ABSTRACT

A standardised, single-centre cross-sectional imaging protocol was utilised to investigate cortical grey matter and cerebral white matter alterations in 36 poliomyelitis survivors in contrast to healthy individuals and patients with amyotrophic lateral sclerosis (ALS) as a 'disease-control' group. T1-weighted imaging and 32-direction diffusion tensor imaging data were obtained on a 3 Tesla Philips Achieva MRI system, using an IR-SPGR sequence and SE-EPI sequence respectively. Raw region-of-interest data and percentage change with respect to reference estimated marginal mean values are presented for grey and white matter metrics in key anatomical regions. Poliomyelitis survivors exhibit no frank grey or white matter degeneration. To the contrary, increased partial volumes can be detected in the brainstem, cerebellum and occipital lobes compared to healthy individuals. Higher fractional anisotropy was also noted in the corticospinal tracts, cerebellum, bilateral mesial temporal lobes and inferior frontal brain regions in poliomyelitis survivors in contrast to controls. Anatomical patterns of superior integrity

metrics in polio survivors were concordant with anatomical regions of focal degeneration in ALS. Our imaging data indicate cortical and white matter reorganisation in polio survivors, which may be interpreted as compensatory adaptation to severe lower motor neuron injury acquired in infancy.

|----------------------------------|----------------------------------------------------------|
| Specific subject area            | MRI, Grey matter ROI, White matter ROI, Subcortical volumetry, Poliomyelitis |
| Type of data                     | Raw volumetric data, Estimated Marginal Means plots, Box plots, Radar graphs |
| How data were acquired           | Imaging data were acquired on a Philips Achieva 3T MRI scanner with an 8-channel head coil. |
| Data format                      | The partial volumetric profiles of cortical grey matter regions are presented as raw data and percentage change with reference to healthy controls is reported adjusted for age, gender, education and total intracranial volumes. Region-of-interest fractional anisotropy (FA), axial diffusivity (AD), and radial diffusivity (RD) values are reported as raw values and percentage change presented with respect to controls adjusted for age, gender and education. |

**Parameters for data collection**

- T1-weighted data: 3D Inversion Recovery prepared Spoiled Gradient Recalled echo (IR-SPGR) sequence: spatial resolution: $1 \times 1 \times 1$ mm, Field of view: $256 \times 256 \times 160$ mm, repetition time= 8.5 ms, Echo time = 3.9 ms, Inversion time =1060 ms, flip angle = 8°. SENSE factor = 1.5, sagittal acquisition; 256 slices.
- Diffusion Tensor Imaging data: spin-echo planar imaging (SE-EPI) sequence, 32-direction SE-EPI sequence. Field of view: $245 \times 245 \times 150$ mm, spatial resolution = 2.5 mm$^3$, 60 slices, repetition time / Echo time = 7639/59 ms.

**Description of data collection**

- Data were collected on a 3 Tesla MRI system. Demographic variables were recorded before the MRI scan, and a standardised neurological examination was performed on the day of the MRI.

**Data source location**

- Institution: Computational Neuroimaging Group (CNG), Trinity Biomedical Sciences Institute, Trinity College Dublin
- City/Town/Region: Dublin
- Country: Ireland

**Data accessibility**

- Raw imaging metrics are available online at Mendeley Data; https://data.mendeley.com/datasets/dys423mzjp/1

### Value of the data

- Quantitative radiological data from poliomyelitis survivors allow the interpretation of imaging data in other lower motor neuron conditions
- White matter integrity metrics in polio survivors permits the juxtaposition of white matter measures in upper motor neuron conditions
- This dataset can be utilised for meta-analyses across multiple data sources
- Radiological data from polio survivors helps the validation of cerebral compensation studies in spinal conditions
- Grey and white matter data from healthy controls may be utilised for the interpretation of findings in other neurological conditions
1. Data Description

Region of interest quantitative imaging data is presented in a cohort of poliomyelitis survivors [2]. We present both grey and white matter imaging metrics in 36 poliomyelitis survivors who underwent magnetic resonance imaging using a standardised imaging protocol. To aid data interpretation, imaging data from healthy controls (HC, $n = 117$) and patients with amyotrophic lateral sclerosis (ALS, $n = 88$) were also acquired. Imaging metrics from poliomyelitis survivors and HC cohorts are available online at Mendeley Data; [2, http://dx.doi.org/10.17632/dys423mzjp.1

White matter integrity was evaluated using multiple diffusivity metrics; fractional anisotropy (FA), axial diffusivity (AD) and radial diffusivity (RD). In sharp contrast to other motor neuron diseases (MND), there is a paucity of imaging studies undertaken in polio survivors [3-5]. Existing imaging studies in motor neuron disease primarily focus on amyotrophic lateral sclerosis (ALS) [6] and primary lateral sclerosis (PLS) [7] and lower motor neuron predominant conditions are under evaluated [8-10]. Existing studies of lower motor neuron conditions typically solely evaluate spinal cord changes and cerebral changes are less well characterised [11, 12]. MNDs are also primarily associated with neurodegenerative change[5], decreased grey matter volume [13], cortical thinning [14], thalamus degeneration [15], fractional anisotropy reductions [16], and network dysfunction [17] despite emerging evidence of compensatory changes [18,19].

In this dataset, raw grey and white matter profiles of the study groups are presented in Fig. 1 and Fig. 2 as box plots. Additionally, demographically adjusted estimated marginal means are presented for key grey and white matter variables in Figs. 3 and 4. The comparative profile of study groups with reference to healthy individuals are illustrated by radar plots to further highlight regional grey (Fig. 5) and white matter alterations. (Fig. 6) Percentage change in grey matter partial volumes are calculated based on the estimated marginal means corrected for age, gender,

|                                         | Temporal lobe                                           |
|                                         | Thalamus                                                |

and lower-motor neuron disease (UMN/LMN), and healthy controls (HC). Patients underwent standardised clinical assessments and imaging with a uniform MR protocol on the same day. The imaging protocol implemented included T1-weighted, diffusion tensor imaging (DTI) and Fluid-attenuated inversion recovery (FLAIR) pulse sequences. T1-weighted images were acquired using a 3D Inversion Recovery prepared Spoiled Gradient Recalled echo (IR-SPGR) sequence with a spatial resolution of $1 \times 1 \times 1$ mm and field of view of $256 \times 256 \times 160$ mm; repetition time (TR) = 8.5 ms, echo time (TE) = 3.9 ms, Inversion time (TI) = 1060 ms, flip angle = 8°, SENSE factor = 1.5. DTI were acquired using a 32-direction SE-EPI sequence with field of view: $245 \times 245 \times 150$ mm, spatial resolution of 2.5 mm$^3$, 60 slices, repetition time / Echo time of 7639/59 ms. FLAIR images were acquired to assess for vascular white matter lesion load and images were individually reviewed by the same experienced neurologist. Total intracranial volumes (TIV) were estimated for each participant to be used as covariates for volumetric statistics. An atlas-based approach was implemented to define regions-of-interest (ROIs) and retrieve MR metrics from pre-defined anatomical regions [20,21]. FMRIB’s software library (FSL) v6.0 was used to process diffusion data. A tensor model was fitted to raw DTI data to generate maps of fractional anisotropy (FA), axial diffusivity (AD) and radial diffusivity (RD). Multivariate analyses of covariance (MANCOVA) were performed to explore intergroup differences adjusting for age,
gender and education for white matter metrics and also using TIV to compare partial volume profiles Table 1.
