Abstract Using solid-state reactions method the ceramic samples of Na$_{0.89}$Co$_{0.9}$M$_{0.1}$O$_2$ (M = Sc, Ti, Cr–Zn, Mo, W, Pb, Bi) solid solutions had been prepared, their lattice constants had been determined and their microstructure, thermal expansion, thermal conductivity, electrical conductivity and thermo-EMF had been measured, and their power factor and figure-of-merit values had been calculated. Effect of the cobalt substitution by other metals in the Na$_{0.89}$Co$_{0.9}$O$_2$ on the crystal structure and physicochemical and functional properties of its derivatives was analyzed. It was found that Na$_{0.89}$Co$_{0.9}$M$_{0.1}$O$_2$ cobaltates are the p-type conductors, which linear thermal expansion coefficient (LTEC) values varied within (1.24–2.05)·10$^{-5}$ K$^{-1}$. It was found that the best thermoelectric properties among the oxides studied possessed Na$_{0.89}$Co$_{0.9}$Ni$_{0.1}$O$_2$ and Na$_{0.89}$Co$_{0.9}$Bi$_{0.1}$O$_2$ solid solutions which power factor and figure-of-merit estimated values at 1100 K are equal to 0.919 and 0.660 mW/(m·K) and 1.12 and 0.83 respectively.

Keywords Layered Sodium Cobaltate, Thermoelectrics, Thermal Expansion, Thermal Conductivity, Electrical Conductivity, Thermo-EMF, Power Factor, Figure-of-Merit

1. Introduction

Heat which is released into environment during working of industrial factories and transport, can be effectively and directly converted into electrical energy using thermoelectric generators (TEG). To create TEG it is need to use so-called thermoelectrics – materials possessing high values of electrical conductivity, thermal conductivity and thermo-EMF coefficient and low values of thermal conductivity [1]. Such set of properties have bismuth (Bi$_2$Te$_3$) and antimony tellurides (Sb$_2$Te$_3$) and their solid solutions, skutterudites (for example, Yb$_2$Co$_4$Sb$_{12–x}$Sb$_x$ [2]), as well as silicides of iron and other metals (FeSi$_2$, Mg(Si,Ge)$_2$) [1, 3], which are used as materials for TEG and thermoelectric cooling batteries (TCB) since second half of the last century.

Classical thermoelectrics based on tellurides of heavy metals are characterized by high cost, high toxicity of the some components, and low stability at elevated temperatures in air, including possibility of their partial oxidation by atmospheric oxygen. The latter limits the usage of these materials at high temperature thermoelectric conversion.

Oxide thermoelectrics deprived of this deficiency [4], and their active investigation began after discovery of high thermoelectric efficiency in NaCo$_2$O$_4$ single crystals by Terasaki et al. in 1987 [5].

Layered sodium cobaltate Na$_x$Co$_{2}$O$_4$ is characterized by high values of electrical conductivity and thermo-EMF and low thermal conductivity [4–6], which allows us to consider it as prospective base for development of the new effective oxide thermoelectrics. To improve the functional (thermoelectric) parameters of materials based on it one can using solution methods of the synthesis [7, 8], spark plasma sintering [9] as well as by means of partial substitution of sodium ions [10] or cobalt ions in its structure by other metal ions [11–16].

Partial substitution of cobalt by copper in the Na$_{0.5}$Co$_{1–x}$Cu$_x$O$_2$ ceramics improves its sinterability and increases its electrical conductivity ($\sigma$) and thermo-EMF coefficient ($S$) whereupon power factor ($P$) values of the solid solutions rise in contrast to the unsubstituted phase reaching the maximal value for Na$_{0.5}$Co$_{0.9}$Cu$_{0.1}$O$_2$ – 3.08 mW/(m·K$^2$) at 1073 K temperature [11]. Substitution of cobalt by nickel deteriorates the sinterability and decreases electrical conductivity of Na$_{0.5}$Co$_{1–x}$Ni$_x$O$_2$ phases but leads to the increasing of their thermo-EMF coefficient, at that the $P$ value for Na$_{0.5}$Co$_{0.9}$Ni$_{0.1}$O$_2$ solid solution at 1073 K is equal to 2.36 mW/(m·K$^2$) which is 8 times higher than for bases oxide Na$_{0.5}$Co$_{2}$O$_4$ [12]. Partial substitution of cobalt by zinc in Na$_{0.5}$Co$_{1–x}$Zn$_x$O$_2$ leads to the increasing of the $\sigma$ and $S$ values of ceramics and power factor value of Na$_{0.5}$Co$_{0.95}$Zn$_{0.05}$O$_2$ solid solution reaches 1.7 mW/(m·K$^2$) at 1073 K, which is 4 times higher than for unsubstituted sodium cobaltate Na$_{x}$Co$_{2}$O$_4$ [13].

In the works of [14, 15] at attempt of improving of thermoelectric properties of Na$_4$Co$_2$O$_4$ ceramics by means of
substitution of cobalt by silver it was established that solubility of Ag2O in Na2CO3 is small, that is why the Na0.85Co0.9Ag0.1O2 samples are microcomposites, which matrix is Na0.85Co0.9Ag0.1O2 solid solution, but silver is allocated at the grain boundaries as Ag or Ag2O [15, 16]; functional characteristics of these composites are better than for basis oxide Na2CoO2: figure-of-merit (ZT) of ceramics at 973 K is equal to 0.04 and 0.12 for Na0.75CoO2 and Na0.5CoO2·Ag2O1.2O2 respectively [15], but power factor reaches the value of 0.687 mW/(m·K2) for the sample with composition of Na0.85Co0.9Ag0.1O2 [16].

It is known, that increasing of sodium content in the Na2CoO2 phases increases their power factor and figure-of-merit values [17, 18]. Further, analysis of the literature data shows that optimal substitution level of cobalt ions by other metal ions in Na2CoO2 is 5–10 mol.% but problem of the search of optimal substituents is still not solved.

To take part in the solving of such problem in this work the influence of the nature of different metal ions on the crystal structure, microstructure, physicochemical and functional (thermoelectric) properties of the Na0.89Co0.9Ag0.1O2 solid solutions was investigated.

2. Materials and Methods

The ceramic samples of the cobaltates with composition of Na0.9Co0.9M0.1O2 (M = Sc, Ti, Cr–Zn, Mo, W, Pb, Bi) were obtained using solid-state reactions method from Na2CO3 (pure for analysis grade), Sc2O3 (super pure grade), TiO2 (pure for analysis grade), Cr2O3 (pure for analysis grade), Mn2O3 (super pure grade), Fe2O3 (super pure grade), Co3O4 (pure grade), NiO (super pure grade), CuO (pure for analysis grade), ZnO (pure grade), MoO3 (pure grade), WO3 (pure grade), PbO (pure for analysis grade), and Bi2O3 (pure grade), which were taken in relation of Na : Co : M = 1.2 : 0.9 : 0.1 (excess of Na2CO3 in the initial mixture compensates the losses of Na2O by the samples during their thermal treatment and allow us to obtain the ceramics of the predetermined composition [19]) in air within 1183–1233 K temperature interval.

Identification of the samples and determination of their lattice constants was performed using X-ray diffraction analysis (XRD) (Bruker D8 XRD Advance diffractometer, CuKα-radiation, Ni filter). On the base of XRD results the X-ray density of the samples (ρXRD) values were calculated. IR-absorption spectra of the powder samples were recorded in the tablet mixtures with KBr (chemically pure grade) for the Nexus ThermoNicolet Fourier spectrometer in the frequency range 300–1500 cm−1. Microstructure of the sintered ceramics was studied using scanning electron microscope JSM–5610 LV. The apparent density (ρ) of the samples was calculated using their mass and geometrical dimensions and porosity (Π) of the sintered ceramics was found using formula Π = (1–ρ/ρXRD)-100% [20].

Thermal expansion, electrical conductivity and thermo-EMF coefficient of the samples were investigated in air within 300–1100 K temperature interval by methods described in [19, 21, 22]. Linear thermal expansion coefficient (LTEC, α) values of the oxides studied were calculated from the linear parts of the Δl/l0 = f(T) dependences. Values of power factor and figure-of-merit of the ceramics were calculated using formulae P = S2σ; ZT = (P/T)λ, where λ is thermal conductivity of ceramics, T is the absolute temperature [4, 23]. Thermal conductivity of the samples was measured within 298–423 K temperature interval by means of thermal conductivity meter IT–λ–400. Lattice (phonon) (λph) and electronic (λel) parts of thermal conductivity were found using relations of λ = λph + λel, λel = σ·L·T, where L is the Lorentz number(L=2.45·10−8 W·Ω·K−2) [23].

3. Results and Discussion

After final stage of the synthesis all the Na0.89Co0.9M0.1O2 solid solutions were, within XRD accuracy, monophase (Figure 1, lines 1–5), although on the IR absorption spectra of powders besides the absorption band of the main phase (layered sodium cobaltate) the bands of impurity phases (Na2CO3 and Co3O4) were observed (Figure 1, lines 6–10), which are formed by partial degradation of the surface of powder particles due to their interaction with atmospheric carbon dioxide. Values of absorption extrema of the IR absorption spectra of the Na0.89Co0.9Ag0.1O2 solid solutions was equal to 3.85–3.88, which is also close to the characteristics of the base sodium cobaltate (for Na0.89Co2O4 c/a = 3.87) (Table 1). So, partial substitution of cobalt by other metals in Na0.89Co2O4 do not lead to the essential changes of the size and form of the unit cell of solid solutions formed at this substitution in comparison to the unsubstituted phase.

On the IR absorption spectra of the Na0.89Co0.9M0.1O2 powders the absorption bands with extrema at 561–575 cm−1 were observed (Figure 1, lines 6–10), which correspond to the vibrations of (Co,M)–O bonds in the −[(Co,M)O2]− layers of their crystal structure [25] as well as the absorption bands of Na2CO3 and Co3O4 impurity phases, which are formed, as it was mentioned above, due to the partial degradation of the surface of the powders particles due to their interaction with atmospheric carbon dioxide. Values of absorption extrema of the samples studied were close each other; so, partial substitution of cobalt by other metals in Na0.89Co2O4 do not changed practically the energy of metal–oxygen interactions
in its structure. It should be noted that IR-absorption spectroscopy results are in a good accordance with the XRD data which show that lattice constants of \( \text{Na}_0.89\text{Co}_{0.9}M_{0.1}\text{O}_2 \) solid solutions are close to the lattice constants of unsubstituted sodium cobaltate \( \text{Na}_0.89\text{CoO}_2 \).

Values of X-ray density of the samples varied within 4.80–5.56 g/cm\(^3\) and increased regularly at partial substitution of cobalt by heavy metals (Mo, W, Pb, Bi) (Table 1).

The sizes of crystallites (values of coherent scattering area) \( t \) of the samples, which was determined using the Debye–Sherrer equation

\[
t = \frac{(0.9\lambda)}{(\beta \cos \Theta)}
\]

where \( \lambda \) is wavelength, \( \beta \) is width of reflex on its half of height, and \( \Theta \) is the diffraction angle [26], are given in the Table 1. As can be seen, values of crystallites for \( \text{Na}_0.89\text{Co}_{0.9}M_{0.1}\text{O}_2 \) solid solution are equal to 59–82 nm and are larger than for base sodium cobaltate (50 nm) (Table 1), and the maximal value of coherent scattering area possesses \( \text{Na}_0.89\text{Co}_{0.9}\text{Cu}_{0.1}\text{O}_2 \) solid solution (82 nm).

**Table 1.** Lattice constants \( (a, c, c/a, V) \), x-ray \( (\rho_{XRD}) \) and apparent \( (\rho) \) density as well as coherent scattering area \( (t) \) of the \( \text{Na}_0.89\text{Co}_{0.9}M_{0.1}\text{O}_2 \) solid solutions

Figure 2. Electron micrographs of Na\(_{0.89}\)Co\(_{0.9}\)M\(_{0.1}\)O\(_2\) ceramic cleavages: \(M = \) Sc (A), Ti (B), Cr (C), Mn (D), Fe (E), Co (F), Ni (G), Cu (H), and Zn (I).

Apparent density of the sintered ceramics varied within 4.80–5.56 g/cm\(^3\) (Table 1) decreasing at substitution of cobalt by other 3\(d\)-metals (Sc, Ti, Cr–Zn) and increasing at substitution of cobalt by 4\(d\)- (Mo), 5\(d\)- (W) and 6\(p\)-metals (Pb, Bi). Values of porosity of the Na\(_{0.89}\)Co\(_{0.9}\)M\(_{0.1}\)O\(_2\) samples (29–42\%) were less than for Na\(_{0.89}\)CoO\(_2\) (28\%) (Table 2), which implies that partial substitution of cobalt by other metals in Na\(_{0.89}\)CoO\(_2\) deteriorates sinterability of its derivatives.

As can be seen from the Figure 2, the grains of Na\(_{0.89}\)Co\(_{0.9}\)M\(_{0.1}\)O\(_2\) ceramics were anisometric and plate-like with thickness of 1–10 \(\mu\)m and width of 8–50 \(\mu\)m. The form of the grains was close to hexagonal which is characteristic for hexagonal sodium cobaltate. According to
the XRD results, the crystallites sizes of Na_{0.89}Co_{0.9}M_{0.1}O_2 cobaltates varied within 50–82 nm (Table 1); so, the grains of the ceramics were polycrystalline and contained more than million crystallites. It is interesting to note that habitus and grain size of the ceramics significantly changed when the nature of 3d-metals substituting cobalt in Na_{0.89}CoO_2 changed. For example, the Na_{0.89}Co_{0.9}Mn_{0.1}O_2 ceramic grains had the smallest size and shape of thin plates (Figure 2, D), whereas Na_{0.89}Co_{0.9}M_{0.1}O_2 (M = Ti, Cr, Cu) ceramics consisted of relatively large grains having shape of the thick plates (Figure 2, B, C, H). Thus, the microstructure of ceramics based on the layered sodium cobaltate can be effectively controlled by addition different transition metal oxides to the samples.

Temperature dependences of the relative elongation of Na_{0.89}Co_{0.9}M_{0.1}O_2 ceramic samples were linear practically; so, we can conclude that within temperature interval studied these compounds do not undergo any structural phase transitions. LTEC values of the Na_{0.89}Co_{0.9}M_{0.1}O_2 solid solutions varied within (1.24–2.05)·10^{-5} K^{-1} and, excluding Na_{0.89}Co_{0.9}Cu_{0.1}O_2, Na_{0.89}Co_{0.9}Pb_{0.1}O_2 and Na_{0.89}Co_{0.9}Bi_{0.1}O_2 cobaltates, were larger than for unsubstituted sodium cobaltate Na_{0.89}CoO_2 (1.34·10^{-5} K^{-1}) (Table 2).

Obtained increasing of LTEC values of Na_{0.89}Co_{0.9}M_{0.1}O_2 derivatives in comparison to the Na_{0.89}CoO_2 base phase, by our opinion, is due to the high values of their porosity (Table 2) as well as to the increasing of anharmonicity degree of metal–oxygen vibrations in their structure at partial substitution of cobalt by other metals.

As can be seen from the Figure 3, A, D, electrical conductivity of Na_{0.89}CoO_2 and its Na_{0.89}Co_{0.9}M_{0.1}O_2 derivatives has metallic character (\(\partial \sigma / \partial T < 0\)), which for Na_{0.89}Co_{0.9}Mo_{0.1}O_2, Na_{0.89}Co_{0.9}Pb_{0.1}O_2, and Na_{0.89}Co_{0.9}Bi_{0.1}O_2 solid solutions at high temperatures (\(T > 800–900\) K) changes to semiconducting (\(\partial \sigma / \partial T < 0\)) (excluding Na_{0.89}Co_{0.9}W_{0.1}O_2, which electrical conductivity within all the temperature interval studied has semiconducting character, and Na_{0.89}Co_{0.9}Fe_{0.1}O_2, which electrical conductivity value did not depend on the temperature practically).

![Figure 3](image)

**Figure 3.** Temperature dependences of electrical conductivity (\(\sigma\)) (A, D), thermo-EMF coefficient (\(S\)) (B, E), and power factor (\(P\)) (C, F) of Na_{0.89}Co_{0.9}M_{0.1}O_2 sintered ceramics: M = Sc (1), Cr (2), Mn (3), Fe (4), Co (5), Ni (6), Cu (7), Mo (8), W (9), Pb (10), and Bi (11). Insets: dependences of electrical conductivity (\(\sigma_{1100}\)) (G), thermo-EMF coefficient (\(S_{1100}\)) (H) on the number of electrons (n) on the external electron shell of metal cations substituting cobalt cations in Na_{0.89}CoO_2 phase.
Herewith, electrical conductivity values of the samples, in the whole, decreased at increasing oxidation degree of metals substituting cobalt in Na$_{0.89}$Co$_2$O$_2$ ($\sigma$(Na$_{0.89}$Co$_{0.9}$Cu$_{0.1}$O$_2$) > $\sigma$(Na$_{0.89}$Co$_{0.9}$Bi$_{0.1}$O$_2$) > $\sigma$(Na$_{0.89}$CoO$_2$)) (Figure 3, A, D, Table 2), which are in good agreement with the results of [11–13] and can be explained by decreasing of concentration of main charge carriers (“holes”) in the layered sodium cobaltate derivatives at increasing of average oxidation degree of cations in the conducting –[$(\text{Co}, M)$O$_2$]– layers of the crystal structure of Na$_{0.89}$Co$_{0.9}$M$_{0.1}$O$_2$ phases.

Values of thermo-EMF coefficient of the Na$_{0.89}$Co$_{0.9}$M$_{0.1}$O$_2$ increased at temperature increasing and, in the whole, at increasing of oxidation degree of metal substituting cobalt in Na$_{0.89}$Co$_2$O$_2$ (Figure 3, B, E, Table 2), which is typical for common conductors, for which increasing of concentration of main charge carriers leads to the increasing of electrical conductivity values and decreasing of their thermo-EMF coefficient. At the same time, $S$ values of Na$_{0.89}$Co$_{0.9}$Ni$_{0.1}$Co$_2$O$_2$, Na$_{0.89}$Co$_{0.9}$Cu$_{0.1}$O$_2$, Na$_{0.89}$Co$_{0.9}$W$_{0.1}$O$_2$, and Na$_{0.89}$Co$_{0.9}$Bi$_{0.1}$O$_2$ were abnormally larger than for Na$_{0.89}$Co$_2$O$_2$, which cannot be explained in the frame of quasi-chemical approach.

It is known, that electronic subsystem of layered sodium cobaltate Na$_x$CoO$_2$ and its derivatives is strongly correlated, and value of their thermo-EMF coefficient described using modified Heikes’s equation

$$ S = (k/e) \ln \left( \frac{g_4[\text{Co}^{3+}]}{g_3[\text{Co}^{4+}]} \right), $$

where $k$ is the Boltzmann’s constant, $e$ is charge of electron, $g_4$ and $g_3$ are degeneracy of Co$^{4+}$ and Co$^{3+}$ ions respectively, [Co$^{3+}$] and [Co$^{4+}$] are concentration’s of Co$^{3+}$ and Co$^{4+}$ ions in conducting –[CoO$_2$]– layers of Na$_x$CoO$_2$ crystal structure [27].

So, thermo-EMF coefficient of Na$_{0.89}$Co$_{0.9}$M$_{0.1}$CoO$_2$ is determined both ratio of concentrations of [Co$^{3+}$]/[Co$^{4+}$], which depends on oxidation degree of metals substituting cobalt in Na$_{0.89}$Co$_2$O$_2$, and ratio of degeneracy’s $g_4/g_3$, which depends on spin states of cobalt ions Co$^{3+}$, Co$^{4+}$ and metal-substituent $M^{+}$. As can be seen from the Figure 3, G, H, electrical conductivity Na$_{0.89}$Co$_{0.9}$M$_{0.1}$CoO$_2$ cobaltates increases, but thermo-EMF coefficient decreases at increasing of number of electrons on the external electron shell of metal cation $M^{+}$ substituting cobalt cations in Na$_{0.89}$Co$_2$O$_2$. So, we can conclude, that electrotransport properties of the Na$_{0.89}$Co$_{0.9}$M$_{0.1}$CoO$_2$ solid solutions are determined both charge and spin states of cations in the conducting –[CoO$_2$]– layers of their crystal structure.

This is in a good accordance with the conclusions, which had been done by authors of [27] at analysis of concentration dependence of thermo-EMF coefficient of Na$_x$CoO$_2$ cobaltates with varying sodium content.

Power factor values of Na$_{0.89}$Co$_{0.9}$M$_{0.1}$O$_2$ sintered ceramics increased at temperature increasing and nonmonotonously changed at changing of the nature of metal substituting cobalt in Na$_{0.89}$Co$_2$O$_2$ (Figure 3, C, F, Table 2), reaching the maximal values for Na$_{0.89}$Co$_{0.9}$Ni$_{0.1}$O$_2$, Na$_{0.89}$Co$_{0.9}$Cu$_{0.1}$O$_2$, and Na$_{0.89}$Co$_{0.9}$Cu$_{0.1}$O$_2$ solid solutions – 0.919, 0.660, and 0.615 mW/(m·K$^2$) respectively, which is 2.18, 1.57, and 1.46 times larger, than for unsubstituted layered sodium cobaltate Na$_{0.89}$Co$_2$O$_2$, and determined, mainly, by the high values of their thermo-EMF coefficient values.

As it seen from the data, which are given on the Figure 4, A, and in the Table 2, values of thermal conductivity of ceramics studied within 298–423 K temperature interval, were, in the whole, close to each other, and varied within 0.78–0.96 W/(m·K), and for the Na$_{0.89}$Co$_{0.9}$M$_{0.1}$O$_2$ solid solutions were larger (for Na$_{0.89}$Co$_{0.9}$Ni$_{0.1}$O$_2$ and Na$_{0.89}$Co$_{0.9}$Cu$_{0.1}$O$_2$ samples at $T < 310–320$ K less), than for unsubstituted sodium cobaltate Na$_{0.89}$Co$_2$O$_2$.

![Figure 4](image-url)

Figure 4. Temperature dependences of thermal conductivity ($\lambda$, W/(m·K)) (A) and figure-of-merit (ZT) (B) of Na$_{0.89}$Co$_{0.9}$M$_{0.1}$O$_2$ cobaltates: $M = \text{Co (1), Ni (2), Cu (3), Mo (4), and Bi (5)}$.
Value of thermal conductivity of Na$_{0.89}$Co$_{0.9}$M$_{0.1}$O$_2$ (M = Ni, Cu, Mo, Bi) solid solutions increased at temperature increasing (Figure 4, A). Electronic part of thermal conductivity of cobaltates studied was small ($\lambda_e/\lambda \approx 0.03–0.16$) and, in the whole, increased at temperature increasing. So, main part of heat transferred through the Na$_{0.89}$Co$_{0.9}$M$_{0.1}$O$_2$ phases by means of lattice vibrations (phonons) ($\lambda_m \approx (0.84–0.98)\lambda$).

Dimensionless figure-of-merit ($ZT$) of Na$_{0.89}$Co$_{0.9}$M$_{0.1}$O$_2$ cobaltates within 298–423 K temperature interval increased at increasing of temperature (Figure 4, B) and reached maximal values for Na$_{0.89}$Co$_{0.9}$Ni$_{0.1}$O$_2$, and Na$_{0.89}$Co$_{0.9}$Cu$_{0.1}$O$_2$ – 0.22, and 0.10 respectively at 423 K, when 4.4 and 2.0 times larger, than for Na$_{0.89}$Co$_{0.9}$ cobaltate (0.05) at the same temperature (Table 2). In the Table 2 are given also estimated values of $ZT_{1100}$ for Na$_{0.89}$Co$_{0.9}$Ni$_{0.1}$O$_2$ ceramics, calculated using equation $ZT_{1100} = (P^{1100})/\lambda_{1100}$ (taking into account the weak dependence of thermal conductivity of ceramics obtained in this work on the temperature). As it seen, the best thermoelectric performance at 1100 K are expected for Na$_{0.89}$Co$_{0.9}$Ni$_{0.1}$O$_2$ and Na$_{0.89}$Co$_{0.9}$Bi$_{0.1}$O$_2$ samples, which estimated values of $ZT_{1100}$ are equal to 1.12 and 0.83 respectively. That is 2.0 and 1.5 times larger, than for unsubstituted sodium cobaltate Na$_{0.89}$Co$_{0.9}$O$_2$ (0.56) and is close to the theoretical criteria ($ZT > 1$ [1]), determining materials, which are in interest for the practical thermoelectric conversion.

4. Conclusions

By means of the solid-state reactions method the Na$_{0.89}$Co$_{0.9}$M$_{0.1}$O$_2$ (M = Sc, Ti, Cr–Zn, Mo, W, Pb, Bi), cobaltates solid solutions were prepared, their crystal structure, microstructure, thermostophysical, electrophysical and thermoelectric (functional) properties were studied. It was found, that Na$_{0.89}$Co$_{0.9}$M$_{0.1}$O$_2$ cobaltates are p-type conductors, which LTEC values varied within (1.24–2.05)·10$^{-5}$K$^{-1}$. The influence of the nature of metal substituting cobalt in Na$_{10.89}$Co$_{0.9}$O$_2$ on the lattice constants, shape and size of the grains of Na$_{0.89}$Co$_{0.9}$M$_{0.1}$O$_2$ ceramics, values of its electrical conductivity and thermo-EMF was analyzed. It was shown, that doping of Na$_{0.89}$Co$_{0.9}$O$_2$ sodium cobaltate by other metal oxides let us improve thermoelectric parameters of the solid solutions forming at this doping. So, power factor of Na$_{0.89}$Co$_{0.9}$Ni$_{0.1}$O$_2$, Na$_{0.89}$Co$_{0.9}$Bi$_{0.1}$O$_2$, Na$_{0.89}$Co$_{0.9}$Cu$_{0.1}$O$_2$, and Na$_{0.89}$Co$_{0.9}$O$_2$ at 1100 K is equal to 0.919, 0.660, 0.615, and 0.421 mW/(m·K$^2$) respectively, dimensionless figure-of-merit of Na$_{0.89}$Co$_{0.9}$Ni$_{0.1}$O$_2$, Na$_{0.89}$Co$_{0.9}$Cu$_{0.1}$O$_2$ and Na$_{0.89}$Co$_{0.9}$O$_2$ at 423 K is equal to 0.056, 0.22, 0.10, and 0.05 respectively, and its estimated values at 1100 K for Na$_{0.89}$Co$_{0.9}$Ni$_{0.1}$O$_2$ and Na$_{0.89}$Co$_{0.9}$Bi$_{0.1}$O$_2$ cobaltates are equal to 1.12 and 0.83 respectively, which is 2.0 and 1.5 times larger, than for Na$_{0.89}$Co$_{0.9}$O$_2$ ($ZT_{1100} = 0.56$), and let us consider the Na$_{0.89}$Co$_{0.9}$O$_2$ derivatives as prospective materials for the high-temperature thermoelectric conversion.
