Abstract

Based on the last year’s DCU-CASIST participation on WMT metrics task, we further improve our model in the following ways: 1) parameter tuning 2) support languages other than English. We tuned our system on all the data of WMT 2010, 2012 and 2013. The tuning results as well as the WMT 2014 test results are reported.

1 Introduction

Automatic evaluation plays a more and more important role in the evolution of machine translation. There are roughly two categories can be seen: namely lexical information based and structural information based.

1) Lexical information based approaches, among which, BLEU (?), Translation Error Rate (TER) (?) and METEOR (?) are the most popular ones and, with simplicity as their merits, cannot adequately reflect the structural level similarity.

2) A lot of structural level based methods have been exploited to overcome the weakness of the lexical based methods, including Syntactic Tree Model(STM)(?), a constituent tree based approach, and Head Word Chain Model(HWCM)(?), a dependency tree based approach. Both of the methods compute the similarity between the sub-trees of the hypothesis and the reference. Owczarzak et al (?; ?; ?) presented a method using the Lexical-Functional Grammar (LFG) dependency tree. MAXSIM (?) and the method proposed by Zhu et al (?) also employed the syntactic information in association with lexical information. As we know that the hypothesis is potentially noisy, and these errors are enlarged through the parsing process. Thus the power of syntactic information could be considerably weakened.

In this paper, based on our attempt on WMT metrics task 2013 (?), we propose a metrics named RED ( REference Dependency based automatic evaluation method). Our metrics employs only the reference dependency tree which contains both the lexical and syntactic information, leaving the hypothesis side unparsed to avoid error propagation.

2 Parameter Tuning

In RED, we use $F$-score as our final score. $F$-score is calculated by Formula (1), where $\alpha$ is a value between 0 and 1.

$$F\text{-score} = \frac{\text{precision} \cdot \text{recall}}{\alpha \cdot \text{precision} + (1 - \alpha) \cdot \text{recall}}$$

(1)

The dependency tree of the reference and the string of the translation are used to calculate the precision and recall. In order to calculate precision, the number of the dep-ngrams (the ngrams obtained from dependency tree?) should be given, but there is no dependency tree for the translation in our method. We know that the number of dep-ngrams has an approximate linear relationship with the length of the sentence, so we use the length of the translation to replace the number of the dep-ngrams in the translation dependency tree. Recall can be calculated directly since we know the number of the dep-ngrams in the reference. The precision and recall are computed as follows.

$$\text{precision}_n = \frac{\sum_{d \in D_n} p(d, \text{hyp})}{\text{len}_h}$$

$$\text{recall}_n = \frac{\sum_{d \in D_n} p(d, \text{hyp})}{\text{count}_n(\text{ref})}$$

$D_n$ is the set of dep-ngrams with the length of $n$. $\text{len}_h$ is the length of the translation. $\text{count}_n(\text{ref})$ is the number of the dep-ngrams with the length of $n$ in the reference. $p(d, \text{hyp})$ is 0 if there is no match and a positive number between 0 and 1 otherwise(?).

1We define two types of dep-ngrams: 1) the head word chain(?); 2) fix-floating(?))
The final score of RED is achieved using Formula (2), in which a weighted sum of the dep-
igrams’ F-score is calculated. \( w_{ngram} \) (0 \( \leq \) \( w_{ngram} \leq 1 \)) is the weight of dep-
igram with the length of \( n \). F-score\(_n\) is the F-score for the dep-
grams with the length of \( n \).

\[
RED = \sum_{n=1}^{N} (w_{ngram} \times F\text{-score}_n) \quad (2)
\]

Other parameters to be tuned includes:

- **Stem and Synonym**

  Stem(?) and synonym (WordNet\(^2\)) are introduced with the following three steps. First, we obtain the alignment with METEOR Aligner (?) in which not only exact match but also stem and synonym are considered. We use stem, synonym and exact match as the three match modules. Second, the alignment is used to match for a dep-ngram. We think the dep-ngram can match with the translation if the following conditions are satisfied.
  1) Each of the words in the dep-ngram has a matched word in the translation according to the alignment; 2) The words in dep-ngram and the matched words in translation appear in the same order; 3) The matched words in translation must be continuous if the dep-
ngram is a fixed-floating ngram. At last, the match module score of a dep-ngram is cal-
culated according to Formula (3). Different match modules have different effects, so we give them different weights.

\[
s_{mod} = \frac{\sum_{i=1}^{n} w_{m_i}}{n}, \quad 0 \leq w_{m_i} \leq 1 \quad (3)
\]

\( m_i \) is the match module (exact, stem or syn-
onym) of the \( i \)th word in a dep-ngram. \( w_{m_i} \) is the match module weight of the \( i \)th word in a dep-ngram. \( n \) is the number of words in a dep-ngram.

- **Paraphrase**

  When introducing paraphrase, we don’t con-
sider the dependency tree of the reference, because paraphrases may not be contained in the head word chain and fixed-floating structures. Therefore we first obtain the align-
ment with METEOR Aligner, only considering paraphrase; Then, the matched paraphrases are extracted from the alignment and defined as paraphrase-ngram. The score of a paraphrase is \( 1 \times w_{par} \), where \( w_{par} \) is the weight of paraphrase-ngram.

- **Function word**

  We introduce a parameter \( w_{fun} \) (0 \( \leq \) \( w_{fun} \leq 1 \)) to distinguish function words and content words. \( w_{fun} \) is the weight of function words. The function word score of a dep-ngram or paraphrase-ngram is computed according to Formula (4).

\[
s_{fun} = \frac{C_{fun} \times w_{fun} + C_{con} \times (1 - w_{fun})}{C_{fun} + C_{con}} \quad (4)
\]

\( C_{fun} \) is the number of function words in the dep-
ngram or paraphrase-ngram. \( C_{con} \) is the number of content words in the dep-ngram or paraphrase-ngram.

\[
REDp = \sum_{n=1}^{N} (w_{ngram} \times F\text{-score}_{pm}) \quad (5)
\]

\[
F\text{-score}_{p} = \frac{\text{precision}_p \cdot \text{recall}_p}{\alpha \cdot \text{precision}_p + (1 - \alpha) \cdot \text{recall}_p} \quad (6)
\]

\( \text{precision}_p \) and \( \text{recall}_p \) in Formula (6) are cal-
culated as follows.

\[
\text{precision}_p = \frac{\text{score}_{par} + \text{score}_{dep}}{\text{len}_n} \quad (\text{len}_n \text{ is the length of the translation.} \quad \text{count}_{n}(ref) \text{ is the number of the dep-ngrams with the length of } n \text{ in the reference.} \quad \text{count}_{n}(par) \text{ is the number of paraphrases with length of } n \text{ in reference.} \quad \text{score}_{par} \text{ is the match score of paraphrase-
grams with the length of } n \text{.} \quad \text{score}_{dep} \text{ is the match score of dep-ngrams with the length of } n \text{.} \quad \text{score}_{par} \text{ and } \text{score}_{dep} \text{ are calculated as follows.})
\]

\[
\text{score}_{par} = \sum_{par \in P_n} (1 \times w_{par} \times s_{fun})
\]

\[
\text{score}_{dep} = \sum_{d \in D_n} (p(d,hyp) \times s_{mod} \times s_{fun})
\]

There are totally nine parameters in RED. We tried two parameter tuning strategies: Genetic search algorithm (?) and a Grid search over two subsets of parameters. The results of Grid search is more stable, therefore our final submission is based upon Grid search. We separate the 9 parameters into two subsets. When searching Subset 1, the parameters in Subset 2 are fixed, and vice versa. Several iterations are executed to finish the parameter tuning process. For system level coefficient score, we set two optimization goals: G.sys.1) to maximize the sum of Spearman’s ρ rank correlation coefficient on system level and Kendall’s τ correlation coefficient on sentence level or G.sys.2) only the former; For sentence level coefficient score, we also set two optimization goals: G.sent.1) the same as G.sys.1, G.sent.2) only the latter part of G.sys.1.

3 Experiments

In this section we report the experimental results of RED on the tuning set, which is the combination of WMT2010, WMT2012 and WMT2013 data set, as well as the test results on the WMT2014. Both the sentence level evaluation and the system level evaluation are conducted to assess the performance of our automatic metrics. At the sentence level evaluation, Kendall’s rank correlation coefficient τ is used. At the system level evaluation, the Spearman’s rank correlation coefficient ρ is used.

3.1 Data

There are four language pairs in WMT2010 and WMT2012 including German-English, Czech-English, French-English and Spanish-English. For WMT2013, except these 4 language pairs, there is also Russian-English. As the test set, WMT 2014 has also five language pairs, but the organizer removed Spanish-English and replace it with Hindi-English. For into-English tasks, we parsed the En-

3.2 Sentence-level Evaluation

Kendall’s rank correlation coefficient $\tau$ is employed to evaluate the correlation of all the MT evaluation metrics and human judgements at the sentence level. A higher value of $\tau$ means a better ranking similarity with the human judges. The correlation scores of are shown in Table 1. Our method performs best when maximum length of dep-n-gram is set to 3, so we present only the results when the maximum length of dep-n-gram equals 3. From Table 1, we can see that: firstly, parameter tuning improve performance significantly on all the three tuning sets; secondly, although the best scores in the column RED-sent are much more than RED-syssent, but the outperform is very small, so by setting these two optimization goals, RED can achieve comparable performance; thirdly, without parameter tuning, RED does not perform well on WMT 2012 and 2013, and even with parameter tuning, RED does not outperform METEOR as much as WMT 2010; lastly, on the test set, RED does not outperform METEOR.

3.3 System-level Evaluation

We also evaluated the RED scores with the human rankings at the system level to further investigate the effectiveness of our metrics. The matching of the words in RED is correlated with the position of the words, so the traditional way of computing system level score, like what BLEU does, is not feasible for RED. Therefore, we resort to the way of adding the sentence level scores together to obtain the system level score. At system level evaluation, we employ Spearman’s rank correlation coefficient $\rho$. The correlations and the average scores are shown in Table 2.

From Table 2, we can see similar trends as in Table 1 with the following difference: firstly, without parameter tuning, RED perform comparably with METEOR on all the three tuning sets; secondly, on test set, RED also perform comparably with METEOR. thirdly, RED perform very bad on Hindi-English, which is a newly introduced task this year.

3.4 Evaluation of English to Other Languages

We evaluate both sentence level and system level score of RED on English to French and German. The reason we only conduct these two languages are that the dependency parsers are more reliable in these two languages. The results are shown in Table 3 and 4.

From Table 3 and 4 we can see that the tuned version of RED still perform slightly better than METEOR with the only exception of system level en-de.

4 Conclusion

In this paper, based on the last year’s DCU-CASICT submission, we further improved our method, namely RED. The experiments are carried out at both sentence-level and system-level using to-English and from-English corpus. The experiment results indicate that although RED achieves better correlation than BLEU, HWCM, TER and comparably performance with METEOR at both sentence level and system level, the performance is not stable on all language pairs, such as the sentence level correlation score of Hindi to
English and the system level score of English to German. To further study the sudden diving of the performance is our future work.
