(Dated: January 25, 2023)

The spatial covariant gravities provide a natural way to including odd-order spatial derivative terms into the gravitational action, which breaks the parity symmetry at gravitational sector. A lot of parity-violating scalar-tensor theories can be mapped to the spatial covariant framework by imposing the unitary gauge. This provides us with a general framework for exploring the parity-violating effects in primordial gravitational waves (PGWs). The main purpose of this paper is to investigate the polarization of PGWs in the spatial covariant gravities and their possible observational effects. To this end, we first construct the approximate analytical solution to the mode function of the PGWs during the slow-roll inflation by using the uniform asymptotic approximation. With the approximate solution, we calculate explicitly the power spectrum and the corresponding circular polarization of the PGWs analytically. It is shown that the new contributions to power spectrum from spatial covariant gravities contain two parts, one from the parity-preserving terms and the other from the parity-violating terms. While the parity-preserving terms can only affect the overall amplitudes of PGWs, the parity-violating terms induce nonzero circular polarization of PGWs, i.e., the left-hand and right-hand polarization modes of GWs have different amplitudes. The observational implications of this nonzero circular polarization is also briefly discussed.

I. INTRODUCTION

The inflation which took place at the early Universe has become a dominant paradigm in the standard cosmology [1–6]. In this paradigm, primordial density and gravitational-wave fluctuations are created from quantum fluctuations during the inflation process. The former provides primordial seeds for the formation of observed large-scale structure and creates the temperature anisotropy in the cosmic microwave background (CMB), which was already detected by various CMB experiments [7–10]. The primordial gravitational waves (PGWs), on the other hand, also produce distinguishable signatures in both the spectra of the CMB [11–15] and the galaxy shaped power spectrum [16–22]. In CMB, the PGWs can produce the TT, EE, BB, and TE spectra, but the TB and EB spectra vanish if the parity symmetry in gravity is respected [11–15]. These signatures are important targets of future CMB experiments [23–26]. Similarly, the PGWs also leave distinct imprints in the B-mode of the galaxy shaped power spectrum but with vanishing E-B correlation due to the parity conservation of the theory [16–22]. It is therefore expected that the future galaxy surveys could also provide invaluable information about the physics of PGWs [22, 27, 28].

In most of inflation models that produce PGWs, the theory of general relativity (GR) is assumed to describe the theory of gravity. Due to the parity symmetry of this theory, the PGWs have two polarization modes which share exactly the same statistical properties and the corresponding inflationary power spectra take the same form. If the parity symmetry is violated, however, the inflationary power spectra of right- and left-handed PGWs can have different amplitudes. The corresponding relative difference between the power spectra of right- and left-handed PGWs measures the level of the parity violation. In CMB, such parity violating effects can induce nonvanishing TB and EB correlation in CMB at large scales and thus the precise measurement of TB and EB spectra could be an important evidence of the parity violation of the gravitational interaction [29–33]. It is also proposed that the future ground- and space-based interferometers (such as LIGO/Virgo [34, 35], the Big Bang Observer [38], LISA and Taiji/Tianqin [36, 37], etc) are also able to detect or constrain the parity violating effects in the stochastic gravitational-wave background of primordial origin. In addition, parity-violating PGWs also leaves imprints on the large scale structure of the Universe [39] and sources nonzero E-B correlation in the galaxy shape power spectrum [22]. Thus the future galaxy surveys can provide an important approach for testing or constraining the parity violating effects in PGWs [22, 39].

Theoretically, gravitational parity violation has to somehow modify the theory of GR. This can be achieved by adding some parity-violating terms into the gravi-
tional action of GR. In fact, the gravitational terms with parity violation are ubiquitous in numerous candidates of quantum gravity, such as string theory, loop quantum gravity, and Horava-Lifshitz gravity. One important example is the Chern-Simons modified gravity, which modifies the GR by adding a gravitational Chern-Simons term, arising from string theory and loop quantum gravity [40, 41]. This theory has been extended to a chiral scalar-tensor theory by including the higher derivatives of the coupling scalar field [42]. On the other hand, by breaking the time diffeomorphism (or Lorentz symmetry) of the gravitational theory, one can naturally add parity-violating but spatial covariant terms into the gravitational action. This type of parity-violating theories includes Horava-Lifshitz gravities with parity violations [43–46] and more generally, the spatial covariant gravities [47–49]. Other parity-violating theories, to mention a few, include Nieh-Yan modified teleparallel gravity [52, 53], parity-violating symmetric teleparallel gravities [54, 55], and standard model extension [56–60], Holst gravity [61], etc.

In all these modified theories, a basic prediction of parity violation is the circular polarization of PGWs, i.e., the left-hand and right-hand polarization modes of GWs propagate with different behaviors. As we also mentioned in the above, such asymmetry between the left- and right-handed modes of PGWs can induce various observational or experimental effects in CMB, stochastic gravitational-wave background, and galaxy-shaped power spectrum. These phenomenological effects have motivated a lot of works in this directions (see Refs. [22, 43–45, 62–84] and references therein for example). It is worth noting that the gravitational-wave constraints on the parity violation in gravity have also been extensively explored in the literature by using the gravitational-wave data realized by LIGO/Virgo Collaboration [85–97].

Spatial covariant gravities is one of modified theory of GR, which breaks the time diffeomorphism of the gravity but respects spatial diffeomorphisms [47–50]. Such spatial covariance provides a natural way to incorporate the parity-violating terms into the theory [85]. With spatial covariance, the parity violation can be achieved by including the odd-order spatial derivatives into the gravitational action. It is shown in [47, 51] that the spatial covariant gravities can provide a unified description for a lot of scalar-tensor theory by imposing the unitary gauge, including those with parity violation, such as the Chern-Simons modified gravity, chiral scalar-tensor theory, Horava-Lifshitz gravities, etc. Therefore, the spatial covariant gravities can provide a general framework for us to explore the parity violating effects in PGWs. For this purpose, in this paper we study the circularly polarized PGWs in this theory of gravity with parity violation, and the possibility to detect the chirality of PGWs by future potential CMB observations and galaxy surveys.

This paper is organized as follows. In the next section, we present a brief introduction of the construction of the spatial covariant gravities and then discuss the associated propagation of GWs in the a homogeneous and isotropic cosmological background in Sec. III. In Sec. IV, we first derive the master equation that describes the propagation of GWs during inflation and construct the approximate analytical solution to the PGWs by using the uniform asymptotic approximation. With such approximate solution we then calculate explicitly the power spectrum and the polarization of PGWs during the slow-roll inflation. The effects of the parity violation in the CMB spectra and galaxy shaped spectrum, and their detectability have also been briefly discussed. The paper is ended with Sec. V, in which we summarize our main conclusions and provide some outlooks.

Throughout this paper, the metric convention is chosen as \((-\,,\,\,\,\,\,\,+\,\,\,\,\,\,+\,)\), and greek indices \((\mu, \nu, \cdots)\) run over 0, 1, 2, 3 and latin indices \((i, j, k)\) run over 1, 2, 3.

II. SPATIAL COVARIANT GRAVITIES

In this section, we present a brief introduction of the framework of the spatial covariant gravity, for details about this theory, see [47, 48] and references therein.

We first start with the general action of the spatial covariant gravity,

\[
S = \int dtd^3x N \sqrt{g} \mathcal{L}(N, g_{ij}, K_{ij}, R_{ij}, \nabla_i, \epsilon_{ijk}), \quad (2.1)
\]

where \(N\) is the lapse function, \(g_{ij}\) is the 3-dimensional spatial metric, \(K_{ij}\) is the extrinsic curvature of \(t = \text{constant}\) hypersurfaces,

\[
K_{ij} = \frac{1}{2N} (\partial_t g_{ij} - \nabla_i N_j - \nabla_j N_i), \quad (2.2)
\]

with \(N_i\) being the shift vector, \(R_{ij}\) the intrinsic curvature tensor, \(\nabla_i\) the spatial covariant derivative with respect to \(g_{ij}\), \(\epsilon_{ijk}\) being the total antisymmetric tensor. The most important feature of the spatial covariant gravity is that it is only invariant under the three-dimensional spatial diffeomorphism, which breaks the time diffeomorphism. Normally, the violation of the time diffeomorphism can lead to an extra degree of freedom, in addition to the two tensorial degree of freedom in GR. Indeed, it has been verified that the spatial covariant gravity described by the action (2.1) can propagate up to three dynamical degrees of freedom [48]. In [49, 50], the above action has also been extended by introducing \(\dot{N}\) in the Lagrangian through \(\dot{N}/N = \nabla_i N_i/N\). Since such terms does not contribute to the gravitational waves at quadratic order, we will not consider them in this paper.

There are a lot approaches to construct the gravitational theories with spatial covariance. In this paper, we adopt the approach used in [85] which constructs the Lagrangians of the theory by using the linear combinations of the extrinsic curvature \(K_{ij}\), intrinsic curvature \(R_{ij}\), as well as their spatial derivatives and derivatives of the spatial metric itself. Then, up to the fourth order in
TABLE I. The building blocks of spatial covariant gravities up to the fourth order in derivatives of $h_{ij}$, where $d_t$, $d_s$ are the number of time and spatial derivative respectively, and $d = d_t + d_s$ denotes the total numbers of time and spatial derivatives. Here $\omega_3(\Gamma)$ denotes the spatial gravitational Chern-Simons term, and $\omega_3(\Gamma) = \tilde{\epsilon}^{ijk}(\Gamma^m_{ij} g_{kn} + \frac{1}{2} \Gamma^m_{ij} g_{kn})$ with $\Gamma^m_{ij} = \frac{1}{2} g^{kn}(\partial_j g_{m} + \partial_j g_{ij} - \partial_m g_{ij})$ being the spatial Christoffel symbols. The terms in this Table is the same as those of Table I in [85] except the two new terms $\omega_3(\Gamma)$ and $\omega_3(\Gamma) K$.

| $d$ | $(d_t, d_s)$ | operators |
|-----|--------------|-----------|
| 0   | (0, 0)       | $K$       |
| 1   | (1, 0)       | $\mathcal{L}^{(1)}$ |
| 2   | (1, 1)       | $\mathcal{L}^{(2)}$ |
| 3   | (2, 0)       | $\mathcal{L}^{(3)}$ |
| 4   | (2, 2)       | $\mathcal{L}^{(4)}$ |

derivatives of $h_{ij}$, we have the building blocks as shown in Table. I that are all scalars under transformation of spatial diffeomorphisms. Then the general action of the gravitational part will be given by [85]

$$S_g = \int dt d^3 x \sqrt{g} N \left( \mathcal{L}^{(0)} + \mathcal{L}^{(1)} + \mathcal{L}^{(2)} + \mathcal{L}^{(3)} + \mathcal{L}^{(4)} \right)
\quad + \mathcal{L}^{(4)}(\Gamma), \quad (2.3)$$

where $\mathcal{L}^{(0)}$, $\mathcal{L}^{(1)}$, $\mathcal{L}^{(2)}$, $\mathcal{L}^{(3)}$, and $\mathcal{L}^{(4)}$ are the parity-preserving terms, which are given by

$$\mathcal{L}^{(0)} = c_1^{(0,0)}, \quad (2.4)
\mathcal{L}^{(1)} = c_1^{(1,0)} K, \quad (2.5)
\mathcal{L}^{(2)} = c_1^{(2,0)} K^{ij} K_{ij} + c_2^{(2,0)} K^2 + c_1^{(0,2)} R, \quad (2.6)
\mathcal{L}^{(3)} = c_1^{(3,0)} K^{ij} K_k^i K_j^k + c_2^{(3,0)} K^{ij} K_k^j K^i + c_3^{(3,0)} K^3
\quad + c_1^{(1,2)} \nabla^i \nabla^j K_{ij} + c_2^{(1,2)} \nabla^2 K + c_3^{(1,2)} R \nabla^i K_{ij}
\quad + c_4^{(1,2)} R K, \quad (2.7)
\mathcal{L}^{(4)} = c_1^{(4,0)} K^{ij} K^k K^{ij} + c_2^{(4,0)} K^{ijk} K^{jk} + c_1^{(0,4)} K
\quad + c_4^{(4,0)} K^{ij} K^k K^{ij} + c_4^{(4,0)} K^4
\quad + c_2^{(2,2)} \nabla^i K_{ij} \nabla^k K^{ij} + c_2^{(2,2)} \nabla^i K_{jk} \nabla^k K^{ij}
\quad + c_2^{(2,2)} \nabla^i K_{ij} \nabla^k K^j + c_2^{(2,2)} \nabla^j K_{ij} \nabla^k K^j
\quad + c_2^{(2,2)} \nabla^i K^{ij} \nabla^k K^j + c_2^{(2,2)} R_{ij} K^i K^j
\quad + c_2^{(2,2)} R_{ij} K^i K^j + c_8^{(2,2)} R_{ij} K^i K^j + c_9^{(2,2)} RK^2
\quad + c_1^{(0,4)} \nabla^i \nabla^j R_{ij} + c_2^{(0,4)} \nabla^2 R + c_3^{(0,4)} R \nabla^i R_{ij}
\quad + c_4^{(0,4)} R^2, \quad (2.8)$$

and $\mathcal{L}^{(3)}$ and $\mathcal{L}^{(4)}$ are parity-violating terms which are
given by

$$\mathcal{L}^{(3)} = c_1^{(2,1)} \tilde{\epsilon}^{ijk} K^i \nabla^j K^{kl} + c_1^{(3)} \omega_3(\Gamma), \quad (2.9)
\mathcal{L}^{(4)} = c_1^{(3,1)} \tilde{\epsilon}^{ijk} \nabla^m K^{ij} K^{mj} K^{kn} + c_2^{(3,1)} \tilde{\epsilon}^{ijk} \nabla^i K^{mj} K^{kn} N + \tilde{\epsilon}^{ij} \nabla^i K^{mj} K^{km}
\quad + c_3^{(1,3)} \tilde{\epsilon}^{ijk} \nabla^i K^{jk} K^{kl} + c_2^{(3,1)} \tilde{\epsilon}^{ijk} R^{it} \nabla^i K^{kl}
\quad + c_2^{(3,1)} \tilde{\epsilon}^{ijk} R^{it} K^{kl} + c_3^{(3,1)} \omega_3(\Gamma) K \quad (2.10)$$

All the coefficients like $c_i^{(d_t, d_s)}$ are functions of $t$ and $N$. Note that in Table. I and Eqs. (2.9) and (2.10), we add the spatial Chern-Simons term $\omega_3(\Gamma)$ and its coupling to $K$, which are absent in the original action in [85]. It is interesting to note that the above action reduces to GR if one imposes

$$c_1^{(2,0)} = c_1^{(0,2)} = c_2^{(2,0)} = \frac{M_\text{Pl}^2}{2}, \quad (2.11)$$

with all other coefficients $c_i^{(d_t, d_s)}$ being set to zero.

The spatial covariant gravity described in the above action can represent a very general framework for describing the propagations of GWs in the low-energy effective gravities with Lorentz or parity violation. To our knowledge, a lot of modified gravities can be casted in the framework of the spatial covariant gravity. In addition, it is shown that one in general can relate the spatial covariant gravity to the scalar-tensor theories in the unitary gauge [47, 51].

III. GWS IN SPATIAL COVARIANT GRAVITIES

Let us investigate the propagation of GWs in the spatial covariant gravities with the action given by (2.3).
We consider the GWs propagating on a homogeneous and isotropic background. The spatial metric in the flat Friedmann-Robertson-Walker universe is written as

\[ g_{ij} = a(\tau)(\delta_{ij} + h_{ij}(\tau, x^i)), \]  

(3.1)

where \( \tau \) denotes the conformal time, which relates to the cosmic time \( t \) by \( dt = a \, d\tau \), and \( a \) is the scale factor of the universe. Throughout this paper, we set the present scale factor \( a_0 = 1 \). \( h_{ij} \) denotes the GWs, which represents the transverse and traceless metric perturbations, i.e,

\[ \partial^i h_{ij} = 0 = h_i^i. \]  

(3.2)

To proceed one can substitute the above spatial metric into the action (2.3) and expand it to the second order in \( h_{ij} \). Here we write the quadratic action in the form as shown in [85],

\[ S^{(2)} = \int dt dx \frac{a^3}{2} \left[ G_0(t) h_{ij}^2 + G_1(t) \epsilon^{ijk} \frac{1}{a} \partial_j h_k - G_2(t) h_{ij} \frac{\Delta}{a^2} h_{ij} + \mathcal{W}_0(t) h_{ij} \frac{\Delta}{a^2} h_{ij} + \mathcal{W}_1(t) \epsilon^{ijk} h_{li} \frac{1}{a^2} \partial_j h_k - \mathcal{W}_2(t) h_{ij} \frac{\Delta^2}{a^4} h_{ij} \right], \]

(3.3)

where \( G_n \) and \( \mathcal{W}_n \) are given by [85]

\[ G_0 = \frac{1}{2} \left[ c_1^{(2,0)} + 3(3c_1^{(3,0)} + c_2^{(3,0)}) H + (3c_1^{(4,0)} + 2c_2^{(4,0)} + 3c_3^{(4,0)}) H^2 \right], \]

(3.4)

\[ G_1 = \frac{1}{2} \left[ c_1^{(2,1)} - c_1^{(3,1)} - 2c_2^{(3,1)} - 3c_3^{(3,1)} \right] H, \]

(3.5)

\[ G_2 = \frac{1}{2} c_1^{(2,2)}, \]

(3.6)

\[ \mathcal{W}_0 = \frac{1}{2} \left[ c_1^{(0,2)} + \frac{1}{2} c_3^{(1,2)} + \frac{1}{2} \left( 3c_3^{(1,2)} + 6c_4^{(1,2)} + 2c_6^{(2,2)} + 3c_8^{(2,2)} \right) H \right. \]

\[ + \left. \frac{1}{2} \left( 4c_6^{(2,2)} + 6c_7^{(2,2)} + 9c_8^{(2,2)} + 18c_9^{(2,2)} \right) H^2 + \frac{1}{2} \left( 2c_6^{(2,2)} + 3c_8^{(2,2)} \right) H \right], \]

(3.7)

\[ \mathcal{W}_1 = \frac{1}{4} \left[ c_1^{(1,3)} + c_2^{(1,3)} \right] \]

(3.8)

\[ \mathcal{W}_2 = - \frac{1}{2} c_3^{(0,4)}. \]

(3.9)

In above a dot denotes the derivative with respect to the cosmic time \( t \) and \( H = \dot{a}/a \) is the Hubble parameter. We consider the GWs propagating in the vacuum, and ignore the source term. Varying the action with respect to \( h_{ij} \), one can derive the equation of motion for \( h_{ij} \) as

\[ \left( G_0 - G_2 \frac{\partial^2}{a^2} \right) h''_{ij} + \left[ 2\mathcal{H} G_0 + G_0' - G_2 \frac{\partial^2}{a^2} \right] h'_{ij} \]

\[ - \left[ \mathcal{W}_0 - \mathcal{W}_2 \frac{\partial^2}{a^2} \right] \partial^2 h_{ij} \]

\[ + \epsilon_{ijk} \frac{\partial}{a} \left[ G_1 \partial^2 \right] \mathcal{H} G_1 + \mathcal{G}_1 \partial^2 \mathcal{H} - \mathcal{W}_1 \partial^2 \right] h^k_j = 0, \]

(3.10)

where \( \mathcal{H} \equiv a'/a \) and a prime denotes the derivative with respect to the conformal time \( \tau \).

\[ \text{IV. POLARIZATION OF PGWS} \]

**A. Equation of motion for GWs**

In order to study the propagation of GWs in the spatial covariant gravities, it is convenient to decompose the GWs into the circular polarization modes. To study the evolution of \( h_{ij} \), we expand it over spatial Fourier harmonics,

\[ h_{ij}(\tau, x^i) = \sum_{A=R,L} \int \frac{d^3k}{(2\pi)^3} h_A(\tau, k^i) \epsilon^{ijk} \epsilon_{ij}^A(k^i), \]

(4.1)

where \( \epsilon_{ij}^A \) denotes the circular polarization tensors and satisfy the relation

\[ \epsilon^{ijk} n_i \epsilon_{kl}^A = i \rho_A \epsilon_{jk}^A, \]

(4.2)

with \( \rho_R = 1 \) and \( \rho_L = -1 \). We find that the propagation equations of these two modes are decoupled, which can be casted into the form [85]

\[ h''_A + (2 + \Gamma_A) \mathcal{H} h_A + \omega_A^2 h_A = 0, \]

(4.3)

\[ ^1 \text{In } \mathcal{W}_1 \text{ we add the contributions from the two new terms } \omega_3(\Gamma) \text{ and } \omega_3(\Gamma) \Delta. \]
where
\[ \mathcal{H} \Gamma_A = \left[ \ln \left( G_0 + \rho_A G_1 k^2 a^2 \right) \right] \frac{\kappa^2}{k^2}, \]
\[ \omega_A^2 = \frac{W_0 + \rho_A W_1 k^2 + W_2 k^2}{G_0 + \rho_A G_1 k^2 + G_a k^2 a^2}. \]

With this equation, the propagation properties of GWs in the cosmological background have been explored in details in [85]. Some conditions to make the two polarization modes propagate in the same speed have been considered and a lot of parity-violating gravities with both of polarization modes propagating in the speed of light have been also identified in [85]. In the above equation, the derivations of the spatial covariant gravities from GR are fully characterized by the quantities \( \Gamma_A \) and \( \omega_A^2 \). The former represents the corrections to the damping rate which modifies the amplitude damping rate of the GWs during their propagations in the cosmological background, and the latter is the modified dispersion relation of GWs which leads to a phase shifting of GWs from distant sources.

For later convenience of calculating the primordial power spectra of GWs, let us introduce a new variable
\[ u_A = \sqrt{2} z h_A, \]
with
\[ z = a \sqrt{G_0 + \rho_A G_1 k^2 a^2 + G_a k^2 a^2}. \]

Then the equation of motion (4.3) can be rewritten in the form
\[ u_A'' + \left( \omega_A^2 - \frac{z''}{z} \right) u_A = 0, \]
and we expect the derivations from GR are small such that
\[ \Gamma_A \ll 1, \quad \left| \omega_A^2 \frac{k^2}{a^2} - 1 \right| \ll 1. \]

Thus we can consider all the new effects on GWs beyond GR as small corrections to the standard GR result. In this way, we are able to expand \( \omega_A^2 \) and \( \frac{z''}{z} \) as
\[ \omega_A^2 \approx \frac{W_0}{G_0} + \rho_A \frac{W_1}{G_0} k^2 + \frac{W_2}{G_0} k^2 a^2, \]
\[ \frac{z''}{z} \approx \left( 1 - \frac{1}{2} \frac{\rho A G_1 k^2}{G_0 a^2} - \frac{G_2 k^2}{G_0 a^2} \right) \frac{a''}{a} + \frac{1}{2} \left( \frac{G_0''}{G_0} + \rho_A G_1 k^2 a^2 + G_2 k^2 a^2 \right) \frac{a''}{a} + \frac{G_0''}{G_0} - \frac{G_2 k^2 a^2}{G_0 a^2}. \]

Note that in the above expansion, we only consider the first-order terms of each coefficients, i.e., \( 1 - W_0/G_0, W_1, \]
\( G_1, W_2, G_2, G_0' \), and \( G_0'' \).

In this article, we consider the PGWs during the inflationary stage, and assume that the background evolution during the inflation is slowly varying. With this consideration, we can treat all the coefficients \( G_0, G_1, G_2, W_0, W_1, \) and \( W_2 \) as slowly varying quantities. Then one is able to expand the modified dispersion relation \( \omega_A^2 \) in (4.10) and effective time-dependent mass term \( z''/z \) in (4.15) in terms of the slow-rolloff quantities as
\[ \omega_A^2 \approx \frac{W_0}{G_0} - \rho_A \frac{W_1}{G_0} H k^2 \]
\[ + \frac{W_2 - G_2 H^2 k^2}{G_0} k^2, \]
and
\[ \frac{z''}{z} \approx \frac{1}{k^2} \left( 2 + 3 \epsilon_1 + \frac{3 H G_0' + \dot{G}_0}{2 H^2 G_0} \right) \]
\[ + \frac{k}{\tau} \frac{2 H G_2 - H G_1 - \ddot{G}_1}{2 H G_0} \]
\[ - k^2 \frac{2 H^2 G_1 - H \dot{G}_1 - \ddot{G}_1}{2 G_0}. \]

It is worth noting that, in order to obtain the above expansions, we have used the relation
\[ a \simeq 1 + \frac{\epsilon_1}{\tau H}, \]
with \( \epsilon_1 = -\dot{H}/H^2 \).

With the expressions of \( z''/z \) and \( \omega_A^2/k^2 \), one observes that the equation of motion in Eq.(4.8) can be casted into the form
\[ u_A'' + \left( - \frac{v^2}{k^2 a^2} - \rho_A \frac{d_{-1}}{k^2} + d_0 \right) k^2 u_A = 0, \]
where
\[ v^2 = \frac{9}{4} + 3 \epsilon_1 + \frac{3 H G_0' + \dot{G}_0}{2 H^2 G_0}, \]
\[ d_{-1} = \frac{2 H^2 G_1 - H \dot{G}_1 - \ddot{G}_1}{2 G_0}, \]
\[ d_0 = \frac{W_0}{G_0} + \frac{2 H^2 G_2 + H \dot{G}_2 - \ddot{G}_2}{2 G_0}, \]
\[ d_1 = \frac{W_1 - G_1}{G_0} H, \]
\[ d_2 = \frac{W_2 - G_2 H^2}{G_0}, \]
and all these coefficients are slowly varying and dimensionless. Obviously, this equation does not have analytical solutions even if one treats all the slowly varying quantities as constants. In order to obtain its solution, we have to consider some approximations. In this paper, we will consider the uniform asymptotic approximation,
which is developed in a series of papers for a better treatment to equations with turning points and poles. This approximation has been widely applied in calculating primordial spectra for various inflation models [99-103] and applications in studying the reheating process [104] and quantum mechanics [105]. In the following subsections, we apply this approximation to construct the approximate solution of (4.15) and calculate the corresponding primordial tensor power spectra in the spatial covariant gravities.

B. Uniform asymptotic approximation

In this subsection, we employ the uniform asymptotic approximation method to construct the approximate asymptotic solutions. Most of the expressions and results used here can be found in [84, 99, 100, 102, 103].

In the uniform asymptotic approximation, it is convenient to write the equation of motion (4.15) in the following standard form [98, 99, 103],

\[
\frac{d^2u_A(y)}{dy^2} = [g(y) + q(y)]u_A(y),
\]

(4.21)

where \(y = -k\tau\) is a dimensionless variable and

\[
g(y) + q(y) \equiv \frac{v_1^2 - \frac{1}{2}}{y^2} + \frac{\rho_A d_{-1}}{y} - d_0 + \rho_A d_1 y - d_2 y^2.
\]

(4.22)

In general, \(g(y)\) and \(q(y)\) have two poles (singularities): one is at \(y = 0^+\) and the other is at \(y = +\infty\). In the uniform asymptotic approximation, in order to make the approximate solution being valid around the poles, one has to ensure that the error control function associated with the approximate solution to be convergent. For the equation of motion in (4.21) with \(g(y) + q(y)\) given by (4.22), it is shown in [99] that in order to make its error control function to be convergent around the second-order pole at \(y = 0^+\), one has to choose,

\[
q(y) = -\frac{1}{4y^2}.
\]

(4.23)

Then \(g(y)\) is given by

\[
g(y) = \frac{v_1^2}{y^2} + \frac{\rho_A d_{-1}}{y} - d_0 + \rho_A d_1 y - d_2 y^2.
\]

(4.24)

Except for the two poles at \(y = 0^+\) and \(y = +\infty\), \(g(y)\) may also have a single zero in the range \(y \in (0, +\infty)\), which called a single turning point of \(g(y)\). Since in GR limit, we have \(v_1^2 \simeq \frac{3}{4} + 3c_1, d_0 = 1, \) and \(d_{-1} = 0 = d_1 = d_2\), we expect all the new terms with coefficients \(a_{-1}, d_1, \) and \(d_2\) can be considered as small corrections. With this consideration and solving the equation \(g(y) = 0\), we obtain the turning point,

\[
y_0^A \simeq \frac{v_1}{\sqrt{d_0}} + \rho_A d_{-1} + \rho_A d_1 v_1^2 - d_2 v_1^3.
\]

(4.25)

In deriving the above expression, we have directly used \(d_0 = 1\) in the second term since \(d_0 - 1 \simeq \frac{v_1}{d_0} - 1 + \frac{2d_2 - 4}{d_0^2} - \frac{g}{2d_0} \) is a small corrections as well. In the uniform asymptotic approximation, the approximate solution depends on the type of turning point. The turning point \(y_0\) is a single root of the equation \(g(y) = 0\), which also called single turning point as well. Thus, in the following discussion, we will discuss the solution around this single turning point in details.

For the single turning point \(y_0\), the approximate solution of equation of motion around this turning point can be expressed in terms of Airy-type functions as [99]

\[
u_A = \alpha_0 \left( \frac{x}{y(y)} \right)^{1/4} \text{Ai}(x) + \beta_0 \left( \frac{x}{y(y)} \right)^{1/4} \text{Bi}(x),
\]

(4.26)

where \(\text{Ai}(x)\) and \(\text{Bi}(x)\) are the Airy functions, \(\alpha_0\) and \(\beta_0\) are two integration constants, \(x\) is the function of \(y\) and the form of \(x(y)\) is given by [99]

\[
x(y) = \begin{cases} 
\left( -\frac{3}{2} \int_{y_0}^y \sqrt{g(y')} dy' \right)^{2/3}, & y \leq y_0, \\
\left( \frac{3}{2} \int_{y_0}^y \sqrt{-g(y')} dy' \right)^{2/3}, & y \geq y_0. 
\end{cases}
\]

(4.27)

As shown in [98, 99], the above solution is not only valid around the turning point, but valid in the whole domain \(y \in (0, +\infty)\). It is shown in [98, 99] that with the choice of \(q(y)\) given in (4.23), the error control function of the approximate solution of (4.26) is convergent even around the two poles \(y = 0^+\) and \(y = +\infty\). With this solution, we need to determine the coefficients \(\alpha_0\) and \(\beta_0\) by matching it with the two boundary conditions. One requires the mode function \(u_A\) satisfies the following normalization condition, i.e.,

\[
\frac{i}{\hbar} (u_A^* u_A - u_A u_A^*) = 1,
\]

(4.28)

where \(u_A^*\) denotes the complex conjugate of the mode function \(u_A\). The second boundary condition that fixes the mode function \(u_A\) completely comes from the initial condition in the limit \(y \to +\infty\), which corresponds to the assumption that the universe was initially in an adiabatic vacuum,

\[
limit_{y \to +\infty} u_k(y) \simeq \frac{1}{\sqrt{2\omega_A}} e^{-i \omega_k \tau} = \sqrt{\frac{1}{2k}} \left( \frac{1}{-g} \right)^{1/4} \exp \left( -i \int_{y_1}^y \sqrt{-g} dy \right).
\]

(4.29)

When \(y \to +\infty\), we note that \(\xi(y)\) is very large and negative. In this limit, the asymptotic form of the Airy functions read

\[
\text{Ai}(-x) = \frac{1}{\pi^{1/4}} \cos \left( \frac{2}{3} x^{3/2} - \frac{\pi}{4} \right),
\]

(4.30)
These asymptotic forms indicate that only the growing modes of the Airy function, becomes very large and positive, allowing the use of the following asymptotic forms

\[
\text{Ai}(x) = \frac{1}{2\pi^{1/2}x^{1/4}} \exp\left(-\frac{2}{3}x^{3/2}\right),
\]

\[
\text{Bi}(x) = -\frac{1}{\pi^{1/2}x^{1/4}} \sin\left(\frac{2}{3}x^{3/2} - \frac{\pi}{4}\right).
\]

The power spectra of PGWs are then given by

\[
P_T^A = \frac{k^2}{\pi^2} \frac{1}{z^2} \nu_t \exp\left(2 \int_y^{y_0} dy \sqrt{g(y)}\right)
\]

\[
\approx \frac{H^2}{18\pi^2 e^{4G_0}} \left[1 + \left(2 \ln 2 - \frac{8}{3}\right) \epsilon_1 + \frac{(3 \ln 2 - 1)G_0}{3HG_0}\right]
\]

\[
+ \frac{\pi \rho_A(9d_1 + 8d_{-1})}{16} - \frac{9d_2}{4}.
\]

Note that in estimation the above integral, we take the limit \( y \to 0^+ \) and the detail calculation of the integral of \( \sqrt{g} \) is presented in Appendix A. Obviously, the power spectra can be modified due to the presence of both the parity-preserving terms and parity-violating terms in the gravitational action (2.3). It is easy to check that when one takes \( G_0 = M_p^2/4 \) and \( d_{-1} = d_1 = d_2 = 0 \), the standard GR result can be recovered. The parity-preserving terms can only affect the overall amplitude of both the left- and right-handed polarization modes of GW, which are related to the quantities \( G_0 \) and \( d_2 \) in the above expression. The relevant terms in the gravitational action are those with coefficients \( c_1^{(2,0)} \), \( c_1^{(3,0)} \), \( c_2^{(3,0)} \), \( c_1^{(4,0)} \), \( c_2^{(4,0)} \), \( c_3^{(4,0)} \), \( c_1^{(2,2)} \), and \( c_0^{(0,4)} \). The parity-violating terms, on the other hand, affect the amplitudes of left- and right-handed polarization modes of GW in different ways. For positive value of \( 9d_1 + 8d_{-1} \) in the above expression, the parity violation trends to enhanced (suppress) the power spectra of the right (left) -handed modes. This effect is related to those terms with coefficients \( c_1^{(2,1)} \), \( c_1^{(3,1)} \), \( c_2^{(3,1)} \), \( c_3^{(3,1)} \), \( c_1^{(1,3)} \), \( c_2^{(1,3)} \), \( c_3^{(1,3)} \), and \( c_3^{(1,3)} \) in the gravitational action (2.3).

As expected, the degree of the circular polarization \( \Pi \) only depends on the parity-violating terms in the gravitational action. It is not difficult to check that the above expression can exactly reduce to the cases of Chern-Simons modified gravity \([81]\), chiral scalar-tensor theory \([84]\), and Havara-Lifshitz gravity. It is important to mention here that, in our treatment, we have assumed that all the new

Combining the initial condition and the approximate analytical solution, we obtain

\[
\alpha_0 = \sqrt{\frac{\pi}{2k}} e^{\frac{x}{4}}, \quad \beta_0 = i \sqrt{\frac{\pi}{2k}} e^{\frac{3x}{4}}.
\]

In Fig. 1, we plotted the time evolution of the power spectra \(|k^{3/2}u_A/(z_t H)|^2\) for both the uniform asymptotic solutions and numerical solutions of the right-handed and the left hand modes respectively. We also displayed the cases in GR for comparison. From this figure, one can see clearly that our analytical solutions are extremely close to the numerical ones, and even are not distinguishable from the numerical ones.

C. Power spectra and circular polarization of PGWs

With the above approximate solutions of the PGWs, we are able to calculate the corresponding primordial power spectra for each polarization modes of the PGWs in the limit \( y \to 0 \). Their power spectra is normally computed via

\[
P_T^L = \frac{2k^3}{\pi^2} \left| \frac{u_L(y)}{z} \right|^2,
\]

\[
P_T^R = \frac{2k^3}{\pi^2} \left| \frac{u_R(y)}{z} \right|^2.
\]

In the limit \( y \to 0^+ \), the variable \( \xi(y) \), which is the argument of the Airy function, becomes very large and positive, allowing the use of the following asymptotic forms

\[
\text{Ai}(x) = \frac{1}{2\pi^{1/2}x^{1/4}} \exp\left(-\frac{2}{3}x^{3/2}\right),
\]

\[
\text{Bi}(x) = -\frac{1}{\pi^{1/2}x^{1/4}} \sin\left(\frac{2}{3}x^{3/2} - \frac{\pi}{4}\right).
\]

These asymptotic forms indicate that only the growing mode of \( u_A(y) \) is relevant in the limit \( y \to 0 \). Thus the approximate solution near the pole \( y = 0^+ \) can be expressed in the form

\[
u_A(y) \approx \beta_0 \left(\frac{1}{\pi^2 g(y)}\right)^{1/4} \exp\left(\int_y^{y_0} dy \sqrt{g(y)}\right)
\]

\[
= i \frac{1}{\sqrt{2k}} \left(\frac{1}{g(y)}\right)^{1/4} \exp\left(\int_y^{y_0} dy \sqrt{g(y)}\right).
\]
FIG. 1. The uniform asymptotic approximate solutions of mode functions \( \left| k^{3/2} u_A / (z_i H) \right|^2 \) (solid curves) and the corresponding numerical solutions (dotted curves). Left panel presents the solution of the left hand mode while the right panel presents the right hand mode. In each panel, the solid curves with blue color corresponds to the solution for case of general relativity, and green and darker yellow colors correspond to the spatial covariant gravities with different values of the parity-violating parameters. The numerical solution associated with each analytical solutions are presented by the red dotted curves.

effects from spatial covariant gravities are considered as small corrections. In this sense, we observe that the degree of the circular polarization \( \Pi \) is small due to the suppressing parameter \( |d_{\perp}|, |d_{\perp}e| < \mathcal{O}(1) \). In Fig. 2, we plotted the the analytical expression of the circular polarization \( \Pi \) in (4.38) (the solid and blue curves) and the corresponding numerical results (the dotted and red curves). From this figure, one can see clearly how well the numerical results are approximated by our analytical ones.

D. Detectability of the parity-violating effects

As we mentioned in the introduction, the parity-violating effect in PGWs, which is measured by the observable \( \Pi \), can produce a lot of observational information in CMB and galaxy surveys.

In CMB, one important effect is the induction of nonzero the TB and EB spectra in the CMB data. This implies that one can probe the parity violation by measuring the CMB EB and TB angular cross-correlators. However, as analyzed in [43] (see also [106]), such proposal is only optimistic when \( \Pi > \mathcal{O}(0.5) \), especially considering that the tensor-to-scalar ratio has been constrained to be \( r < 0.036 \) at 95\% confidence level in Ref. [107]. That a more stringent constraint has been reported from a combined analysis of newly released dataset including CMB and GW data [108]. Therefore, it seems very difficult to detect these effects in the future CMB experiments. According to the analysis in [39], the main difficulty comes from the two-dimensional projection of CMB, which suppresses the parity-violating signal due to approximate reflective symmetries, and confuses the tensor modes with scalar ones, leading to additional noise contributions. Possible ways for bypassing such challenge are proposed. The first one is to consider the three-points or even high-order correlators, such as the primordial bispectra and trispectra and their signatures in CMB [65, 69]. Another way is to search the tensor fossil effects due to parity violation in the statistics of the large-scale structure in future galaxy surveys [39]. These two topics are obvious out the scope of then current paper and we leave them for our future works.

Another proposal for detecting primordial parity-violating effects is to consider the imprints of circular polarization on the galaxy intrinsic alignments [69]. Similar to CMB, the circular polarization \( \Pi \) can directly induce a distinctive imprint in the galaxy shape spectrum, i.e., the nonzero EB correlation in the shape spectrum. Considering such signature can not be produced by the scalar modes, any signature of EB correlation in the future galaxy surveys would be a smoking gun for parity violation in PGWs, as mentioned in [69].

V. CONCLUSION AND OUTLOOK

The spatial covariant gravities can provide a unified description for a lot of scalar-tensor theories in the unitary gauge. Such framework breaks the time diffeomorphism of the gravity but respects spatial diffeomorphisms, so that one is able to to include the parity violating odd-order spatial derivative terms but with spatial covariance into the gravitational action. It is also shown in [47, 51] that a lot of parity-violating theories in the unitary gauge can be mapped to spatial covariant gravities. In this paper, we study the circular polarization of PGWs in the spatial covariant gravities and discuss its possible observational signatures. For this purpose we first solve the evolution of PGWs during slow-roll inflation by applying the uniform asymptotic approximation to the equations of motion for the PGWs. Using this approximation, we construct the approximate analytical solutions to the PGWs during the slow-roll inflation, with which we calculate explicitly both the power spectra for the two po-
lariation modes and the corresponding degree of circular polarization of PGWs in the spatial covariant gravities. It is shown that with the presence of the parity violation, the power spectra of PGWs are slightly modified and the degree of circular polarization becomes nonzero. The magnitude of the degree circular polarization directly depends on the parity-violating terms in the gravitational action (2.3), which are expected to be quite small due to the suppression of \( d_{-1}, d_1 < O(1) \). This implies very difficult to detect or effectively constrain the theories by using the TE and EB power spectra of future CMB data. The possible signatures of the circular polarization of PGWs in non-Gaussianities, large-scale structure, and EB correlation in the galaxy-shaped power spectrum are also briefly discussed.

Our work can be improved in several aspects. First, in the current study, we have not yet considered the effects of parity violation arising from the spatial covariant gravities in the non-Gaussianities of PGWs. According to the analysis in [72], the parity-violating effects in the tensor-tensor-scalar bispectrum could be large enough and detectable in the future CMB data. Thus, it is interesting to explore further whether the parity-violating terms in spatial covariance gravities could lead to any possible observational signatures in the non-Gaussianities of PGWs. Second, the parity-violating effects in primordial bispectrum and trispectrum of PGWs can also leave imprints in the statistic large scale structure [39] as well as the EB correlation in galaxy shape power spectrum [22]. We would like to come back to these topics in our future works.

Appendix A: Calculation of integral of \( \sqrt{g} \) in eq. (4.36)

In this appendix, we present the calculation of the following integral,

\[
\int_y^{y_0} dy' \sqrt{g(y')}.
\]

(A.1)

For this purpose, we can write the function \( g(y) \) in the following form

\[
g(y) = \frac{y_0 - y}{y^2}(a_0 + a_1 y + a_2 y^2 + a_3 y^3).
\]

(A.2)

Here the coefficients \( a_0, a_1, a_2, \) and \( a_3 \) are determined by comparing the above form with (4.24), which leads to

\[
a_0 = d_0 y_0 - d_{-1} \rho_A - d_1 \rho_A y_0^2 + d_2 y_0^3,
\]

(A.3)

\[
a_1 = d_0 - d_1 \rho_A y_0 + d_2 y_0^2,
\]

(A.4)

\[
a_2 = -d_1 \rho_A + d_2 y_0,
\]

(A.5)

\[
a_3 = d_2.
\]

(A.6)

It is evident that the magnitude of the coefficients \( a_2 \) and \( a_3 \) are determined by \( O(d_1, d_2) \), which can be treated as small corrections of the new terms beyond GR in spatial covariant gravity. Thus we can expand \( \sqrt{g(y)} \) by treating \( a_2 \) and \( a_3 \) as small perturbations. Then we have

\[
\sqrt{g(y)} \simeq \frac{\sqrt{(y_0 - y)(a_0 + a_1 y)}}{y}
\]
\[ I_0 = \sqrt{a_1} y_0 \lim_{x \to 0} \int_{x}^{1} \frac{\sqrt{(-x')'(b_0 + x')}}{x'} dx' \]

\[ = \sqrt{a_1} y_0 \left[ (1 - b_0) \arccsc(\sqrt{1 + b_0}) \right. \]

\[ + \sqrt{b_0} \ln \frac{4b_0}{(1 + b_0)x} - \sqrt{b_0}, \quad (A.9) \]

\[ I_1 = \frac{a_3 y_0^3}{2\sqrt{a_1}} \lim_{x \to 0} \int_{x}^{1} \frac{\sqrt{(-x')'(c_0 + x')}}{b_0} dx' \]

\[ = \frac{a_3 y_0^3}{48\sqrt{a_1}} \left[ \sqrt{b_0}(-3 + 4b_0 - 15b_0^2 + 6c_0 + 18b_0c_0) \right. \]

\[ + 3(1 - 2b_0 + 5b_0^2 + 2c_0 - 6b_0c_0) \]

\[ \times (1 + b_0) \arccsc(\sqrt{1 + b_0}), \quad (A.10) \]

with \( x \equiv y/y_0 \) and

\[ b_0 \equiv \frac{a_0}{a_1 y_0}, \quad (A.11) \]

\[ c_0 \equiv \frac{a_2}{a_3 y_0}. \quad (A.12) \]
