_n^{2k} = (-\alpha_n)^k\) only a single term containing \(\exp(i(x-y)^2/4t)\) does not vanish. It is the \(k = N - 1\) term in the very last sum which with \(R_{2N} = (-1)^N\) and \(A_{N-1,2N}(x, y, t) = -(4\pi t)^{N-1/2}\) yields exactly the propagator (79) of the free particle. All other terms containing \(\exp(i(x-y)^2/4t)\), after interchanging the sums \(\sum_{n=1}^{N} \ldots\) and \(\sum_{k=0}^{N-1} \ldots\), cancel out due to Lemma 3.

Thus, the above formula reduces to

\[
K_{cN}(x, y; t) = \frac{1}{\sqrt{4\pi t}} e^{\frac{i(x-y)^2}{4t}} + \sum_{n=1}^{N} \left( \prod_{m=1, m \neq n}^{N} \frac{1}{\alpha_n - \alpha_m} \right) R_0 I_0(a_n)
\]

\[\times \left[ R_0 I_0(a_n) + R_1 a_n I_1(a_n) + R_2 a_n^2 I_2(a_n) + R_3 a_n^3 I_3(a_n) + \ldots + R_{2N} a_n^{2N} I_{2N}(a_n) \right].
\] (92)

Expressing \(I_n(a_n)\) via (90) in terms of \(\text{erfc}_+\) and \(\text{erfc}_-\) one finds contributions

\[
\frac{\text{erfc}_+(a_n)}{4a_n} e^{ia_2t} (R_0 - a_n R_1 + a_n^2 R_2 - a_n^3 R_3 + \ldots + a_n^{2N} R_{2N}) e^{-a_n(x-y)}
\]

\[
\frac{\text{erfc}_-(a_n)}{4a_n} e^{ia_2t} (R_0 + a_n R_1 + a_n^2 R_2 + a_n^3 R_3 + \ldots + a_n^{2N} R_{2N}) e^{a_n(x-y)}
\]

which can be represented as

\[
\frac{\text{erfc}_+(a_n)}{4a_n} e^{ia_2t} (R_0 + R_1 \partial_x + R_2 \partial_x^2 + R_3 \partial_x^3 + \ldots + R_{2N} \partial_x^{2N}) e^{-a_n(x-y)}
\]

\[
\frac{\text{erfc}_-(a_n)}{4a_n} e^{ia_2t} (R_0 + R_1 \partial_x + R_2 \partial_x^2 + R_3 \partial_x^3 + \ldots + R_{2N} \partial_x^{2N}) e^{a_n(x-y)}.
\]

Comparison with (85) shows that the sums yield simply \(L_x L_y \exp[\pm a_n(x - y)]\). Recalling furthermore that the transformation operators \(L_x\) and \(L_y\) are given by (77)
Exact propagators for SUSY partners

and that the transformation functions have the form \(^{13}\) we arrive after some algebra at

\[ L_x e^{\pm \alpha_n x} = (\mp 1)^n (-1)^{N+n-1} \alpha_n \prod_{j=1, j \neq n}^N (\alpha_j^2 - \alpha_n^2) \frac{W_n(x)}{W(x)} \]

(93)

and, hence, at

\[ L_x L_y e^{\pm \alpha_n (x-y)} = (-1)^n \alpha_n^2 \prod_{j=1, j \neq n}^N (\alpha_n^2 - \alpha_j^2)^2 \frac{W_n(x)W_n(y)}{W(x)W(y)}. \]

(94)

Substituting (94) into (92) we obtain

\[ K_{cN}(x, y; t) = \frac{1}{\sqrt{4\pi if}} e^{i\frac{(y-x)^2}{4f}} + \frac{1}{4} \sum_{n=1}^N e^{i\alpha_n^2 t} \alpha_n \left( \prod_{m=1, m \neq n}^N \frac{(-1)^n (\alpha_n^2 - \alpha_m^2)^2}{\alpha_n - \alpha_m} \right) \times \frac{W_n(x)W_n(y)}{W(x)W(y)} [\text{erfc}(a_n) + \text{erfc}(-a_n)]. \]

(95)

A further simplification can be achieved by recalling that \( \alpha_n = -\alpha_n^2 \) and that the parameters \( a_n \) are ordered as \( a_1 < a_2 < \ldots < a_N \). Setting \( (\alpha_n^2 - \alpha_m^2) = -\alpha_n^2 - \alpha_m^2 \) in the denominator for \( m = 1, \ldots, n - 1 \) gives an additional sign factor \((-1)^{n-1}\). The propagator sum \( K_N = K_{cN} + K_{dN} \) resulting from continuous and discrete spectral components reads then

\[ K_N(x, y; t) = \frac{1}{\sqrt{4\pi if}} e^{i\frac{(y-x)^2}{4f}} - \frac{1}{4} \sum_{n=1}^N e^{i\alpha_n^2 t} \alpha_n \left( \prod_{m=1, m \neq n}^N |\alpha_n^2 - \alpha_m^2| \right) \times \frac{W_n(x)W_n(y)}{W(x)W(y)} [\text{erfc}(a_n) + \text{erfc}(-a_n)] + \frac{1}{2} \sum_{n=1}^N e^{i\alpha_n^2 t} \alpha_n \left( \prod_{m=1, m \neq n}^N |\alpha_n^2 - \alpha_m^2| \right) \frac{W_n(x)W_n(y)}{W(x)W(y)}. \]

(96)

and via the relation \( \text{erfc}(z) = 1 - \text{erf}(z) \) it leads to the expression in the theorem. \( \square \)

6. Conclusion

A careful study of propagators for SUSY partner Hamiltonians is given. Assuming the partner Hamiltonians linked by polynomial supersymmetry of a general type we derived user friendly expressions interrelating the corresponding associated propagators. Since the propagators may be also defined in terms of continual integrals the results should be useful in exploring new classes of continual integrals. We applied our general technique to derive propagators for transparent potentials and for a family of SUSY partner potentials of the Harmonic Oscillator. Further applications can be expected in time-evolution scenarios for particles placed in corresponding potential

\(^{13}\) We note that equation (93) is compatible with (78). The function \( \exp(-\alpha_n x) \) is a solution of the initial Schrödinger equation related to one of the factorization constants and it is linearly independent from the corresponding factorization solution. Therefore \( L_x \exp(-\alpha_n x) \) up to a constant factor is one of the bound state functions of \( h_N \) given in (83).
fields, in stochastic processes described by Focker-Planck equations (see e.g. [7]), in statistical physics and possibly in dynamo processes of magnetohydrodynamics [30].

Appendix A.

Here we derive a representation of the unphysical auxiliary solutions \(u_{N,n}, n = 0, \ldots, N - 1\) of the \(h_N\)-Schrödinger equation in terms of Wronskian fractions. We start by recalling that the functions \(u_{N,n}\) are defined by acting with an \(N\)-th-order (polynomial) SUSY-transformation operator \(L_{N,0}\) on the unphysical solutions \(u_{0,n}\) of the Schrödinger equation with Hamiltonian \(h_0\) at energies \(E_n = \alpha_n\). The functions are linearly independent from their physical counterparts \(u_{0,n}\) and normalized as \(W(u_{0,n}, u_{0,n}) = 1\). The operator \(L_{N,0}\) itself is constructed from the \(u_{0,n}, n = 0, \ldots, N - 1\) as transformation functions.

Below we show by induction that the unphysical solutions \(u_{N,0}\) defined in (42) as

\[
u_{N,n} = L_{N,0} \tilde{u}_{0,n} = L_{N,0} u_{0,n} \int_{x_0}^{x} \frac{dy}{W_0(y)}
\]

have the following representation in terms of Wronskian fractions

\[
u_{N,n} = C_{N,n} \frac{W(u_{0,0}, \ldots, u_{0,N-1})}{W(u_{0,0}, \ldots, u_{0,N-1})}
\]

(A.1)

where

\[
C_{N,n} := (E_{N-1} - E_n)(E_{N-2} - E_n) \ldots (E_{n+1} - E_n) \quad n = 0, \ldots, N - 2
\]

(A.2)

For \(N = 1\) the first order transformation operator \(L_{1,0}\) is constructed with the help of \(u_{0,0}\). Therefore applying (9) with \(f = \tilde{u}_{0,0}\) yields

\[
u_{1,0} = L_{1,0} \tilde{u}_{0,0} = \frac{1}{u_{0,0}}
\]

which obviously agrees with the statement. Applying (9) with \(f = u_{0,1}\) we obtain

\[
u_{1,1} = L_{1,0} u_{0,1} = \frac{W(u_{0,0}, u_{0,1})}{u_{0,0} u_{0,1}}
\]

(A.3)

In order to prove the statement for \(N = 2\) we build the linear SUSY-operator \(L_{2,1}\) from \(u_{1,1}\) and act with it on the unphysical solutions \(\tilde{u}_{1,1}\) and \(u_{1,0}\). As first result we obtain

\[
u_{2,1} = L_{2,1} \tilde{u}_{1,1} = \frac{1}{u_{1,1}} = \frac{u_{0,0}}{W(u_{0,0}, u_{0,1})}
\]

(A.4)

where (9) and (A.3) have been used. For the second function we find

\[
u_{2,0} = L_{2,1} u_{1,0} = \frac{1}{u_{0,0}} = \frac{1}{u_{0,0} u_{1,1}} L_{1,0}^+ u_{1,1} = \frac{1}{u_{0,0} u_{1,1}} L_{1,0}^+ L_{1,0} u_{1,0}
\]

\[
= (E_1 - E_0) \frac{1}{u_{0,0} u_{1,1}} u_{1,0} = (E_1 - E_0) \frac{u_{0,1}}{W(u_{0,0}, u_{0,1})}
\]

(A.4)
Here the operator \( L_{2,1} = -u_{1,1x}/u_{1,1} + \partial_x \) has been replaced by \( L^+_{1,0} = -u_{0,0x}/u_{0,0} - \partial_x \) with the help of \((1/u_{0,0})' = -u_{0,0}'/u_{0,0}^2\). Moreover, we have used \((\text{A.3})\), the factorization rule \( L^+_{1,0}L_{1,0} = h_0 - E_0 \) and the Schrödinger equation \( h_0u_{0,1} = E_1u_{0,1} \).

Assuming finally that the representations \((\text{A.1})\) and \((\text{A.2})\) are valid for \( u_{N,N-1} \) we prove them for \( u_{N+1,n} \) and \( u_{N+1,N} \).

We start with \( u_{N,N-1} \mapsto u_{N+1,N} \). To go from \( h_N \) to \( h_{N+1} \) only the linear (one-step) SUSY transformation \( L_{N+1,N} \) is required. Applying \((\text{A.4})\) and combining it with the normalization condition \( W(u_{N,N}, u_{N,N}) = 1 \) and the Crum-Krein formula \((\text{A.7})\) [or \((\text{45})\)] we find the equivalence chain

\[
u_{N+1,N} = L_{N+1,N} u_{N,N} = \frac{W(u_{N,N}, \bar{u}_{N,N})}{W(u_{N,N})} = \frac{1}{u_{N,N}} = \frac{W(u_{0,0}, \ldots, u_{0,N-1})}{W(u_{0,0}, \ldots, u_{0,N})}.
\]

Comparison with \((\text{A.2})\) shows that the proof is done.

The proof of the induction \( u_{N,n} \mapsto u_{N+1,n} \) is less obvious. In section \((\text{4.2})\) the linear intertwiners \( L_{m+1,m} \) have been build strictly incrementally from the corresponding ground state eigenfunctions \( u_{m,m} \) (of the Hamiltonians \( h_m \)) as transformation functions. Here, we need a more general non-incremental construction scheme. In order to facilitate it, we first introduce a very detailed notation for general polynomial intertwiners \( L_{k,0} \) indicating explicitly the energy levels of the transformation functions from which they are built. Based on the Crum-Krein formula \((\text{A.7})\) we set

\[
L_{k,0}^{(a_1, a_2, \ldots, a_k)} f := \frac{W(u_{0,a_1,1}, u_{0,a_2,1}, \ldots, u_{0,a_k,1})}{W(u_{0,a_1,1}, u_{0,a_2,1}, \ldots, u_{0,a_k,1})} f \quad a_i \neq a_j \neq a_k
\]

with \( a_i \in \mathbb{Z}^+ \) being any energy level numbers of the Hamiltonian \( h_0 \). The determinant structure of \((\text{A.5})\) immediately implies the generalized kernel property

\[
L_{k,0}^{(a_1, a_2, \ldots, a_k)} u_{0,n} = 0
\]

and the invariance of the operator \( L_{k,0}^{(a_1, a_2, \ldots, a_k)} \) with regard to permutations \( (a_1, a_2, \ldots, a_k) \mapsto \sigma(a_1, a_2, \ldots, a_k) \)

\[
L_{k,0}^{\sigma(a_1,a_2,\ldots,a_k)} = L_{k,0}^{(a_1,a_2,\ldots,a_k)}.
\]

Recalling that \((\text{A.5})\) can be built from a chain \( L_{k,k-1}^{(a_k)} L_{k-1,k-2}^{(a_{k-1})} \cdots L_{1,0}^{(a_1)} \) of linear intertwiners \( L_{m+1,m} \) we conclude that the ordering with regard to energy levels is inessential in the transformation chain and that we can split it into sub-chains with any permitted combination of levels

\[
\sigma(a_1, \ldots, a_k) = (b_1, \ldots, b_B, c_1, \ldots, c_C), \quad B + C = k
\]

\[
L_{k,0}^{(a_1, \ldots, a_k)} = L_{B+C,B}^{(c_1, \ldots, c_C)} L_{B,0}^{(b_1, \ldots, b_B)} = L_{C+B,C}^{(c_1, \ldots, c_C)} L_{C,0}^{(b_1, \ldots, b_B)}.
\]

Apart from this full commutativity of the transformations we note their associativity

\[
L_{m+3,m+2}^{(a_3)} L_{m+2,m+1}^{(a_2)} L_{m+1,m}^{(a_1)} = L_{m+3,m+2}^{(a_3)} L_{m+2,m+1}^{(a_2)} L_{m+1,m}^{(a_1)}.
\]

Commutativity and associativity can be used to re-arrange a sequence of transformations in any required order.

In accordance with the intertwiners \( L \) we denote eigenfunctions as

\[
u_{k,n}^{(a_1,a_2,\ldots,a_k)} := L_{k,0}^{(a_1,a_2,\ldots,a_k)} u_{0,n}, \quad a_i \neq n, \quad i = 1, \ldots, k.
\]
Another ingredient that we need is the representation

\[
W(u_{0,0}, \ldots, u_{0,N-1}) = (-1)^{N-1-n} \frac{W(u_{0,0}, \ldots, u_{0,n-1}, u_{0,n+1}, \ldots, u_{0,N-1}, u_{0,n})}{W_n(u_{0,0}, \ldots, u_{0,N-1})}
\]

\[
= (-1)^{N-1-n} L_{N-1,0}^{(0,\ldots,n-1,n+1,\ldots,N-1)} u_{0,n}
\]

\[
= (-1)^{N-1-n} (u_{0,n-1,n+1,\ldots,N-1}) =: v_{N-1,n}
\]

(A.11)

which immediately follows from the Crum-Krein formula (A.5) and definition (A.10).

From the physical solution \(v_{N-1,n}\) we build the operators \(\tilde{v}_{N,n}\) and the corresponding Hamiltonian \(h_{N-1}^{(0,\ldots,n-1,n+1,\ldots,N-1)}\) with

\[
L_{N,N-1}^{(n)+} := L_{N,N-1}^{(n)} [v_{N-1,n}] = -\frac{v_{N-1,n,x}}{v_{N-1,n}} + \partial_x
\]

\[
L_{N,N-1}^{(n)+} := L_{N,N-1}^{(n)+} [v_{N-1,n}] = -\frac{v_{N-1,n,x}}{v_{N-1,n}} - \partial_x
\]

(A.12)

and the corresponding Hamiltonian \(h_{N-1}^{(0,\ldots,n-1,n+1,\ldots,N-1)}\) with

\[
L_{N,N-1}^{(n)+} L_{N,N-1}^{(n)} = h_{N-1}^{(0,\ldots,n-1,n+1,\ldots,N-1)} = E_n.
\]

We start the proof of the induction \(u_{N,n} \mapsto u_{N+1,n}\) with the following transformations

\[
u_{N+1,n} = L_{N+1,N}^{(N)} u_{N,n} = C_{N,n} L_{N+1,N}^{(N)} W_n(u_{0,0}, \ldots, u_{0,N-1})
\]

\[
= C_{N,n} L_{N+1,N}^{(N)} v_{N-1,n}
\]

\[
= C_{N,n} \left[ -\frac{u_{N,N,x}}{u_{N,N} v_{N-1,n}} - \frac{v_{N-1,n,x}}{v_{N-1,n}} \right]
\]

\[
= C_{N,n} \frac{1}{u_{N,N} v_{N-1,n}} L_{N,N-1}^{(n)+} u_{N,N}.
\]

(A.14)

In order to obtain the operator product \(L_{N,N-1}^{(n)+} L_{N,N-1}^{(n)}\) we use (A.5) and the Crum-Krein formula (A.5)

\[
u_{N,N} = L_{N,0}^{(0,1,\ldots,N-1)} u_{0,N} = \frac{W(u_{0,0}, \ldots, u_{0,N})}{W(u_{0,0}, \ldots, u_{0,N-1})}
\]

\[
= L_{N,N-1}^{(n)} L_{N-1,0}^{(0,\ldots,n-1,n+1,\ldots,N-1)} u_{0,N}
\]

\[
= L_{N,N-1}^{(n)} L_{N-1,0}^{(0,\ldots,n-1,n+1,\ldots,N-1)}
\]

(A.15)

where

\[
u_{N-1,N}^{(0,1,\ldots,n-1,n+1,\ldots,N-1)} = L_{N-1,0}^{(0,1,\ldots,n-1,n+1,\ldots,N-1)} u_{0,N}
\]

\[
= \frac{W_n(u_{0,0}, \ldots, u_{0,N})}{W(u_{0,0}, \ldots, u_{0,N-1})}.
\]

(A.16)

This gives

\[
u_{N+1,n} = C_{N,n} \frac{1}{u_{N,N} v_{N-1,n}} L_{N,N-1}^{(n)+} u_{N,N}
\]

\[
= C_{N,n} \frac{1}{u_{N,N} v_{N-1,n}} L_{N,N-1}^{(n)+} L_{N,N-1}^{(n)} u_{N,N}
\]

\[
= C_{N,n} \frac{1}{u_{N,N} v_{N-1,n}} L_{N,N-1}^{(n)+} L_{N,N-1}^{(n)} u_{N,N}
\]

(A.17)

14) For \(C \neq 0\) holds \(L_{N,N-1}^{(n)+} [C v_{N,n}] = L_{N,N-1}^{(n)} [v_{N,n}]\) so that the sign factor \((-1)^{N-1-n}\) plays no role in the operator \(L_{N,N-1}^{(n)}\) itself.
where the last line has been obtained by expressing $u^{(0,1,...,n-1,n+1,...,N-1)}_{N-1,N}$, $u_{N,N}$ and $v_{N-1,n}$ via (A.10), (45) and (A.11) in terms of their Wronskian fractions. With (A.17) the proof is complete.
