Abstract

We calculate the $\mathcal{O}(\alpha_{\text{ew}})$ electroweak radiative corrections to $e^+e^- \rightarrow t\bar{t}h$ at a electron-positron linear collider (LC) in the standard model. We analyze the dependence of the $\mathcal{O}(\alpha_{\text{ew}})$ corrections on the Higgs boson mass $m_h$ and colliding energy $\sqrt{s}$, and find that the corrections significantly decrease or increase the Born cross section depending on the colliding energy. The numerical results show that the $\mathcal{O}(\alpha_{\text{ew}})$ relative correction is strongly related to the Higgs boson mass when $\sqrt{s} = 500$ GeV, and for $m_h = 150$ GeV the relative correction ranges from $-31.3\%$ to $2.3\%$ as the increment of the colliding energy from 500 GeV to 2 TeV.

I Introduction

The main goal of the most experimental programs at present and future high-energy colliders is to search for Higgs boson, which is believed to be responsible for the breaking of the electroweak symmetry and the generation of masses for the fundamental particles in the standard model (SM) \[1, 2\]. The fundamental particles acquire masses via the interactions with the ground state Higgs field in the SM Higgs mechanism. However, until now the Higgs boson hasn’t yet been directly explored experimentally, except that LEP2 experiments provided a lower bound of 114.4 GeV for the SM Higgs boson mass at the 95% confidence level \[3\].

As we know that the Higgs search strategies depend largely on the suspected value of Higgs mass. Actually, it is most difficult to probe Higgs boson experimentally in the intermediate mass region \((m_h \sim 100 – 200 \text{ GeV})\). In this mass region, the production mechanism with Higgs boson radiated from either a gauge boson or a fermion, is an important Higgs boson discovery channel. At \(e^+e^-\) linear colliders and hadron colliders, the Higgs boson is searched via Bjorken process \(e^+e^-(p\bar{p}, pp) \rightarrow f\bar{f}h\), an intermediate Higgs boson is produced associated with a \(f\bar{f}\) pair. The coupling strength of the fermion-Higgs Yukawa coupling \(f – \bar{f} – h\) is proportional to the fermion mass, i.e., \(g_{ffh} = m_f/v\), where \(v = (\sqrt{2}G_F)^{-1/2} \simeq 246 \text{ GeV}\) is the vacuum expectation value of the Higgs boson. Then we can see that the top quark Yukawa coupling \(g_{tth}\) is the largest one among all the fermion-Higgs couplings, e.g., \(g_{tth}^{2} \simeq 0.5\) to be compared for example with \(g_{bbh}^{2} \simeq 4 \times 10^{-4}\). Therefore, the Higgs boson production via the process \(e^+e^- \rightarrow t\bar{t}h\) is strongly enhanced by the top quark Yukawa coupling, and it can also be a basic mechanism for measuring the top quark Yukawa coupling.
Recently, a lot of efforts have been invested in improving the precise QCD theoretical corrections to the processes $p\bar{p}/pp \to t\bar{t}h + X$ [4, 5, 6, 7, 8]. At a LC the cross section for $e^+e^- \to t\bar{t}h$ is small, about 1 fb for $\sqrt{s} = 500$ GeV and $m_h = 100$ GeV [9, 10, 11]. But it has a distinctive experimental signature and can potentially be used to measure the top quark Yukawa coupling in the intermediate Higgs mass region at a LC with very high luminosity. In Ref. [10], S. Dawson and L. Reina found that the NLO QCD corrections increase the Born cross section by a factor of roughly 1.5 for $e^+e^- \to t\bar{t}h$ at $\sqrt{s} = 500$ GeV and $m_h = 100$ GeV. But at $\sqrt{s} = 1$ TeV, the corrections decrease the Born cross section and are relative small. These works show that the evaluation of radiative corrections is a crucial task for all accurate measurements of this process.

In this paper we present the calculations of the full $\mathcal{O}(\alpha_{ew})$ electroweak corrections to $e^+e^- \to t\bar{t}h$ in the SM. In section 2, we present our calculations of the full $\mathcal{O}(\alpha_{ew})$ electroweak radiative corrections. The numerical results and discussions are presented in section 3. Finally, a short summary is given.

II Calculations

In this paper we use the t’Hooft-Feynman gauge. In the calculations of loop diagrams we adopt the definitions of one-loop integral functions of Ref. [15]. The Feynman diagrams and the relevant amplitudes are created by *FeynArts* 3 [16] automatically, and the Feynman amplitudes are subsequently reduced by *FORM* [17]. The numerical calculations of integral functions are implemented by using Fortran programs, in which the 5-point loop integrals are evaluated by using the approach presented in Ref. [13].

The process $e^+e^- \to t\bar{t}h$ at the lowest level occurs through the Feynman diagrams of Fig.1. There
are two kinds of Feynman diagrams to the $e^+e^- \rightarrow t\bar{t}h$ process at the tree-level. The first kind includes diagrams with Higgsstrahlungs from top or anti-top final states and the top Yukawa coupling is thus involved. The second kind consists of the diagrams with a Higgs boson radiated from a $Z^0$-exchange s-channel or via $Z^0-G^0-h$-interaction, and is independent of the top Yukawa coupling. We have checked that our numerical Born cross section is in good agreement with that in Ref. [10, 12, 14].

The $\mathcal{O}(\alpha_{\text{ew}})$ (one-loop level) virtual corrections to the process

$$e^+(p_1) + e^-(p_2) \rightarrow t(k_1) + \bar{t}(k_2) + h(k_3)$$

(2.1)

can be expressed as

$$\sigma_{\text{virtual}} = \sigma_0 \delta_{\text{virtual}} = \frac{N_c}{2|k_1|\sqrt{s}} \int d\Phi_3 \sum_{\text{spin}} \text{Re} (\mathcal{M}_0 \mathcal{M}^*_\text{virtual}) ,$$

(2.2)

where $\sigma_0$ and $\mathcal{M}_0$ are the Born cross section and amplitude for $e^+e^- \rightarrow t\bar{t}h$, respectively, $d\Phi_3$ is the three-body phase space element, the bar over summation recalls averaging over initial spins, and $\mathcal{M}_{\text{virtual}}$ is the amplitude of one-loop Feynman diagrams and the corresponding counter-terms. Due to the fact that the electron-Higgs(Goldstone) Yukawa coupling is proportional to the electron mass, we do not consider the contributions of the one-loop diagrams which involve $\bar{e} - e - h(G^0)$ vertex to
the amplitude $\mathcal{M}_{\text{virtual}}$. Therefore, the $\mathcal{O}(\alpha_{\text{ew}})$ virtual corrections involve 975 loop diagrams which can be classified into self-energy (376), vertex (425), box (145) and pentagon (29) diagrams. As a representative selection, the pentagon diagrams are given in Fig.2.

The self-energy and vertex one-loop diagrams contain both ultraviolet (UV) and infrared (IR) divergences, while all the box and pentagon diagrams are ultraviolet finite and only contain IR divergences. To regularize the UV divergences in loop integrals, we adopt the dimensional regularization scheme \[18\] in which the dimensions of spinor and spacetime manifolds are extended to $D = 4 - 2\epsilon$. In this paper, we adopt the complete on-mass-shell (COMS) renormalization scheme \[19\], in which the electric charge of electron $e$ and the physical masses $m_W, m_Z, m_h, m_t, m_e$ are chosen to be the renormalized parameters. The definitions and the explicit expressions of these renormalization constants can be found in Ref. \[19\]. As we expect, the UV divergence contributed by the one-loop diagrams can be cancelled by that contributed by the counterterms exactly. Therefore, we get a UV finite cross section including $\mathcal{O}(\alpha_{\text{ew}})$ virtual radiative corrections.

The IR divergence in the process $e^+e^- \rightarrow t\bar{t}h$ is originated from virtual photonic corrections. It can be exactly cancelled by including the real photonic bremsstrahlung corrections to this process in the soft photon limit. The real photon emission process

$$e^+(p_1) + e^-(p_2) \rightarrow t(k_1) + \bar{t}(k_2) + h(k_3) + \gamma(k), \tag{2.3}$$

where the real photon radiates from the initial electron(positron) and the final top(anti-top) quark, can have either soft or collinear nature. The collinear singularity is regularized by keeping electron mass. In order to isolate the soft photon emission singularity in the real photon emission process, we use the general phase-space-slicing method \[20\]. The bremsstrahlung phase space is divided into
Figure 2 The pentagon diagrams for the $e^+e^- \rightarrow t\bar{t}h$ process.
singular and non-singular regions, and the cross section of the real photon emission process \( \sigma_{\text{real}} \) is decomposed into soft and hard terms

\[
\sigma_{\text{real}} = \sigma_{\text{soft}} + \sigma_{\text{hard}} = \sigma_0 (\delta_{\text{soft}} + \delta_{\text{hard}}).
\] (2.4)

For soft photons, \( k_0 < \Delta E \), we neglect the momenta of the radiated photons everywhere but in the singular propagators. By using the soft photon approximation, we find the contribution of the soft photon emission process is \([19, 21]\)

\[
d\sigma_{\text{soft}} = -d\sigma_0 \frac{\alpha_{\text{ew}}}{2\pi^2} \int_{|k| \leq \Delta E} \frac{d^3k}{2k_0} \left[ \frac{Q_e p_1}{p_1 \cdot k} - \frac{Q_e p_2}{p_2 \cdot k} - \frac{Q_t k_1}{k_1 \cdot k} + \frac{Q_t k_2}{k_2 \cdot k} \right]^2,
\] (2.5)
in which \( \Delta E \) is the energy cutoff of the soft photon and \( k_0 \leq \Delta E \ll \sqrt{s} \), \( Q_e = 1 \) and \( Q_t = 2/3 \) are the electric charges of the positron and top quark. \( k_0 = \sqrt{|\vec{k}|^2 + \mu^2} \) is the photon energy. The integral over the soft photon phase space have been implemented, therefore, we obtain the analytical result of the soft corrections to \( e^+e^- \to t\bar{t}h \) which can be found in Refs. \([19]\) and \([21]\). We checked numerically the cancellation of IR divergencies and verified the contribution of these soft photonic bremsstrahlung corrections leads to a IR finite cross section which is independent of the infinitesimal photon mass \( \mu \).

The hard photon emission cross section \( \sigma_{\text{hard}} \), with the radiated photon energy being larger than \( \Delta E \), is calculated by using Monte Carlo method.

Finally the UV and IR finite total cross section including the full \( O(\alpha_{\text{ew}}) \) electroweak corrections reads

\[
\sigma = \sigma_0 + \Delta \sigma = \sigma_0 + \sigma_{\text{virtual}} + \sigma_{\text{real}} = \sigma_0 (1 + \delta),
\] (2.6)

where \( \delta = \delta_{\text{virtual}} + \delta_{\text{soft}} + \delta_{\text{hard}} \) is the full electroweak relative correction of the order \( O(\alpha_{\text{ew}}) \).
III Numerical results and discussions

In our numerical calculations, we set \( \alpha_{\text{ew}}(0)^{-1} = 137.0359895 \), \( m_W = 80.423 \) GeV, \( m_Z = 91.188 \) GeV, \( m_e = 0.511 \) MeV, \( m_\mu = 105.7 \) MeV, \( m_\tau = 1.777 \) GeV, \( m_u = 66 \) MeV, \( m_c = 1.35 \) GeV, \( m_t = 174.3 \) GeV, \( m_d = 66 \) MeV, \( m_s = 150 \) MeV, and \( m_b = 4.3 \) GeV. The renormalization scale is taken to be \( Q = 2m_t + m_h \). Here we use the effective values of the light quark masses \((m_u\text{ and }m_d)\) which can reproduce the hadron contribution to the shift in the fine structure constant \( \alpha_{\text{ew}}(m_Z) \) \( \text{[23]} \).

Figure 3 The relative corrections of the \( \mathcal{O}(\alpha_{\text{ew}}) \) order contributions to the \( e^+e^-\to t\bar{t}h \) cross section. The relative corrections of \( \delta_{\text{virtual+soft}} \) and \( \delta_{\text{hard}} \), and their sum are shown as the functions of the soft photon energy cutoff \( \Delta E/E_h \).
In Fig. 3 we show the dependence of the \( \mathcal{O}(\alpha_{\text{ew}}) \) relative correction to \( e^+e^- \rightarrow t\bar{t}h \) on the soft cutoff \( \Delta E/E_b \), assuming \( m_h = 115 \text{ GeV} \) and \( \sqrt{s} = 500 \text{ GeV} \). As shown in this figure, both \( \delta_{\text{virtual+soft}} (= \delta_{\text{virtual}} + \delta_{\text{soft}}) \) and \( \delta_{\text{hard}} \) depend on the soft cutoff \( \Delta E/E_b \), but the full \( \mathcal{O}(\alpha_{\text{ew}}) \) electroweak relative correction \( \delta \) is cutoff independent within the range of statistical errors as expected. In the following calculations, the soft cutoff \( \Delta E/E_b \) is fixed to be \( 10^{-3} \).

Figure 4 The Born and one-loop level cross sections for the process \( e^+e^- \rightarrow t\bar{t}h \) as functions of the \( e^+e^- \) colliding energy \( \sqrt{s} \).

In Fig. 4 we present the Born cross section \( \sigma_0 \) and the one-loop level cross section \( \sigma \) which include the full \( \mathcal{O}(\alpha_{\text{ew}}) \) electroweak corrections, as functions of the \( e^+e^- \) colliding energy \( \sqrt{s} \) for the Higgs boson.
mass $m_h = 115$ GeV, 150 GeV and 200 GeV, respectively. The colliding energy range (500 GeV $\sim$ 2 TeV) in the figure is accessible at future linear colliders, such as, TESLA [24] ($\sqrt{s} = 500$ GeV), NLC [25] ($\sqrt{s} = 500$ GeV), JLC [26] ($\sqrt{s} = 500$ GeV,) and CERN CLIC [27] (1 TeV $< \sqrt{s} < 5$ TeV). From this figure we can see that both curves of $\sigma_0$ and $\sigma$ for $m_h = 115$ GeV reach maximal values at the position of $\sqrt{s} \sim 750$ GeV, where the correction $\Delta\sigma$ can reach 0.09 fb. For $m_h = 150$ GeV and 200 GeV, both $\sigma_0$ and $\sigma$ have their maximal values at $\sqrt{s} \sim 850$ GeV and $\sqrt{s} \sim 950$ GeV, respectively. The correction $\Delta\sigma$ decreases as the increment of the Higgs boson mass $m_h$.

Figure 5 The dependence of the $\mathcal{O}(\alpha_{\text{ew}})$ relative correction to $e^+e^- \rightarrow t\bar{t}h$ on the $e^+e^-$ colliding energy $\sqrt{s}$. 

10
The dependence of the $\mathcal{O}(\alpha_{\text{ew}})$ relative correction to $e^+e^- \to t\bar{t}h$ on the colliding energy $\sqrt{s}$ of a LC is displayed in Fig.5. For $m_h = 115$ GeV, the $\mathcal{O}(\alpha_{\text{ew}})$ corrections suppress the Born cross section in the energy region of $\sqrt{s} < 600$ GeV, while enhance the Born cross section in the region of $\sqrt{s} > 600$ GeV. The relative corrections can reach about $-5.8\%$, $-31.3\%$ and $-8.3\%$ at $\sqrt{s} = 500$, 500 and 600 GeV for $m_h = 115$, 150 and 200 GeV, respectively. For $m_h = 150$ GeV, the relative correction ranges from $-31.3\%$ to $2.3\%$ as $\sqrt{s}$ running from 500 GeV to 2 TeV. The large correction for $\sqrt{s} = 500$ GeV and $m_h \sim 150$ GeV shown in this figure comes from a threshold effect which diverges at the threshold.

**Figure 6** The Born and one-loop level cross sections for the process $e^+e^- \to t\bar{t}h$ as functions of the Higgs boson mass $m_h$.  

11
In Fig. 6 we depict the Born cross section $\sigma_0$ and the one-loop level cross section $\sigma$ as functions of the Higgs boson mass $m_h$. As shown in this figure, both the cross sections $\sigma_0$ and $\sigma$ decrease with the increment of the Higgs boson mass, and the cross sections $\sigma_0$, $\sigma$ and the one-loop level correction $\Delta\sigma = \sigma - \sigma_0$ at $\sqrt{s} = 800$ GeV are larger than those at $\sqrt{s} = 500$ GeV and $\sqrt{s} = 2$ TeV.

**Figure 7** The $O(\alpha_{em})$ relative correction to the process $e^+e^- \rightarrow t\bar{t}h$ as a function of the Higgs boson mass $m_h$.

In Fig. 7 we plot the $O(\alpha_{em})$ relative correction $\delta$ to $e^+e^- \rightarrow t\bar{t}h$ as a function of $m_h$. For $\sqrt{s} = 500$ GeV, the relative correction decreases from $-5.8\%$ at $m_h = 115$ GeV to $-31.3\%$ at $m_h = 150$ GeV. For $\sqrt{s} = 800$ GeV and 2 TeV, the relative corrections decrease from 4.4\% and 1.5\% to $-0.8\%$ and
−4.7% as the increment of $m_h$ from 115 GeV to 200 GeV, respectively. The $\mathcal{O}(\alpha_{\text{ew}})$ electroweak relative corrections are not very sensitive to the Higgs boson mass in the range of $115 \text{ GeV} < m_h < 200 \text{ GeV}$ when $\sqrt{s} = 800 \text{ GeV}$ and 2 TeV, but strongly depend on the Higgs boson mass when $\sqrt{s} = 500 \text{ GeV}$. In both Fig.6 and Fig.7, we can see that each of the two curves of the total cross sections including the $\mathcal{O}(\alpha_{\text{ew}})$ corrections at $\sqrt{s} = 800 \text{ GeV}$ and 2 TeV, has two spikes at the vicinities of $m_h = 2m_W$ and $m_h = 2m_Z$, due to the threshold effects.

After submitting this manuscript, we acknowledged another two papers appeared on this subject [28, 29]. The representative comparison with the calculation of Ref.[29] is shown in Table 2 of [29](There we use the current mass values for $m_u$ and $m_d$). It shows that most of our numerical results of one-loop electroweak corrected cross sections agree with theirs within estimated error, but there are some discrepancies at the energy $\sqrt{s} = 2 \text{ TeV}$.

IV Summary

In this paper we calculate the full electroweak one-loop level radiative corrections to the process $e^+e^- \rightarrow t\bar{t}h$ at an electron-positron LC in the standard model. We analyze the dependence of the electroweak radiative corrections on the Higgs boson mass $m_h$ and colliding energy $\sqrt{s}$, and find that the corrections increase or decrease the Born cross section in the Higgs boson mass range $115 \text{ GeV} < m_h < 200 \text{ GeV}$, depending on the colliding energy. The numerical results show that the $\mathcal{O}(\alpha_{\text{ew}})$ electroweak relative corrections can reach $-31.3\%$, $4.4\%$ and $-4.7\%$ at $\sqrt{s} = 500 \text{ GeV}$, 800 GeV and 2 TeV, respectively. We also find that the full electroweak relative correction of the order $\mathcal{O}(\alpha_{\text{ew}})$ is strongly related to the Higgs boson mass when $\sqrt{s} = 500 \text{ GeV}$, and for $m_h = 150 \text{ GeV}$ the relative
correction ranges from $-31.3\%$ to $2.3\%$ as the colliding energy increasing from 500 GeV to 2 TeV.
