Steady-State Analysis of Load Balancing with Coxian-2 Distributed Service Times

Xin Liu, Kang Gong and Lei Ying

Abstract

This paper studies load balancing for many-server \(N\) servers) systems assuming Coxian-2 service time and finite buffer with size \(b-1\) (i.e. a server can have at most one job in service and \(b-1\) jobs in queue). We focus on steady-state performance of load balancing policies in the heavy traffic regime such that the load of system is \(\lambda = 1 - N^{-a}\) for \(0 < a < 0.5\). We identify a set of policies that achieve asymptotic zero waiting. The set of policies include several classical policies such as join-the-shortest-queue (JSQ), join-the-idle-queue (JIQ), idle-one-first (I1F) and power-of-\(d\)-choices (Pod) with \(d = O(N^a \log N)\). The proof of the main result is based on Stein’s method and state space collapse. A key technical contribution of this paper is the iterative state space collapse approach that leads to a simple generator approximation when applying Stein’s method.

I. Introduction

Performance analysis of systems with distributed queues is one of the most fundamental and widely-studied problems in queueing theory. Assuming exponential service time, the steady-state performance of various load balancing policies has been analyzed using the mean-field analysis (fluid-limit analysis). Among the most popular policies are: 1) join-the-shortest-queue (JSQ), which routes an incoming job to the least loaded server; 2) join-the-idle-queue (JIQ) [9], [11], which routes an incoming job to an idle server if possible and otherwise to a server chosen uniformly at random; 3) idle-one-first (I1F) [6], which routes an incoming job to an idle server if available and otherwise to a server with one job if available. If all servers have at least two jobs, the job is routed to a randomly selected server; and 4) power-of-\(d\)-choices (Pod) [10], [14], which samples \(d\) servers uniformly at random and dispatches the job to the least loaded server among the \(d\) servers. With general service time distributions, performance analysis of load balancing policies with distributed queues is a much more challenging problem, and remains to be an active research area in queueing theory [7], [10] proposed a mean-field model of the Pod policy under gamma service time distributions without proving the convergence of the stochastic system to the mean-field model. [1], [8], [13] proposed a set of PDE models to approximate load balancing policies under general service times and numerically analyzed key performance metrics (e.g. mean response time). They proved the convergence of the stochastic systems to the corresponding ODEs or PDEs at process-level (over a finite time interval instead of at steady state).

To go beyond the process-level and establish steady-state performance with general service times, a key challenge is to prove that the mean-field system (fluid-system) is stable, i.e. the system converges to a unique equilibrium starting from any initial condition. Under non-exponential service time distributions, the proof of stability often relies on a so-called “monotonicity property”, which requires a partial order of two mean-field systems starting...
from two initial conditions to be maintained over time. In particular, letting \( x(t, y) \) denote the system state at time \( t \) with initial state \( y \), given two initial conditions \( y_1 \succ y_2 \), where "\( \succ \)" is a certain partial order, "monotonicity" states that the partial order \( x(t, y_1) \succ x(t, y_2) \) holds for any \( t \geq 0 \).

Monotonicity does hold under several load balancing policies with non-exponential service time distributions that have a decreasing hazard rate (DHR) [3], [5], [11]. The hazard rate is defined to be \( \frac{f(x)}{1-F(x)} \), where \( f(x) \) is the density function of the service time and \( F(x) \) is the corresponding cumulative distribution function. With DHR, [3] proved the asymptotic independence of queues in the mean-field limit under the PoD load balancing policy, and [11] proved that JIQ achieves asymptotic delay optimality. [12] proved the global stability of the mean-field model of load balancing policies (e.g. PoD) under hyper-exponential distributions with DHR. The key step in [12] is to represent hyper-exponential distribution by a constrained Coxian distribution, where \( \mu_i(1-p_i) \) is decreasing in phase \( i \) (\( \mu_i \) is the service rate in phase \( i \) and \( p_i \) is the probability that a job finishing service in phase \( i \) and entering phase \( i+1 \)). With the alternative representation, monotonicity holds in a certain partial order and the global stability is established.

When service time distributions do not satisfy DHR, only few works established the stability of mean-field systems for very limited light-traffic regimes. For example, [5] relaxed DHR assumption in [11] to any general service distribution but the asymptotic optimality of JIQ only holds when \( \lambda < 0.5 \). The stability of PoD with any general service time distributions with finite second moment has also been established in [3] when the load per server \( \lambda < 1/4 \).

The Coxian-2 distribution considered in this paper does not necessarily satisfy DHR. Under the Coxian-2 service time distribution, each job has two phases (phase 1 and phase 2). When in service, a job finishes phase 1 with rate \( \mu_1 \); and after finishing phase 1, the job leaves the system with probability \( 1 - p \) or enters phase 2 with probability \( p \). If the job enters phase 2, it finishes phase 2 with rate \( \mu_2 \), and leaves the system. Consider a simple system with two servers. Assume the Coxian-2 service time distribution and JSQ is used for load balancing. Consider two different initial conditions for this system as shown in Fig. 1, where jobs in phase 1 are in red color and jobs in phase 2 are in green color. The state of each server can be represented by its queue length and the expected remaining service time of the job in service. Let \( Q^{(i,1)}(t) \) and \( Q^{(i,2)}(t) \) denote the queue length of server \( i \) at time \( t \) with initial condition 1 and 2, respectively, and \( T^{(i,1)}(t), T^{(i,2)}(t) \in \left\{ \frac{1}{\mu_1} + \frac{p}{\mu_2}, \frac{1}{\mu_2} \right\} \) denote the expected remaining service time of the job in service at server \( i \) with initial condition 1 and 2, respectively. At time 0, we have \( Q^{(i,1)}(0) \geq Q^{(i,2)}(0) \) and \( T^{(i,1)}(0) \geq T^{(i,2)}(0) \) for all \( i = 1, 2 \). During the time period \((0, t_1)\), two jobs arrived and were routed to servers according to JSQ, which resulted in the state shown in Fig. 1. Suppose that \( (1 - p)\mu_1 \prec \mu_2 \), then at time \( t_1 \), we have \( T^{(2,1)}(t_1) = \frac{1}{\mu_1} + \frac{p}{\mu_2} \), so the system does not have monotonicity. Note the hazard rate of Coxian-2 distribution is \( \frac{f(x)}{1-F(x)} = \frac{(1-p)\mu_1 + \mu_2 e^{-p(1+p)\mu_2 t}}{1 + e^{-p(1+p)\mu_2 t}} \), which is an increasing function for \( (1 - p)\mu_1 \prec \mu_2 \), therefore, it does not satisfy the DHR property.

In this paper, we analyze the steady-state performance of many server systems assuming Coxian service time distributions and heavy traffic regimes (\( \lambda = 1 - N^{-\alpha} \) for \( 0 < \alpha < 0.5 \)). From the best of our knowledge, this is the first paper that establishes the steady-state performance of general Coxian distributions without DHR in heavy-traffic regimes. In this paper, we develop an iterative state space collapse (SSC) to show the steady-state "lives" in a restricted region
(with a high probability), in which the original system is coupled with a simple system by Stein’s method. With iterative SSC and Stein’s method, we are able to establish several key performance metrics at steady state, including the expected queue length, the probability that a job is allocated to a busy server (waiting probability) and the waiting time. The main results include:

- For any load balancing policy in a policy set $\Pi$ (the detailed definition is given in (2)), which includes join-the-shortest-queue (JSQ), join-the-idle-queue (JIQ), idle-one-first (I1F) and power-of-$d$-choices (Po$^d$) with $d = O(N^\alpha \log N)$, the mean queue length is $\lambda + O\left(\frac{\log N}{\sqrt{N}}\right)$.
- For JSQ and Po$^d$ with $d = O(N^\alpha \log N)$, the waiting probability and the expected waiting time per job are both $O\left(\frac{\log N}{\sqrt{N}}\right)$.
- For JIQ and I1F, the waiting probability is $O\left(\frac{1}{N^{0.5-\alpha} \log N}\right)$.

## II. Model and Main Results

We consider a many-server system with $N$ homogeneous servers, where job arrival follows a Poisson process with rate $\lambda N$ with $\lambda = 1 - N^{-\alpha}, 0 < \alpha < 0.5$ and service times follow Coxian-2 distribution ($\mu_1, \mu_2, p$) as shown in Fig. 2, where $\mu_m > 0$ is the rate a job finishes phase $m$ when in service and $0 \leq p < 1$ is the probability that a job enters phase 2 after finishing phase 1.

![Fig. 2: Coxian-2 distribution.](image)

Without loss of generality, we assume the mean service time to be one, i.e.

$$\frac{1}{\mu_1} + \frac{p}{\mu_2} = 1.$$ 

As shown in Fig. 3, an arrival job is colored with black before processed by the server, and colored with red and green when it is in phase 1 and phase 2 in service, respectively. Each
server has a buffer of size $b - 1$, so can hold at most $b$ jobs ($b - 1$ in the buffer and one in service).

Let $Q_{j,m}(t)$ ($m = 1, 2$) denote the fraction of servers which have $j$ jobs at time $t$ and the one in service is in phase $m$. For convenience, we define $Q_{0,1}(t)$ to be the fraction of servers that are idle at time $t$ and $Q_{0,2}(t) = 0$. Furthermore, define $Q(t)$ to be a $b \times 2$ matrix such that the $(j,m)$th entry of the matrix is $Q_{j,m}(t)$. Define $S_{i,m}(t) = \sum_{j \geq i} Q_{j,m}(t)$ and $S_i(t) = \sum_{m=1}^{2} S_{i,m}(t)$. In other words, $S_{i,m}(t)$ is the fraction of servers which have at least $i$ jobs and the job in service is in phase $m$ at time $t$ and $S_i(t)$ is the fraction of servers with at least $i$ jobs at time $t$. Furthermore define $S(t)$ to be a $b \times 2$ matrix such that the $(j,m)$th entry of the matrix is $S_{j,m}(t)$. Note $Q(t)$ and $S(t)$ have an one-to-one mapping. We consider load balancing policies which dispatch jobs to servers based on $Q(t)$ (or $S(t)$) and under which the finite-state CTMC $\{Q(t), t \geq 0\}$ (or $\{S(t), t \geq 0\}$) is irreducible, and so it has a unique stationary distribution. The load balancing policies include JSQ, JIQ, I1F and Pod.

Let $Q_{i,m}$ denote $Q_{i,m}(t)$ at steady state. We further define $S_{i,m} = \sum_{j \geq i} Q_{i,m}$ and $S_i = \sum_{m} S_{i,m}$. In other words, $S_{i,m}$ is the fraction of servers which have at least $i$ jobs and the job in service is in phase $m$ and $S_i$ is the fraction of servers with at least $i$ jobs at steady state. We illustrate the state representation $S_{i,m}$ in Fig. 4 and Table I.

Fig. 4: Illustrations of states $S_{i,m}$. 
Define $S$ to be a $b \times 2$ random matrix such that the $(i, m)$th entry is $s_{i,m}$ and let $s \in \mathbb{R}^{b \times 2}$ denote a realization of $S$. Define $S^{(N)}$ to be a set of $s$ such that

$$S^{(N)} = \left\{ s \mid 1 \geq s_{1,m} \geq \cdots \geq s_{b,m}, \ 1 \geq \sum_{m=1}^{2} s_{1,m}, \ Ns_{i,m} \in \mathbb{N}, \ \forall i, m \right\}. \quad (1)$$

Let $A_1(s)$ denote the probability that an incoming job is routed to a busy server conditioned on that the system is in state $s \in S^{(N)}$; i.e.

$$A_1(s) = \mathbb{P}(\text{an incoming job is routed to a busy server} | S(t) = s).$$

Among the load balancing policies considered in this paper, define a subset

$$\Pi = \left\{ \pi \mid \text{Under policy } \pi, A_1(s) \leq \frac{1}{\sqrt{N}} \ \forall s \in S^{(N)}, \right\}.$$

Our main result of this paper is the following theorem.

**Theorem 1.** Define $w_u = \max\{(1-p)\mu_1, \mu_2\}, w_l = \min\{(1-p)\mu_1, \mu_2\}, \mu_{\text{max}} = \max\{\mu_1, \mu_2\},$ and $k = \left(1 + \frac{w_u}{w_l}\right)\left(1 + \mu_1 + \mu_2 + 2\mu_1\right).$ Under any load balancing policy in $\Pi$, the following bound holds

$$\mathbb{E}
\left[
\max
\left\{
\sum_{i=1}^{b} S_i - \lambda - \frac{k \log N}{\sqrt{N}}, 0\right\}
\right]
\leq \frac{7\mu_{\text{max}}}{\sqrt{N} \log N},$$

when a large $N$ satisfying

$$\frac{w_l N^{0.5-a}}{1 + \mu_1 + \mu_2} \geq \log N \geq \frac{3.5}{\min\left(\frac{\mu_1}{16\mu_{\text{max}}}, \frac{\mu_2}{12\mu_{\text{max}}}, \frac{\mu_1\mu_2}{40\mu_{\text{max}}}\right)}.$$ \hfill (4)

Note that the condition $A_1(s) \leq \frac{1}{\sqrt{N}}$ for $s$ such that $s_1 \leq \lambda + \frac{1 + \mu_1 + \mu_2}{w_l} \frac{\log N}{\sqrt{N}}$ means that an incoming job is routed to an idle server with probability at least $1 - \frac{1}{\sqrt{N}}$ when at least $\frac{1}{N^a} - \frac{1 + \mu_1 + \mu_2}{w_l} \frac{\log N}{\sqrt{N}}$ fraction of servers are idle. There are several well-known policies that satisfy this condition.

- **Join-the-Shortest-Queue (JSQ):** JSQ routes an incoming job to the least loaded server in the system. Therefore, $A_1(s) = 0$ when $s_1 < 1$.
- **Idle-One-First (I1F)** [6]: I1F routes an incoming job to an idle server if available; and otherwise to a server with one job if available. If all servers have at least two jobs, the job is routed to a randomly selected server. Therefore, $A_1(s) = 0$ when $s_1 < 1$.  

| $Q_{1,1}$ | $Q_{2,1}$ | $Q_{3,1}$ | $Q_{1,2}$ | $Q_{2,2}$ | $Q_{3,2}$ | $Q_{4,2}$ | $Q_{5,2}$ |
|----------|----------|----------|----------|----------|----------|----------|----------|
| 0.2      | 0.2      | 0.1      | 0.1      | 0.1      | 0        | 0        | 0.2      |
| $S_{1,1}$ | $S_{2,1}$ | $S_{3,1}$ | $S_{1,2}$ | $S_{2,2}$ | $S_{3,2}$ | $S_{4,2}$ | $S_{5,2}$ |
| 0.5      | 0.3      | 0.1      | 0.5      | 0.4      | 0.3      | 0.2      | 0.2      |

**TABLE I:** Values of $Q_{i,m}$ and $S_{i,m}$ in Fig. 4.
• **Join-the-Idle-Queue (JIQ)** [9]: JIQ routes an incoming job to an idle server if possible and otherwise, routes to a server chosen uniformly at random. Therefore, $A_1(s) = 0$ when $s_1 < 1$.

• **Power-of-$d$-Choices (Pod)** [10], [14]: Pod samples $d$ servers uniformly at random and dispatches the job to the least loaded server among the $d$ servers. Ties are broken uniformly at random. When $d \geq \mu_1 N^{\alpha} \log N$, $A_1(s) \leq \frac{1 + \mu_1 + \mu_2 \log N}{\mu_1} \sqrt{N}$.

A direct consequence of Theorem 1 is asymptotic zero waiting at steady state. Let $\mathcal{W}$ denote the event that an incoming job is routed to a busy server in a system with $N$ servers, and $P(\mathcal{W})$ denote the probability of this event at steady-state. Let $B$ denote the event that an incoming job is blocked (discarded) and $P(B)$ denote the probability of this event at steady-state. Note that the occurrence of event $B$ implies the occurrence of event $\mathcal{W}$ because a job is blocked when being routed to a server with $b$ jobs. Furthermore, let $W$ denote the waiting time of a job (when the job is not dropped). We have the following results based on the main theorem.

**Corollary 1.** The following results hold when a large $N$ satisfying (4) that

- Under JSQ and Pod with $d \geq \mu_1 N^{\alpha} \log N$ such that $\sqrt{\frac{N}{b-\lambda}} \geq \frac{8 k \log N}{b-\lambda} + \frac{8 b N^{0.5-\alpha}}{\mu_1}$, we have

$\mathbb{E}[W] \leq \frac{2k \log N}{\sqrt{N}} + \frac{14 \mu_{\max}}{\sqrt{N \log N}}$, \hspace{1cm} (5)

$P(\mathcal{W}) \leq \frac{1}{{N}} + \frac{\mu_{\max}}{\lambda} \left( \frac{k \log N}{\sqrt{N}} + \frac{7 \mu_{\max}}{\sqrt{N \log N}} + \frac{8 \mu_{\max}}{b-\lambda} \right)$. \hspace{1cm} (6)

- Under JIQ and IIF such that $N^{0.5-\alpha} \geq 2k \log N$,

$P(\mathcal{W}) \leq \frac{14 \mu_{\max}}{N^{0.5-\alpha} \log N}$. \hspace{1cm} (7)

The proof of this corollary is an application of Little’s law and Markov’s inequality, and can be found in the Section H.

### III. Proof of Theorem 1 under JSQ

In this section, we present the proof of our main theorem for JSQ, which is organized along the three key ingredients: 1) generator approximation; 2) gradient bounds; 3) state space collapse. The proof for other load balancing policies is similar and will be discussed in Section IV.

####  A. Generator Approximation

Define $e_{i,m} \in \mathbb{R}^{b \times 2}$ to be a $b \times 2$-dimensional matrix such that the $(i,m)$th entry is $1/N$ and all other entries are zero.

Given the state $s$ of the CTMC and the corresponding $q$, the following events trigger a transition from state $s$.
• Event 1: A job arrives and is routed to a server that it has \( i-1 \) jobs and the job in service is in phase 1. When this occurs, \( q_{i,1} \) increases by \( 1/N \), and \( q_{i-1,1} \) decreases by \( 1/N \), so the CTMC has the following transition:

\[
q \to q + e_{i,1} - e_{i-1,1}, \\
s \to s + e_{i,1}.
\]

This transition occurs with rate

\[
\lambda N \frac{q_{i-1,1}}{q_{i-1}} \mathbb{1}_{\{s_{i-1}=1, s_i < 1\}},
\]

where \( \frac{q_{i-1,1}}{q_{i-1}} \) is the probability that the server which receives the job is serving a job in phase 1 conditioned on the job is routed to a server with \( i-1 \) jobs, and \( \{s_{i-1} = 1, s_i < 1\} \) implies that the shortest queue in the system has length \( i-1 \).

• Event 2: A job arrives and is routed to a server such that it has \( i-1 \) jobs and the job in service is in phase 2. When this occurs, \( q_{i,2} \) increases by \( 1/N \), and \( q_{i-1,2} \) decreases by \( 1/N \), so the CTMC has the following transition:

\[
q \to q + e_{i,2} - e_{i-1,2}, \\
s \to s + e_{i,2}.
\]

This transition occurs with rate

\[
\lambda N \frac{q_{i-1,2}}{q_{i-1}} \mathbb{1}_{\{s_{i-1}=1, s_i < 1\}},
\]

where \( \frac{q_{i-1,2}}{q_{i-1}} \) is the probability that the server which receives the job is serving a job in phase 2 conditioned on the job is routed to a server with \( i-1 \) jobs, and \( \{s_{i-1} = 1, s_i < 1\} \) implies that the shortest queue in the system has length \( i-1 \).

• Event 3: A server, which has \( i \) jobs, finishes phase 1 of the job in service. The job leaves the system without entering phase 2. When this occurs, \( q_{i,1} \) decreases by \( 1/N \) and \( q_{i-1,1} \) increases by \( 1/N \), so the CTMC has the following transition:

\[
q \to q - e_{i,1} + e_{i-1,1}, \\
s \to s - e_{i,1}.
\]

This transition occurs with rate

\[
\mu_1 N q_{i,1} (1 - p),
\]

where \( (1 - p) \) is the probability that a job finishes phase 1 and departures without entering phase 2.

• Event 4: A server, which has \( i \) jobs, finishes phase 1 of the job in service. The job enters phase 2. When this occurs, a server in state \((i,1)\) transits to state \((i,2)\), so \( q_{i,1} \) decreases by \( 1/N \) and \( q_{i,2} \) increases by \( 1/N \). Therefore, the CTMC has the following transition:

\[
q \to q - e_{i,1} + e_{i,2}, \\
s \to s - \sum_{j=1}^{i} e_{j,1} + \sum_{j=1}^{i} e_{j,2}.
\]
where the transition of $s$ can be verified based on the definition $s_{i,m} = \sum_{j \geq i} q_{j,m}$ so $s_{j,1}$ decreases by $1/N$ for any $j \leq i$ and $s_{j,2}$ increases by $1/N$ for any $j \leq i$. This event occurs with rate
\[
\mu_1 N q_{i,1} p,
\]
where $p$ is the probability that a job enters phase 2 after finishing phase 1.

- Event 5: A server, which has $i$ jobs, finishes phase 2 of the job in service. The job leaves the system. When this occurs, $q_{i,2}$ decreases by $1/N$ and $q_{i-1,1}$ increases by $1/N$ (because the server starts a new job in phase 1 and the event when $i = 1$ means the fraction of idle server increase by $1/N$), so the CTMC has the following transition:

\[
q \rightarrow q - e_{i,2} + e_{i-1,1},
\]
\[
s \rightarrow s - \sum_{j=1}^{i} e_{j,2} + \sum_{j=1}^{i-1} e_{j,1}.
\]

This transition occurs with rate
\[
\mu_2 N q_{i,2}.
\]

We illustrate local state transitions related to state $s$ in Fig. 5.

Fig. 5: Illustrations of state transitions for any $i$ with $1 \leq i \leq b$. 
Let $G$ be the generator of CTMC ($S(t) : t \geq 0$). Given function $f : S^{(N)} \rightarrow \mathbb{R}$, we have

$$
Gf(s) = \sum_{i=1}^{b} \left[ \lambda N q_{i-1,1} \mathbb{1}_{\{s_{i-1} = 1, s_i < 1\}} (f(s + e_{i,1}) - f(s)) + \lambda N q_{i-1,2} \mathbb{1}_{\{s_{i-1} = 1, s_i < 1\}} (f(s + e_{i,2}) - f(s)) + (1 - p) \mu_1 N q_{i,1} (f(s - e_{i,1}) - f(s)) + p \mu_1 N q_{i,1} \left( f \left( s - \sum_{j=1}^{i} e_{j,1} + \sum_{j=1}^{i} e_{j,2} \right) - f(s) \right) + \mu_2 N q_{i,2} \left( f \left( s - \sum_{j=1}^{i-1} e_{j,2} + \sum_{j=1}^{i-1} e_{j,1} \right) - f(s) \right) \right]
$$

For any bounded function $f : S^{(N)} \rightarrow \mathbb{R}$,

$$
\mathbb{E}[Gf(S)] = 0,
$$

which can be easily verified by using the global balance equations and the fact that $S$ represents the steady-state of the CTMC.

To understand the steady-state performance of a load balancing policy, we will establish an upper bound on the distance function in (3):

$$
\max \left\{ \sum_{i=1}^{b} S_i - \eta, 0 \right\},
$$

with

$$
\eta = \lambda + \frac{k \log N}{\sqrt{N}}.
$$

The upper bound measures the quantity that the total number of jobs in the system ($N \sum_{i=1}^{b} S_i$) exceeds $N \lambda + k \sqrt{N} \log N$ at steady state, and can be used to bound the probability that an incoming job is routed to an idle server in Corollary 1.

We consider a simple fluid system with arrival rate $\lambda$ and departure rate $\lambda + \frac{\log N}{\sqrt{N}}$, i.e.

$$
\dot{x} = -\frac{\log N}{\sqrt{N}},
$$

and function $g(x)$ which is the solution of the following Stein’s equation [16]:

$$
g'(x) \left( -\frac{\log N}{\sqrt{N}} \right) = \max \{x - \eta, 0\}, \forall x,
$$

where $g'(x) = \frac{dg(x)}{dx}$. The left-hand side of (15) can be viewed as applying the generator of the simple fluid system to function $g(x)$, i.e.

$$
\frac{dg(x)}{dt} = g'(x) \dot{x} = g'(x) \left( -\frac{\log N}{\sqrt{N}} \right).
$$
It is easy to verify that the solution to (15) is
\[ g(x) = -\frac{\sqrt{N}}{2\log N} (x - \eta)^2 \mathbb{I}_{x \geq \eta}, \] (16)
and
\[ g'(x) = -\frac{\sqrt{N}}{\log N} (x - \eta) \mathbb{I}_{x \geq \eta}. \] (17)

We note that the simple fluid system is a one-dimensional system and the stochastic system is \( b \times 2 \)-dimensional. In order to couple these two systems, we define
\[ f(s) = g \left( \sum_{i=1}^{b} \sum_{m=1}^{2} s_{i,m} \right), \] (18)
and invoke \( f(s) \) in Stein’s method.

Since \( \sum_{i=1}^{b} \sum_{m=1}^{2} s_{i,m} = \sum_{i=1}^{b} s_{i} \leq b \) for \( s \in S(N) \), and \( f(s) \) is bounded for \( s \in S(N) \), we have
\[ \mathbb{E}[Gf(S)] = \mathbb{E} \left[ Gg \left( \sum_{i=1}^{b} \sum_{m=1}^{2} S_{i,m} \right) \right] = 0. \] (19)

Now define
\[ h(x) = \max \{ x - \eta, 0 \}. \]

Based on (15) and (19), we obtain
\[ \mathbb{E} \left[ h \left( \sum_{i=1}^{b} \sum_{m=1}^{2} S_{i,m} \right) \right] = \mathbb{E} \left[ g' \left( \sum_{i=1}^{b} \sum_{m=1}^{2} S_{i,m} \right) \left( -\frac{\log N}{\sqrt{N}} \right) - Gg \left( \sum_{i=1}^{b} \sum_{m=1}^{2} S_{i,m} \right) \right]. \] (20)

Note that according to the definition of \( f(s) \) in (18), \( e_{j,1} \) and \( e_{j,2} \), we have
\[ f(s + e_{j,1}) = g \left( \sum_{i=1}^{b} \sum_{m=1}^{2} s_{i,m} + \frac{1}{N} \right), \quad f(s + e_{j,2}) = g \left( \sum_{i=1}^{b} \sum_{m=1}^{2} s_{i,m} + \frac{1}{N} \right) \]
and
\[ f(s - e_{j,1}) = g \left( \sum_{i=1}^{b} \sum_{m=1}^{2} s_{i,m} - \frac{1}{N} \right), \quad f(s - e_{j,2}) = g \left( \sum_{i=1}^{b} \sum_{m=1}^{2} s_{i,m} - \frac{1}{N} \right) \]
for any \( 1 \leq j \leq b \). Therefore,
\[ Gg \left( \sum_{i=1}^{b} \sum_{m=1}^{2} s_{i,m} \right) \]
\[ = N \lambda \left( 1 - \mathbb{I}_{\{s_b = 1\}} \right) \left( g \left( \sum_{i=1}^{b} \sum_{m=1}^{2} s_{i,m} + \frac{1}{N} \right) - g \left( \sum_{i=1}^{b} \sum_{m=1}^{2} s_{i,m} \right) \right) \]
\[ + N ((1 - p) \mu_1 s_{1,1} + \mu_2 s_{2,2}) \left( g \left( \sum_{i=1}^{b} \sum_{m=1}^{2} s_{i,m} - \frac{1}{N} \right) - g \left( \sum_{i=1}^{b} \sum_{m=1}^{2} s_{i,m} \right) \right), \]
where the first term represents the transitions when a job arrives and the second term repre-
sents the transitions when a job departures from the system. Note \((1 - p)\mu_1 s_{1,1} + \mu_2 s_{1,2}\) are
the rates at which jobs leave the system when in phase 1 and phase 2, respectively in the state
s. Therefore, \((1 - p)\mu_1 s_{1,1} + \mu_2 s_{1,2}\) is the total departure rate. Define \(d_1 = (1 - p)\mu_1 s_{1,1} + \mu_2 s_{1,2}\)
and its stochastic correspondence \(D_1 = (1 - p)\mu_1 s_{1,1} + \mu_2 s_{1,2}\) for simple notations.

Substituting the equation above to (20), we have

\[
\mathbb{E} \left[ h \left( \sum_{i=1}^{b} \sum_{m=1}^{2} S_{i,m} \right) \right]
\]

\[
= \mathbb{E} \left[ g' \left( \sum_{i=1}^{b} \sum_{m=1}^{2} S_{i,m} \right) \left( -\frac{\log N}{\sqrt{N}} \right) \right]
\]

\[
- N\lambda (1 - \mathbb{I}_{\{S_0 = 1\}}) \left( g \left( \sum_{i=1}^{b} \sum_{m=1}^{2} S_{i,m} \right) + \frac{1}{N} \right) - g \left( \sum_{i=1}^{b} \sum_{m=1}^{2} S_{i,m} \right)
\]

\[
- ND_1 \left( g \left( \sum_{i=1}^{b} \sum_{m=1}^{2} S_{i,m} - \frac{1}{N} \right) - g \left( \sum_{i=1}^{b} \sum_{m=1}^{2} S_{i,m} \right) \right). \tag{21}
\]

From the closed-forms of \(g\) and \(g'\) in (16) and (17), note that for any \(x < \eta\),

\[
g(x) = g'(x) = 0.
\]

Also note that when \(x > \eta + \frac{1}{N}\),

\[
g'(x) = -\sqrt{\frac{N}{\log N}} (x - \eta), \tag{22}
\]

so for \(x > \eta + \frac{1}{N}\),

\[
g''(x) = -\sqrt{\frac{N}{\log N}}. \tag{23}
\]

By using mean-value theorem in the region \(T_1 = \{x \mid \eta - \frac{1}{N} \leq x \leq \eta + \frac{1}{N} \}\) and Taylor
theorem in the region \(T_2 = \{x \mid x > \eta + \frac{1}{N} \}\), we have

\[
g(x + \frac{1}{N}) - g(x) = \left( g(x + \frac{1}{N}) - g(x) \right) \left( \mathbb{I}_{x \in T_1} + \mathbb{I}_{x \in T_2} \right)
\]

\[
= \frac{g'(\xi)}{N} \mathbb{I}_{x \in T_1} + \left( \frac{g'(x)}{N} + \frac{g''(\xi)}{2N^2} \right) \mathbb{I}_{x \in T_2} \tag{24}
\]

\[
g(x - \frac{1}{N}) - g(x) = \left( g(x - \frac{1}{N}) - g(x) \right) \left( \mathbb{I}_{x \in T_1} + \mathbb{I}_{x \in T_2} \right)
\]

\[
= -\frac{g'(\xi)}{N} \mathbb{I}_{x \in T_1} + \left( -\frac{g'(x)}{N} + \frac{g''(\xi)}{2N^2} \right) \mathbb{I}_{x \in T_2} \tag{25}
\]

where \(\xi, \xi \in (x, x + \frac{1}{N})\) and \(\xi, \xi \in (x - \frac{1}{N}, x)\). Substitute (24) and (25) into the generator
difference in (21), we have

\[
\mathbb{E} \left[ h \left( \sum_{i=1}^{b} S_i \right) \right] = I_1 + I_2 + I_3. \tag{26}
\]
with
\[ J_1 = \mathbb{E} \left[ g' \left( \sum_{i=1}^{b} S_i \right) \left( \lambda \mathbb{I}_{\{ S_b = 1 \}} - \lambda - \frac{\log N}{\sqrt{N}} + D_1 \right) \mathbb{I}_{\sum_{i=1}^{b} S_i \in T_2} \right], \]  
\[ J_2 = \mathbb{E} \left[ \left( g' \left( \sum_{i=1}^{b} S_i \right) \left( -\log N \sqrt{N} \right) - \lambda \mathbb{I}_{\{ S_b = 1 \}} g' (\xi) + D_1 g' (\tilde{\xi}) \right) \mathbb{I}_{\sum_{i=1}^{b} S_i \in T_1} \right] \]  
\[ J_3 = -\mathbb{E} \left[ \frac{1}{2N} \left( \lambda \mathbb{I}_{\{ S_b = 1 \}} g'' (\zeta) + D_1 g'' (\tilde{\zeta}) \right) \mathbb{I}_{\sum_{i=1}^{b} S_i \in T_2} \right]. \]  

Note that in (28) and (29), we have that 
\[ \xi, \zeta \in \left( \sum_{i=1}^{b} S_i, \sum_{i=1}^{b} S_i + \frac{1}{N} \right) \text{ and } \tilde{\xi}, \tilde{\zeta} \in \left( \sum_{i=1}^{b} S_i - \frac{1}{N}, \sum_{i=1}^{b} S_i \right) \]
are random variables whose values depend on \( \sum_{i=1}^{b} S_i \). We do not include \( \sum_{i=1}^{b} S_i \) in the notation for simplicity.

To establish the main result in Theorem 1, we need to provide the upper bounds on (27), (28) and (29). In the following subsection III-B, we study \( g' \) and \( g'' \) to bound the terms in (28) and (29); In the subsection III-C, we study SSC to bound the term in (27).

B. Gradient Bounds

To bound \( J_2 \) in (28) and \( J_3 \) in (29), we summarize bounds on \( g' \) and \( g'' \) in the following two lemmas.

**Lemma 1.** Given \( x \in [\eta - \frac{2}{\sqrt{N}}, \eta + \frac{2}{\sqrt{N}}] \), we have 
\[ |g'(x)| \leq \frac{2}{\sqrt{N} \log N}. \]  
\[ \square \]

**Lemma 2.** For \( x > \eta \), we have 
\[ |g''(x)| \leq \frac{\sqrt{N}}{\log N}. \]  
\[ \square \]

Based on the bounds on \( g' \) in Lemma 1 and \( g'' \) in Lemma 2, we provide the upper bound on \( J_2 + J_3 \) in the following lemma.

**Lemma 3.** For \( g(\cdot) \) defined in (16), we have 
\[ J_2 + J_3 \leq \frac{6 \mu_{\max}}{\sqrt{N} \log N}. \]  
\[ \square \]

The proofs of the lemmas above are presented in Appendix A.
C. State Space Collapse (SSC)

In this subsection, we analyze $J_1$ in (27):

$$\mathbb{E} \left[ g' \left( \sum_{i=1}^b S_i \right) \left( \lambda \mathbb{I}_{\{S_b=1\}} - \lambda - \frac{\log N}{\sqrt{N}} + D_1 \right) \mathbb{I}_{\sum_{i=1}^b S_i \geq \eta + \frac{1}{N}} \right] = \mathbb{E} \left[ \frac{\sqrt{N}}{\log N} h \left( \sum_{i=1}^b S_i \right) \left( -\lambda \mathbb{I}_{\{S_b=1\}} + \lambda + \frac{\log N}{\sqrt{N}} - D_1 \right) \mathbb{I}_{\sum_{i=1}^b S_i \geq \eta + \frac{1}{N}} \right] \leq \mathbb{E} \left[ \frac{\sqrt{N}}{\log N} h \left( \sum_{i=1}^b S_i \right) \left( \lambda + \frac{\log N}{\sqrt{N}} - D_1 \right) \mathbb{I}_{\sum_{i=1}^b S_i \geq \eta + \frac{1}{N}} \right],$$

where the equality is due to Stein’s equation (15), and the inequality holds because

$$\frac{\sqrt{N}}{\log N} h \left( \sum_{i=1}^b S_i \right) \mathbb{I}_{\sum_{i=1}^b S_i \geq \eta + \frac{1}{N}} \geq 0.$$

We first focus on

$$\left( \lambda + \frac{\log N}{\sqrt{N}} - (1-p)\mu_1 s_{1,1} - \mu_2 s_{1,2} \right) \mathbb{I}_{\sum_{i=1}^b S_i \geq \eta + \frac{1}{N}},$$

where we recall $\eta = \lambda + \frac{k \log N}{\sqrt{N}}$ and $d_1 = (1-p)\mu_1 s_{1,1} + \mu_2 s_{1,2}$ is the total departure rate when the system in the state $s$.

We consider two cases: $s \in S_{ssc}$ and $s \notin S_{ssc}$, where

$$S_{ssc} = S_{ssc_1} \cup S_{ssc_2},$$

and

$$S_{ssc_1} = \left\{ s \mid s_1 \geq \lambda + \left( \frac{1 + \mu_1 + \mu_2}{w_1} - \mu_1 \right) \frac{\log N}{\sqrt{N}}, \quad s_{1,1} \geq \frac{\lambda}{\mu_1} - \frac{\log N}{\sqrt{N}} \right\},$$

$$S_{ssc_2} = \left\{ s \mid \sum_{i=1}^b s_i \leq \lambda + \frac{k \log N}{\sqrt{N}} \right\}.$$

- **Case 1**: $S_{ssc_1}$ is shown as the gray region in Fig. 6. Any $s \in S_{ssc_1}$ satisfies

$$(1-p)\mu_1 s_{1,1} + \mu_2 s_{1,2} \geq \lambda + \frac{\log N}{\sqrt{N}},$$

so

$$\left( \lambda + \frac{\log N}{\sqrt{N}} - (1-p)\mu_1 s_{1,1} - \mu_2 s_{1,2} \right) \mathbb{I}_{\sum_{i=1}^b S_i \geq \eta + \frac{1}{N}} \leq 0$$

for any $s \in S_{ssc_1}$. The details are presented in Lemma 4. When $s \in S_{ssc_2}$,

$$\mathbb{I}_{\sum_{i=1}^b S_i \geq \eta + \frac{1}{N}} = 0,$$

so

$$\left( \lambda + \frac{\log N}{\sqrt{N}} - (1-p)\mu_1 s_{1,1} - \mu_2 s_{1,2} \right) \mathbb{I}_{\sum_{i=1}^b S_i \geq \eta + \frac{1}{N}} = 0$$

for any $s \in S_{ssc_2}$.

- **Case 2**: We will show that

$$\mathbb{P} (S \notin S_{ssc}) \leq \frac{3}{N^2}.$$
in Lemma 5 using an iterative state space collapse approach.

**Lemma 4.** For any \( s \in S_{ssc_1} \),

\[
\left( \lambda + \frac{\log N}{\sqrt{N}} - (1 - p)\mu_1 s_{1,1} - \mu_2 s_{1,2} \right) \sum_{i=1}^p \frac{1}{s_i} > \frac{k \log N}{\sqrt{N}} \leq 0
\]

The proof of Lemma 4 can be found in Appendix C.

**Lemma 5.** For a large \( N \) such that \( \log N \geq 3.5 \min \left( \frac{\mu_1}{\mu_{\text{max}}}, \frac{\mu_2}{2 \mu_{\text{max}}}, \frac{\mu_1 \mu_2}{40 \mu_{\text{max}}} \right) \), we have

\[
P(S \notin S_{ssc}) \leq \frac{3}{N^2}.
\]

The proof of Lemma 5 is based on an “iterative” procedure to establish state space collapse, which is achieved by proving a sequence of four lemmas. The detailed proof of Lemma 5 - Lemma 9 can be found in Appendix C.

**Lemma 6 (An Upper Bound on \( S_{1,2} \)).**

\[
P \left( S_{1,2} \leq \frac{p \lambda}{\mu_2} + \frac{\log N}{2 \sqrt{N}} \right) \geq 1 - e^{-\frac{p \mu_2 \log^2 N}{40 \mu_{\text{max}}}}.
\]

**Lemma 7 (A Lower Bound on \( S_{1,1} \)).**

\[
P \left( S_{1,1} \geq \frac{\lambda}{\mu_1} - \frac{\log N}{\sqrt{N}} \right) \geq 1 - \frac{5 \sqrt{N}}{\mu_1 \log N} e^{-\min \left( \frac{\mu_1}{16 \mu_{\text{max}}}, \frac{\mu_1 \mu_2}{40 \mu_{\text{max}}} \right) \log^2 N}.
\]

**Lemma 8 (A Lower Bound on \( S_{1,2} \)).**

\[
P \left( S_{1,2} \geq \frac{p \lambda}{\mu_2} - \frac{\mu_1 \log N}{\sqrt{N}} \right) \geq 1 - \frac{16}{\mu_1 \mu_2 \log^2 N} e^{-\min \left( \frac{\mu_1}{16 \mu_{\text{max}}}, \frac{\mu_2}{12 \mu_{\text{max}}}, \frac{\mu_1 \mu_2}{40 \mu_{\text{max}}} \right) \log^2 N}.
\]
Lemma 9 (A Lower Bound on $S_1$ via $\sum_{i=2}^{b} S_i$).

$$
\mathbb{P} \left( \min \left\{ \lambda + \frac{k \log N}{\sqrt{N}} - S_1, \sum_{i=2}^{b} S_i \right\} \leq \frac{(c_1 + \mu_1) \log N}{\sqrt{N}} \right) \\
\geq 1 - \frac{34}{\mu_1^2 \mu_2 \log^3 N} e^{-\min\left( \frac{\mu_1}{w_{\mu_{\max}}} \frac{\mu_2}{w_{\mu_{\max}}} \frac{\mu_1 \mu_2}{w_{\mu_{\max}}} \right) \log^2 N}
$$

for $\log N \geq \frac{1}{\min\{\mu_1, \mu_2\}}$, where $k = \left(1 + \frac{w_{b} \mu}{w_{b}}\right) \left(\frac{1+\mu_1+\mu_2}{w_{b}} + 2\mu_1\right)$ and $c_1 = \frac{w_{b} \mu}{w_{b}} \left(\frac{1+\mu_1+\mu_2}{w_{b}} + 2\mu_1\right) + 2\mu_1$.

**Remark:** An important contribution of this paper is the iterative state collapse method we use to prove Lemma 5. The method continues refining the state space in which the system stays with a high probability at steady-state. Fig. 7 illustrates the iterative state-space collapse in Lemma 6 - Lemma 8. We first show in Lemma 6 that with a high probability, $S_{1,2} \leq \frac{p \lambda}{\mu_2} + \frac{\log N}{2\sqrt{N}}$ at steady-state. Then in the reduced state space $\left( S_{1,2} \leq \frac{p \lambda}{\mu_2} + \frac{\log N}{2\sqrt{N}} \right)$, we further show in Lemma 7 that $S_{1,1} \geq \frac{\lambda}{\mu_1} - \frac{\log N}{\sqrt{N}}$ with a high probability at steady state. We then further establish in Lemma 6 that $S_{1,2} \geq \frac{p \lambda}{\mu_2} - \frac{\mu_1 \log N}{\sqrt{N}}$ with a high probability at steady state in the reduced state space.

Fig. 7: Iterative State-Space Collapse to Show that $S_{1,1}$ and $S_{1,2}$ are in a Smaller State-Space (the Gray Region) at Steady-State
D. Proof of Theorem 1 under JSQ

Based on Lemma 4 and Lemma 5, we can establish the following bound on (30), which is a upper bound on $J_1$ in (27),

$$
\mathbb{E}\left[ \frac{\sqrt{N}}{\log N} \left( \sum_{i=1}^{b} \frac{2}{\sqrt{N}} S_{i,m} \right) \left( \lambda + \frac{\log N}{\sqrt{N}} - D_1 \right) \mathbb{I}_{\sum_{i=1}^{b} S_{i}>\eta + \frac{1}{N}} \right] = \mathbb{E}\left[ \frac{\sqrt{N}}{\log N} \left( \sum_{i=1}^{b} S_{i} - \eta \right) \left( \lambda + \frac{\log N}{\sqrt{N}} - D_1 \right) \mathbb{I}_{S \in S_{sc}} \mathbb{I}_{\sum_{i=1}^{b} S_{i}>\eta + \frac{1}{N}} \right] + \mathbb{E}\left[ \frac{\sqrt{N}}{\log N} \left( \sum_{i=1}^{b} S_{i} - \eta \right) \left( \lambda + \frac{\log N}{\sqrt{N}} - D_1 \right) \mathbb{I}_{S \notin S_{sc}} \mathbb{I}_{\sum_{i=1}^{b} S_{i}>\eta + \frac{1}{N}} \right] \leq \frac{3b}{N^{1.5} \log N}
$$

(32)

where we have $\left( \lambda + \frac{\log N}{\sqrt{N}} - D_1 \right) \mathbb{I}_{S \notin S_{sc}} \mathbb{I}_{\sum_{i=1}^{b} S_{i}>\eta + \frac{1}{N}} < 1$ and the average total number of jobs per server is at most $b$.

Based on Lemma 3, we are ready to establish Theorem 1 under JSQ.

$$
\mathbb{E}\left[ \max \left\{ \sum_{i=1}^{b} S_{i} - \eta, 0 \right\} \right] = J_1 + J_2 + J_3 \leq \frac{3b}{N^{1.5} \log N} + \frac{6\mu_{\max}}{\sqrt{N} \log N},
$$

which implies

$$
\mathbb{E}\left[ \max \left\{ \sum_{i=1}^{b} S_{i} - \eta, 0 \right\} \right] \leq \frac{7\mu_{\max}}{\sqrt{N} \log N}.
$$

IV. Extension to Policy Set $\Pi$

In this section, we extend the analysis of JSQ to any policy in $\Pi$. Most steps are the same for a policy in $\Pi$ as for JSQ, except minor differences in proving Lemma 7 and Lemma 9. We next list the places where minor changes are needed.

A. Proof of Lemma 7

In Lemma 7, we consider Lyapunov function in (55)

$$
V(s) = \frac{\lambda}{\mu_1} - s_{1,1}
$$

under the condition $s_1 \leq \lambda + \frac{1+\mu_1+\mu_2}{w_1} \frac{\log N}{\sqrt{N}}$. The drifts of $V(s)$ for JSQ and a policy in $\Pi$ are in the following, respectively.

- For JSQ, the drift in (56) and (57) is

$$
\nabla V(s) = -\lambda \mathbb{I}_{\{S_1<1\}} + \mu_1 s_{1,1} - (1-p)\mu_1 s_{2,1} - \mu_2 s_{2,2}
$$

$$
= -\lambda + \mu_1 s_{1,1} - (1-p)\mu_1 s_{2,1} - \mu_2 s_{2,2}
$$
• For a policy in \( \Pi \), the drift is
\[
\nabla V(s) = -\lambda (1 - A_1(s)) + \mu_1 s_{1,1} - (1 - p)\mu_1 s_{2,1} - \mu_2 s_{2,2}
\]
\[
\leq \frac{1}{\sqrt{N}} - \lambda + \mu_1 s_{1,1} - (1 - p)\mu_1 s_{2,1} - \mu_2 s_{2,2}
\]

Therefore, Lemma 7 still holds for any policy in \( \Pi \).

B. Proof of Lemma 9

In Lemma 9, we consider Lyapunov function in (75)
\[
V(s) = \min \left\{ \lambda + \frac{k \log N}{\sqrt{N}} - s_1, \sum_{i=2}^{b} s_i \right\},
\]
under the condition \( s_1 \leq \lambda + \frac{1 + \mu_1 + \mu_2 \log N}{\sqrt{N}} \). The drifts of \( V(s) \) for JSQ and a policy in \( \Pi \) are in the following, respectively.

• For JSQ,
  - If \( \lambda + \frac{k \log N}{\sqrt{N}} - s_1 \geq \sum_{i=2}^{b} s_i \), the drift in (79) to (80)
    \[
    \nabla V(s) \leq -\lambda \mathbb{I}_{[s_1 = 1]} - (1 - p)\mu_1 s_{2,1} - \mu_2 s_{2,2}
    \]
    \[
    = - (1 - p)\mu_1 s_{2,1} - \mu_2 s_{2,2}
    \]
  - If \( \sum_{i=2}^{b} s_i > \lambda + \frac{k \log N}{\sqrt{N}} - s_1 \), the drift in (85) to (86)
    \[
    \nabla V(s) \leq -\lambda \mathbb{I}_{[s_1 < 1]} + (1 - p)\mu_1 s_{1,1} + \mu_2 s_{1,2} - (1 - p)\mu_1 s_{2,1} - \mu_2 s_{2,2}
    \]
    \[
    = - \lambda + (1 - p)\mu_1 s_{1,1} + \mu_2 s_{1,2} - (1 - p)\mu_1 s_{2,1} - \mu_2 s_{2,2}
    \]

• For any policy in \( \Pi \),
  - If \( \lambda + \frac{k \log N}{\sqrt{N}} - s_1 \geq \sum_{i=2}^{b} s_i \),
    \[
    \nabla V(s) \leq -\lambda (A_1(s) - \mathbb{I}_{[s_i = 1]}) - (1 - p)\mu_1 s_{2,1} - \mu_2 s_{2,2}
    \]
    \[
    \leq \frac{1}{\sqrt{N}} - (1 - p)\mu_1 s_{2,1} - \mu_2 s_{2,2}
    \]
  - If \( \sum_{i=2}^{b} s_i > \lambda + \frac{k \log N}{\sqrt{N}} - s_1 \),
    \[
    \nabla V(s) \leq -\lambda (1 - A_1(s)) + (1 - p)\mu_1 s_{1,1} + \mu_2 s_{1,2} - (1 - p)\mu_1 s_{2,1} - \mu_2 s_{2,2}
    \]
    \[
    \leq \frac{1}{\sqrt{N}} - \lambda + (1 - p)\mu_1 s_{1,1} + \mu_2 s_{1,2} - (1 - p)\mu_1 s_{2,1} - \mu_2 s_{2,2}
    \]

Therefore, Lemma 9 still holds for policies in \( \Pi \).

V. Conclusions

In this paper, we considered load balancing under Coxian-2 service time distribution in heavy traffic regimes. The general Coxian-2 service time distribution does not have DHR and the system considered in this paper lacks monotonicity. We developed an iterative SSC and identified a policy set \( \Pi \), in which any policy can achieve asymptotic zero delay. The set \( \Pi \) includes JSQ, JIQ, I1F and Po2 with \( d = O \left( \frac{\log N}{1 - \lambda} \right) \).

Appendix

A. Proof of Lemma 1

Proof. From the definition of $g$ function in (15), we have

$$g'(x) = \max \left\{ x - \eta, 0 \right\} \cdot \frac{\log N}{\sqrt{N}}.$$

Hence, for any $x \in \left[ \eta - \frac{2}{N}, \eta + \frac{2}{N} \right]$, we have

$$|g'(x)| \leq \frac{|x - \eta|}{\log N \sqrt{N}} \leq \frac{2}{\log N \sqrt{N}} = \frac{2}{\sqrt{N} \log N}.$$

□
B. Proof of Lemma 2

Proof. From the definition of \( g \) function in (15), we have
\[
g'(x) = \max \left\{ \frac{x - \eta}{\sqrt{N}}, 0 \right\}.
\]
For \( x > \eta \), we have
\[
g'(x) = \frac{x - \eta}{\sqrt{N}},
\]
which implies
\[
|g''(x)| = \left| \frac{1}{\frac{\log N}{\sqrt{N}}} \right| = \frac{\sqrt{N}}{\log N}.
\]
\[
\square
\]

C. Proof of Lemma 3

Note \((1 - p)\mu_1 s_{1,1} + \mu_2 s_{1,2} \leq \mu_{\text{max}} s_1 \leq \mu_{\text{max}}\), then we have
\[
J_2 + J_3 \leq \mathbb{E} \left[ \left( g' \left( \sum_{i=1}^{b} S_i \right) \left( -\frac{\log N}{\sqrt{N}} \right) + \lambda |g'(\xi)| + \mu_{\text{max}} |g'(\zeta)| \right) \mathbb{I}_{\sum_{i=1}^{b} s_i \in T_1} \right]
\]
\[
+ \mathbb{E} \left[ \frac{1}{N} \left( \lambda |g''(\eta)| + \mu_{\text{max}} |g''(\zeta)| \right) \mathbb{I}_{\sum_{i=1}^{b} s_i \in T_2} \right]
\]
\[
\leq \frac{4\mu_{\text{max}}}{\sqrt{N} \log N} + \frac{\lambda + \mu_{\text{max}}}{N} \frac{\sqrt{N}}{\log N}
\]
\[
\leq \frac{6\mu_{\text{max}}}{\sqrt{N} \log N}
\]
We consider the following problem
\[
\min_{(s_{1,1}, s_{1,2}) \in S_{\text{ssc1}}} (1 - p)\mu_1 s_{1,1} + \mu_2 s_{1,2},
\]
which is a linear programming in terms of variables \( s_{1,1} \) and \( s_{1,2} \). Therefore, we only need to consider the extreme points of set \( S_{\text{ssc1}} \). In fact, from Fig. 6, it is clear that we only need to consider the following two extreme points.

- Case 1: \( s_{1,1} = \frac{\lambda}{\mu_1} - \frac{\log N}{\sqrt{N}} \) and \( s_{1,2} = \lambda + \left( \frac{1 + \mu_1 + \mu_2}{w_1} - \mu_1 \right) \frac{\log N}{\sqrt{N}} \), where we use the fact \( \frac{1}{\mu_1} + \frac{p}{\mu_2} = 1 \). In this case,
\[
(1 - p)\mu_1 s_{1,1} + \mu_2 s_{1,2} = \lambda + \left( -(1 - p)\mu_1 + \mu_2 \left( \frac{1 + \mu_1 + \mu_2}{w_1} - \mu_1 + 1 \right) \right) \frac{\log N}{\sqrt{N}} \]
\[
\geq \lambda + \left( -(1 - p)\mu_1 + (1 + \mu_1 - \mu_1 \mu_2 + 2\mu_2) \right) \frac{\log N}{\sqrt{N}} \]
\[
= \lambda + \left( 1 + 2\mu_2 \right) \frac{\log N}{\sqrt{N}} \]
\[
\geq \lambda + \frac{\log N}{\sqrt{N}},
\]
where (38) holds because \( w_i = \min\{(1 - p)\mu_1, \mu_2\} \) and (39) holds because \( \frac{1}{\mu_1} + \frac{p}{\mu_2} = 1 \).

- Case 2: \( s_{1,1} = \lambda + \left(1 + \frac{(p + \mu_1 + \mu_2)}{w_i} - \mu_1\right) \log \frac{N}{\sqrt{N}} - s_{1,2} = \frac{\lambda + \left(1 + \frac{\mu_1 + \mu_2}{w_i} - \mu_1\right) \log N}{\sqrt{N}} \) and \( s_{1,2} = \frac{p\lambda}{\mu_2} - \frac{\mu_1 \log N}{\sqrt{N}} \).

At this extreme point, we have

\[
(1 - p)\mu_1 s_{1,1} + \mu_2 s_{1,2} = \lambda + \left(1 - p\right)\mu_1 \left(1 + \frac{\mu_1 + \mu_2}{w_i} - \mu_1\right) \log \frac{N}{\sqrt{N}}
\geq \lambda + \left(1 + \mu_1 + \mu_2 - \mu_1\mu_2\right) \frac{\log N}{\sqrt{N}}
\geq \lambda + \frac{\log N}{\sqrt{N}},
\]

where (42) holds because \( w_i = \min\{(1 - p)\mu_1, \mu_2\} \) and (43) holds because \( \mu_1 + \mu_2 \geq p\mu_1 + \mu_2 = \mu_1\mu_2 \).

Define sets \( \tilde{S}_1 \) and \( \tilde{S}_2 \) such that

\[
\tilde{S}_1 = \left\{ s \left| s_{1,1} \geq \frac{\lambda}{\mu_1} - \frac{\log N}{\sqrt{N}} \text{ and } s_{1,2} \geq \frac{p\lambda}{\mu_2} - \frac{\mu_1 \log N}{\sqrt{N}} \right. \right\}
\]

\[
\tilde{S}_2 = \left\{ s \left| \min \left\{ \eta - s_{1,1}, \sum_{i=2}^{b} s_i \right\} \leq \frac{(c_1 + \mu_1) \log N}{\sqrt{N}} \right. \right\}.
\]

According to the union bound and Lemmas 7-9, we have

\[
\frac{\Pr}\left( S \notin \tilde{S}_1 \cap \tilde{S}_2 \right) \leq \frac{5 \sqrt{N}}{\mu_1 \log N} e^{- \min\left( \frac{\mu_1}{\log \mu_{\text{max}}}, \frac{\mu_2}{\log \mu_{\text{max}}} \right) \log^2 N} + \frac{16}{\mu_1 \mu_2 \log^2 N} e^{- \min\left( \frac{\mu_1}{\log \mu_{\text{max}}}, \frac{\mu_2}{\log \mu_{\text{max}}} \right) \log^2 N}
\]

\[
+ \frac{34}{\mu_1 \mu_2 \log^3 N} e^{- \min\left( \frac{\mu_1}{\log \mu_{\text{max}}}, \frac{\mu_2}{\log \mu_{\text{max}}} \right) \log^2 N}
\]

\[
\leq \frac{3}{N^{0.9}},
\]

where the second inequality holds for a sufficiently large \( N \) such that

\[
\log N \geq \frac{3.5}{\min\left( \frac{\mu_1}{\log \mu_{\text{max}}}, \frac{\mu_2}{\log \mu_{\text{max}}} \right)}.
\]

We note that \( \tilde{S}_1 \cap \tilde{S}_2 \) is a subset of \( S_{\text{ssc}} \). This is because for any \( s \) which satisfies

\[
\min \left\{ \eta - s_{1,1}, \sum_{i=2}^{b} s_i \right\} \leq \frac{(c_1 + \mu_1) \log N}{\sqrt{N}},
\]

we either have

\[
\eta - s_{1,1} \leq \frac{(c_1 + \mu_1) \log N}{\sqrt{N}},
\]

which implies

\[
s_{1,1} \geq \lambda + \left(1 + \frac{\mu_1 + \mu_2}{w_i} - \mu_1\right) \frac{\log N}{\sqrt{N}},
\]
or
\[ \sum_{i=2}^{b} s_i \leq \eta - s_1, \]
which implies
\[ \sum_{i=1}^{b} s_i \leq \eta. \]

Note that
\[ \mathcal{S}_1 \cap \left\{ s \mid s_1 \geq \lambda + \left( \frac{1 + \mu_1 + \mu_2}{w_1} - \mu_1 \right) \frac{\log N}{\sqrt{N}} \right\} = \mathcal{S}_{ssc_1} \]
and
\[ \mathcal{S}_1 \cap \left\{ s \mid \sum_{i=1}^{b} s_i \leq \eta \right\} \subseteq \mathcal{S}_{ssc}. \]

We, therefore, have
\[ \tilde{\mathcal{S}}_1 \cap \tilde{\mathcal{S}}_2 \subseteq \mathcal{S}_{ssc}, \]
and
\[ \mathbb{P}(S \notin \mathcal{S}_{ssc}) \leq \mathbb{P}(S \notin \tilde{\mathcal{S}}_1 \cap \tilde{\mathcal{S}}_2) \leq \frac{3}{N^2}, \]
so Lemma 5 holds.

We next present the iterative SSC approach for proving Lemma 6-Lemma 9. The first three lemmas are on the upper and lower bounds on $S_{1,1}$ and $S_{1,2}$, illustrated in Fig. 8, which shows that both $S_{1,1}$ and $S_{1,2}$ are close to its equilibrium values, in particular, with a high probability, $S_{1,1} \geq \frac{\lambda}{\mu_1} - \frac{\log N}{\sqrt{N}}$ and $S_{1,2} \geq \frac{\mu \lambda}{\mu_2} - \frac{\mu_1 \log N}{\sqrt{N}}$. However, these two low bounds do not guarantee the total departure rate, which is $(1-p)\mu_1 S_{1,1} + \mu_2 S_{1,2}$, is larger than the arrival rate $\lambda$. Therefore, we need Lemma 9 to guarantee sufficient fraction of busy servers $S_1$ such that the total departure rate is "larger than" the arrival rate $\lambda$. We therefore need Lemma 9 to further establish a lower bound on $S_1$ unless the total normalized queue length $\sum_{i=1}^{b} s_i$ is small.

![Fig. 8: Bounds (red lines) on $S_{1,1}$ and $S_{1,2}$](image-url)
D. A tail bound from [15]

To prove the space space collapse results, we first introduce Lemma 10, which will be repeatedly used to obtain probability tail bounds. Lemma 10 allows us to apply Lyapunov-drift-based heavy traffic analysis [4] to reduced state spaces instead of to the entire state space. The lemma is an extension of the tail bound in [2]. This Lyapunov drift analysis on reduced state spaces enables us to iteratively refine the state space at steady state. The lemma was proven in [15]. We include the proof to make the paper self-contained.

Lemma 10. Let \((S(t) : t \geq 0)\) be a continuous-time Markov chain over a finite state space \(S\) and is irreducible, so it has a unique stationary distribution \(\pi\). Consider a Lyapunov function \(V : S \to R^+\) and define the drift of \(V\) at a state \(s \in S\) as

\[
\nabla V(s) = \sum_{s' \in S : s' \neq s} q_{s,s'}(V(s') - V(s)),
\]

where \(q_{s,s'}\) is the transition rate from \(s\) to \(s'\). Assume

\[v_{\text{max}} := \max_{s,s' \in S : q_{s,s'} \geq 0} |V(s') - V(s)| < \infty \text{ and } \bar{q} := \max_{s \in S} (-q_{s,s}) < \infty\]

and define

\[q_{\text{max}} := \max_{s \in S} \sum_{s' \in S : V(s) < V(s')} q_{s,s'} \cdot \]

If there exits a set \(E\) with \(B > 0, \gamma > 0, \delta \geq 0\) such that the following conditions satisfy:

(i) \(\nabla V(s) \leq -\gamma\) when \(V(s) \geq B\) and \(s \in E\).

(ii) \(\nabla V(s) \leq \delta\) when \(V(s) \geq B\) and \(s \notin E\).

Then

\[P(V(S) \geq B + 2v_{\text{max}}j) \leq a^j + \beta P(S \notin E), \quad \forall j \in \mathbb{N},\]

with

\[a = \frac{q_{\text{max}}v_{\text{max}}}{q_{\text{max}}v_{\text{max}} + \gamma} \text{ and } \beta = \frac{\delta}{\gamma} + 1.\]

Proof. Let \(C \geq B - v_{\text{max}}\) and consider Lyapunov function

\[\hat{V}(s) = \max\{C, V(s)\} \cdot \]

At steady state, we have

\[0 = \sum_{V(s) \leq C - v_{\text{max}}} \pi(s) \sum_{s' \neq s} q_{s,s'} (\hat{V}(s') - \hat{V}(s)) + \sum_{C - v_{\text{max}} < V(s) \leq C + v_{\text{max}}} \pi(s) \sum_{s' \neq s} q_{s,s'} (\hat{V}(s') - \hat{V}(s)) + \sum_{V(s) > C + v_{\text{max}}} \pi(s) \sum_{s' \neq s} q_{s,s'} (\hat{V}(s') - \hat{V}(s)). \tag{46}\]

Note \(\nabla \hat{V}(s) = \sum_{s' \neq s} q_{s,s'} (\hat{V}(s') - \hat{V}(s))\). We consider three terms in (46) as follows:

- The first term is 0 because \(V(s) \leq C - v_{\text{max}}\) and \(V(s') \leq C\) imply \(\hat{V}(s) = \hat{V}(s') = C\).
• The second term is bounded

\[
\sum_{C - v_{\text{max}} < V(s) \leq C + v_{\text{max}}} \pi(s) \sum_{s' \neq s} q_{s,s'} (\hat{V}(s') - \hat{V}(s)) \\
\leq \sum_{C - v_{\text{max}} < V(s) \leq C + v_{\text{max}}} \pi(s)q_{\text{max}}v_{\text{max}} \\
\leq q_{\text{max}}v_{\text{max}} (\mathbb{P}(V(S) > C - v_{\text{max}}) - \mathbb{P}(V(S) > C + v_{\text{max}}))
\]

• The third term is divided into two regions \( s \in \mathcal{E} \) and \( s \notin \mathcal{E} \)

\[
\sum_{V(s) > C + v_{\text{max}}} \pi(s) \sum_{s' \neq s} q_{s,s'} (\hat{V}(s') - \hat{V}(s)) = \sum_{V(s) > C + v_{\text{max}}} \pi(s) \sum_{s' \neq s} q_{s,s'} (\hat{V}(s') - \hat{V}(s))
\]

\[
\leq \gamma \mathbb{P}(V(S) > C + v_{\text{max}}, s \in \mathcal{E}) + \delta \mathbb{P}(V(S) > C + v_{\text{max}}, s \notin \mathcal{E})
\]

\[
= - \gamma \mathbb{P}(V(S) > C + v_{\text{max}}) + (\delta + \gamma) \mathbb{P}(V(S) > C + v_{\text{max}}, s \notin \mathcal{E})
\]

where the inequality holds because of two conditions (i) and (ii).

Combine three terms above, we have

\[
(q_{\text{max}}v_{\text{max}} + \gamma)\mathbb{P}(V(S) > C + v_{\text{max}}) \\
\leq q_{\text{max}}v_{\text{max}}\mathbb{P}(V(S) > C - v_{\text{max}}) + (\delta + \gamma)\mathbb{P}(V(S) > C + v_{\text{max}}, S \notin \mathcal{E})
\]

which implies

\[
\mathbb{P}(V(S) > C + v_{\text{max}}) \\
\leq \frac{q_{\text{max}}v_{\text{max}}}{q_{\text{max}}v_{\text{max}} + \gamma} \mathbb{P}(V(S) > C - v_{\text{max}}) + \frac{\delta + \gamma}{q_{\text{max}}v_{\text{max}} + \gamma} \mathbb{P}(V(S) > C + v_{\text{max}}, S \notin \mathcal{E})
\]

\[
= \alpha \mathbb{P}(V(S) > C - v_{\text{max}}) + \kappa \mathbb{P}(S \notin \mathcal{E})
\]

where

\[
\alpha = \frac{q_{\text{max}}v_{\text{max}}}{q_{\text{max}}v_{\text{max}} + \gamma} \quad \text{and} \quad \kappa = \frac{\delta + \gamma}{q_{\text{max}}v_{\text{max}} + \gamma}.
\]

Let \( C = B + (2j - 1)v_{\text{max}}, \forall j \in \mathbb{N} \) and we have

\[
\mathbb{P}(V(S) > B + 2v_{\text{max}}j) \\
\leq \alpha \mathbb{P}(V(S) > B + (j - 1)v_{\text{max}}) + \kappa \mathbb{P}(S \notin \mathcal{E})
\]

(47)

By recursively using the inequality (47), we have

\[
\mathbb{P}(V(S) > B + 2v_{\text{max}}j) \leq \alpha^j + \kappa \mathbb{P}(S \notin \mathcal{E}) \sum_{i=0}^{j} \alpha^i \\
\leq \alpha^j + \frac{\kappa}{1 - \alpha} \mathbb{P}(S \notin \mathcal{E}) \\
= \alpha^j + \beta \mathbb{P}(S \notin \mathcal{E})
\]
As mentioned above, Lemma 10 is an extension of Theorem 1 in [2], where $\mathcal{E} = S^{(N)}$ is the entire state space and $\mathbb{P}(S \notin \mathcal{E}) = 0$. As suggested in Lemma 10, constructing proper Lyapunov functions are critical to establish the tail bounds. In the following lemmas, we construct a sequence of Lyapunov functions and apply Lemma 10 to establish SSC results.

E. Proof of Lemma 6: An upper bound on $S_{1,2}$.

To prove Lemma 6, we first establish a Lyapunov drift analysis for $\mathcal{E} = S^{(N)}$ (the entire state space) in Lemma 11.

**Lemma 11.** Consider Lyapunov function

$$V(s) = s_{1,2} - \frac{p}{\mu_2}.$$  

When $V(s) \geq \frac{\log N}{4\sqrt{N}}$, we have

$$\nabla V(s) \leq -\frac{\mu_1 \mu_2 \log N}{4 \sqrt{N}}.$$

**Proof.** When $V(s) = s_{1,2} - \frac{p}{\mu_2} \geq \frac{\log N}{4\sqrt{N}}$, we have

\begin{align*}
\nabla V(s) &= p\mu_1 s_{1,1} - \mu_2 s_{1,2} \\
&\leq p\mu_1 - (p\mu_1 + \mu_2)s_{1,2} \\
&= \mu_1 (p - \mu_2 s_{1,2}) \leq -\frac{\mu_1 \mu_2 \log N}{4 \sqrt{N}}.
\end{align*}

(48) to (49) holds because $s_{1,1} = s_1 - s_{1,2} \leq 1 - s_{1,2}$; (49) to (50) holds because $\frac{1}{\mu_1} + \frac{p}{\mu_2} = 1$ implies $p\mu_1 + \mu_2 = \mu_1 \mu_2$. □

From Lemma 11, we know $B = \frac{\log N}{4\sqrt{N}}$ and $\gamma = \frac{\mu_1 \mu_2 \log N}{4 \sqrt{N}}$. According to the definition of $q_{\text{max}}$ and $\nu_{\text{max}}$, we have $q_{\text{max}} \leq \mu_{\text{max}} N$ and $\nu_{\text{max}} \leq \frac{1}{N}$. Since $\mathcal{E} = S^{(N)}$ is the entire space, then $\mathbb{P}(S \notin \mathcal{E}) = 0$, we use Lemma 10 (or Theorem 1 in [2]) to obtain the following tail bound with $j = \frac{\sqrt{N} \log N}{8}$,

$$\mathbb{P}(V(S) \geq B + 2\nu_{\text{max}} j) \leq \mathbb{P}\left( S_{1,2} - \frac{p}{\mu_2} \geq \frac{\log N}{2 \sqrt{N}} \right)$$

\begin{align*}
&\leq \left( 1 + \frac{1}{\mu_1 \mu_2 \log N / \sqrt{N}} \right)^{\frac{\sqrt{N} \log N}{8}} \\
&\leq \left( 1 - \frac{\mu_1 \mu_2 \log N / \sqrt{N}}{5 \nu_{\text{max}} \sqrt{N}} \right)^{\frac{\sqrt{N} \log N}{8}} \\
&\leq e^{-\frac{\mu_1 \mu_2 \log^2 N}{40 \nu_{\text{max}}}}
\end{align*}

- (51) holds by substituting $B = \frac{\log N}{4\sqrt{N}}$, $\nu_{\text{max}} = \frac{1}{N}$ and $j = \frac{\sqrt{N} \log N}{8}$;
- (51) to (52) holds based on Lemma 11;
- (52) to (53) holds because $\frac{\mu_1 \mu_2}{\nu_{\text{max}}} \leq \frac{\sqrt{N}}{\log N}$ for a large $N$ satisfying (4).
E. Proof of Lemma 7: A lower bound on $S_{1,1}$.

To prove Lemma 7, we first establish a Lyapunov drift analysis in Lemma 12.

**Lemma 12.** Consider Lyapunov function

$$V(s) = \frac{\lambda}{\mu_1} - s_{1,1}$$

we have

- $\nabla V(s) \leq -\frac{\mu_1 \log N}{3\sqrt{N}}$, when
  $$V(s) \geq \frac{\log N}{2\sqrt{N}} \text{ and } s_{1,2} \leq \frac{p}{\mu_2} + \frac{\log N}{2\sqrt{N}};$$

- $\nabla V(s) \leq 1$, when
  $$V(s) \geq \frac{\log N}{2\sqrt{N}} \text{ and } s_{1,2} \geq \frac{p}{\mu_2} + \frac{\log N}{2\sqrt{N}}.$$

**Proof.** Assuming $s_{1,2} \leq \frac{p}{\mu_2} + \frac{\log N}{2\sqrt{N}}$ and $\frac{\lambda}{\mu_1} - s_{1,1} \geq \frac{\log N}{2\sqrt{N}}$, we have

$$s_1 = s_{11} + s_{12} \leq \frac{p}{\mu_2} + \frac{\lambda}{\mu_1} = 1 - \frac{1}{\mu_1 N} \leq \lambda + \frac{1}{\mu_1 + \mu_2 \log N} \frac{\sqrt{N}}{\mu_1} < 1.$$

Therefore, the drift of $V(s)$ is

$$\nabla V(s) = -\lambda I_{\{s_1 < 1\}} + \mu_1 s_{1,1} - (1 - p) \mu_1 s_{2,1} - \mu_2 s_{2,2}$$

$$\leq -\lambda + \mu_1 s_{1,1} - (1 - p) \mu_1 s_{2,1} - \mu_2 s_{2,2}$$

$$\leq -\lambda + \mu_1 s_{1,1}$$

$$\leq -\frac{\mu_1 \log N}{2\sqrt{N}}$$

$$\leq -\frac{\mu_1 \log N}{3\sqrt{N}},$$

where

- (56) to (57) holds because $I_{\{s_1 < 1\}} = 1$ under JSQ;
- (58) to (59) holds because $s_{1,1} \leq \frac{\lambda}{\mu_1} - \frac{\log N}{2\sqrt{N}}$.

Assuming $s_{1,2} > \frac{p}{\mu_2} + \frac{\log N}{2\sqrt{N}}$ and $s_{1,1} \leq \frac{\lambda}{\mu_1} - \frac{\log N}{2\sqrt{N}}$, we have

$$\nabla V(s) = -\lambda I_{\{s_1 < 1\}} + \mu_1 s_{1,1} - (1 - p) \mu_1 s_{2,1} - \mu_2 s_{2,2} \leq \mu_1 s_{1,1} < 1.$$

Let $E = \left\{ s \mid s \leq \frac{p}{\mu_2} + \frac{\log N}{2\sqrt{N}} \right\}$. we have $V(s) = \frac{\lambda}{\mu_1} - s_{1,1}$ satisfying two conditions:

- $\nabla V(s) \leq -\frac{\mu_1 \log N}{3\sqrt{N}}$ when $V(s) \geq \frac{\log N}{2\sqrt{N}}$ and $s_{1,2} \in E$.
- $\nabla V(s) \leq 1$ when $V(s) \geq \frac{\log N}{2\sqrt{N}}$ and $s_{1,2} \notin E$. 

$\square$
Define $B = \frac{\log N}{2\sqrt{N}}$, $\gamma = \frac{\mu_1 \log N}{3\sqrt{N}}$, and $\delta = 1$. Combining $\eta_{\text{max}} \leq \mu_{\text{max}} N$ and $\nu_{\text{max}} \leq \frac{1}{N}$, we have

$$\alpha \leq \frac{1}{1 + \frac{\mu_1 \log N}{3\sqrt{N}}} \quad \text{and} \quad \beta = \frac{1}{\frac{\mu_1 \log N}{3\sqrt{N}}} + 1.$$  

Based on Lemma 10 with $j = \frac{\sqrt{N} \log N}{4}$, we have

$$\mathbb{P}(V(S) \geq B + 2\nu_{\text{max}}) = \mathbb{P}\left(\frac{\lambda}{\mu_1} - S_{1,1} \geq \log N\right) \geq \frac{\sqrt{N} \log N}{4}\right) + \beta \mathbb{P}(S_{1,2} \notin E) \quad (61)$$

$$\leq \left(1 - \frac{\mu_1 \log N}{4\mu_{\text{max}} \sqrt{N}}\right) + 4\frac{\sqrt{N}}{\mu_1 \log N}e^{-\frac{\mu_1 \mu_2 \log^2 N}{4\mu_{\text{max}}}} \quad (62)$$

$$\leq e^\frac{\mu_1 \log^2 N}{16\mu_{\text{max}}} + 4\frac{\sqrt{N}}{\mu_1 \log N}e^{-\frac{\mu_1 \mu_2 \log^2 N}{4\mu_{\text{max}}}} \quad (63)$$

$$\leq \frac{5}{\mu_1 \log N}e^{-\min\left(\frac{\mu_1}{4\mu_{\text{max}}} \cdot \frac{\mu_1 \mu_2}{4\mu_{\text{max}}} \right) \log^2 N}, \quad (64)$$

where

- (61) holds by substituting $B = \frac{\log N}{2\sqrt{N}}$, $\nu_{\text{max}} \leq \frac{1}{N}$ and $j = \frac{\sqrt{N} \log N}{4}$;
- (61) to (62) holds based on Lemma 12;
- (62) to (63) holds because (i) in the first term in (63), $\frac{\mu_1}{\mu_{\text{max}}} \leq \frac{\sqrt{N}}{\log N}$ for a large $N$ satisfying (4), and (ii) the second term in (62) can be bounded by applying Lemma 6.

G. Proof of Lemma 8: An lower bound on $S_{1,2}$.

**Lemma 13.** Consider Lyapunov function

$$V(s) = \frac{\mu \lambda}{\mu_2} - s_{1,2},$$

we have

- $\nabla V(s) \leq -\frac{\mu_2 \log N}{2\sqrt{N}}$, when

$$V(s) \geq \left(\frac{\mu_1}{\mu_2} + \frac{1}{2}\right) \frac{\log N}{\sqrt{N}} \quad \text{and} \quad s_{1,1} \geq \frac{\lambda}{\mu_1} - \frac{\log N}{\sqrt{N}};$$

- $\nabla V(s) \leq 1$, when

$$V(s) \geq \left(\frac{\mu_1}{\mu_2} + \frac{1}{2}\right) \frac{\log N}{\sqrt{N}} \quad \text{and} \quad s_{1,1} \leq \frac{\lambda}{\mu_1} - \frac{\log N}{\sqrt{N}}.$$
Proof. Assuming \( V(s) = \frac{p\lambda}{\mu_2} - s_{1,2} \geq \left( \frac{p\mu_1}{\mu_2} + \frac{1}{2} \right) \frac{\log N}{\sqrt{N}} \) and \( s_{1,1} \geq \frac{\lambda}{\mu_1} - \frac{\log N}{\sqrt{N}} \), we have
\[
\nabla V(s) = -(p\mu_1 s_{1,1} - \mu_2 s_{1,2}) \leq -\left( p\lambda - \frac{p\mu_1 \log N}{\sqrt{N}} - \mu_2 s_{1,1} \right) \leq -\mu_2 \log N \leq \mu_2 \log N,
\]
where
- (66) to (67) holds because \( s_{1,1} \geq \frac{\lambda}{\mu_1} - \frac{\log N}{\sqrt{N}} \),
- (67) to (68) holds because \( s_{1,2} \leq \frac{p\lambda}{\mu_2} - \left( \frac{p\mu_1}{\mu_2} + \frac{1}{2} \right) \frac{\log N}{\sqrt{N}} \).

Next, assuming \( \frac{p\lambda}{\mu_2} - s_{1,2} \geq \left( \frac{p\mu_1}{\mu_2} + \frac{1}{2} \right) \frac{\log N}{\sqrt{N}} \) and \( s_{1,1} \leq \frac{\lambda}{\mu_1} - \frac{\log N}{\sqrt{N}} \), we have
\[
\nabla V(s) = -(p\mu_1 s_{1,1} - \mu_2 s_{1,2}) \leq \mu_2 s_{1,2} \leq p\lambda \leq 1.
\]

Defining \( \mathcal{E} = \{ s \mid s \geq \frac{\lambda}{\mu_1} - \frac{\log N}{\sqrt{N}} \} \), we have \( V(s) = \frac{p\lambda}{\mu_2} - s_{1,2} \) satisfying two conditions:
- \( \nabla V(s) \leq -\frac{\mu_2 \log N}{\sqrt{N}} \) when \( V(s) \geq \left( \frac{p\mu_1}{\mu_2} + \frac{1}{2} \right) \frac{\log N}{\sqrt{N}} \) and \( s_{1,1} \in \mathcal{E} \).
- \( \nabla V(s) \leq 1 \) when \( V(s) \geq \left( \frac{p\mu_1}{\mu_2} + \frac{1}{2} \right) \frac{\log N}{\sqrt{N}} \) and \( s_{1,1} \notin \mathcal{E} \).

Define \( B = \left( \frac{p\mu_1}{\mu_2} + \frac{1}{2} \right) \frac{\log N}{\sqrt{N}} \), \( \gamma = \frac{\mu_2 \log N}{\sqrt{N}} \) and \( \delta = 1 \). Combining \( q_{\max} \leq \mu_{\max} N \) and \( v_{\max} \leq \frac{1}{N} \), we have
\[
\alpha \leq \frac{1}{1 + \frac{\mu_2 \log N}{\sqrt{N}}} \quad \text{and} \quad \beta = \frac{2}{\mu_2 \log N} + 1.
\]

Based on Lemma 10 with \( j = \frac{\sqrt{N} \log N}{4} \), we have
\[
\mathbb{P} ( V(S) \geq B + 2v_{\max} j) = \mathbb{P} \left( \frac{p\lambda}{\mu_2} - s_{1,2} \geq \left( \frac{p\mu_1}{\mu_2} + 1 \right) \frac{\log N}{\sqrt{N}} \right) \leq \left( \frac{1}{1 + \frac{\mu_2 \log N}{\sqrt{N}}} \right)^{\sqrt{N} \log N} \frac{\sqrt{N} \log N}{4} + \frac{2}{\mu_2 \log N} \mathbb{P} ( S_{1,1} \notin \mathcal{E} ) \leq \left( 1 - \frac{\mu_2 \log N}{3 \mu_{\max} \sqrt{N}} \right) \frac{\sqrt{N} \log N}{4} + \frac{3}{\mu_2 \log N} \mathbb{P} ( S_{1,1} \notin \mathcal{E} ) \leq e^{-\frac{\mu_2 \log N}{12 \mu_{\max} \mu_{\max}^2}} + \frac{15}{\mu_1 \mu_2 \log^2 N} e^{-\min \left( \frac{\mu_1}{\log_{\max} \mu_{\max}}, \frac{\mu_1 \mu_2}{\log_{\max} \mu_{\max}} \right) \log^2 N} \leq \frac{16}{\mu_1 \mu_2 \log^2 N} e^{-\min \left( \frac{\mu_1}{\log_{\max} \mu_{\max}}, \frac{\mu_1 \mu_2}{\log_{\max} \mu_{\max}} \right) \log^2 N} ,
\]
where
- (70) holds by substituting \( B, \nu_{\max} \) and \( j \);
- (70) to (71) holds due to Lemma 13;
(71) to (72) holds because \( \frac{\mu_2}{\mu_{\text{max}}} \leq \sqrt{\frac{N}{\log N}} \) for \( N \) satisfying (4) in the first term of (72);

(72) to (73) holds by Lemma 7 to obtain the tail bound in the second term of (73).

Recall \( \frac{\mu_1}{\mu_2} + 1 = \mu_1 \) and the proof is completed.

H. Proof of Lemma 9: SSC on \( S_1 \) and \( \sum_{i=2}^{b} S_i \).

Define \( L_{1,1} = \frac{\lambda}{\mu_1} - \frac{\log N}{\sqrt{N}} \) and \( L_{1,2} = \frac{\lambda}{\mu_2} - \frac{\mu_1 \log N}{\sqrt{N}} \). Recall \( w_u = \max((1 - p)\mu_1, \mu_2) \), \( w_l = \min((1 - p)\mu_1, \mu_2) \), \( k = \left(1 + \frac{w_u b}{w_l} \right) \left( \frac{1 + \mu_1 + \mu_2}{w_l} + 2\mu_1 \right) \) and \( c_1 = \frac{w_u b}{w_l} \left( \frac{1 + \mu_1 + \mu_2}{w_l} + 2\mu_1 \right) + 2\mu_1 \).

**Lemma 14.** Consider Lyapunov function

\[
V(s) = \min \left\{ \lambda + \frac{k \log N}{\sqrt{N}} - s_1, \sum_{i=2}^{b} s_i \right\}
\]

we have

- \( \nabla V(s) \leq -\frac{w_u \mu_1 \log N}{\sqrt{N}} \), when

\[
V(s) \geq \frac{c_1 \log N}{\sqrt{N}} \quad \text{with} \quad s_{1,1} \geq L_{1,1} \quad \text{and} \quad s_{1,2} \geq L_{1,2};
\]

- \( \nabla V(s) \leq w_u \), when

\[
V(s) \geq \frac{c_1 \log N}{\sqrt{N}} \quad \text{with} \quad s_{1,1} \leq L_{1,1} \quad \text{or} \quad s_{1,2} \leq L_{1,2}.
\]

**Proof.** When \( V(s) \geq \frac{c_1 \log N}{\sqrt{N}} \), the following two inequalities hold

\[
s_1 \leq \lambda + \frac{(k - c_1) \log N}{\sqrt{N}} = \lambda + \frac{1 + \mu_1 + \mu_2 \log N}{w_l} \frac{\mu_1 \log N}{\sqrt{N}},
\]

\[
\sum_{i=2}^{b} s_i \geq \frac{c_1 \log N}{\sqrt{N}}.
\]

We have two observations based on (76) and (77):

- (76) implies \( \mathbb{I}_{\{s_1 < 1\}} = 1 \) under JSQ;

- (77) implies \( s_2 \geq \frac{c_1 \log N}{w_l} \) because \( s_2 \geq s_3 \geq \cdots \geq s_b \), and we have

\[
(1 - p)\mu_1 s_{2,1} + \mu_2 s_{2,2} \geq w_1 s_2 \geq \frac{w_1 c_1 \log N}{b} \frac{\log N}{\sqrt{N}}.
\]

We study the Lyapunov drift and consider two cases:

- Suppose \( \lambda + \frac{k \log N}{\sqrt{N}} - s_1 \geq \sum_{i=2}^{b} s_i \geq \frac{c_1 \log N}{\sqrt{N}} \). In this case, \( V(s) = \sum_{i=2}^{b} s_i \), and

\[
\nabla V(s) \leq \lambda \mathbb{I}_{\{s_1 = 1\}} - (1 - p)\mu_1 s_{2,1} - \mu_2 s_{2,2} \leq - (1 - p)\mu_1 s_{2,1} - \mu_2 s_{2,2} \leq - \frac{w_1 c_1 \log N}{b} \frac{\log N}{\sqrt{N}} \leq - \frac{2w_u \mu_1 \log N}{\sqrt{N}} \leq - \frac{w_u \mu_1 \log N}{\sqrt{N}}.
\]

We have two observations based on (76) and (77):

- Suppose \( \lambda + \frac{k \log N}{\sqrt{N}} - s_1 \geq \sum_{i=2}^{b} s_i \geq \frac{c_1 \log N}{\sqrt{N}} \). In this case, \( V(s) = \sum_{i=2}^{b} s_i \), and

\[
\nabla V(s) \leq \lambda \mathbb{I}_{\{s_1 = 1\}} - (1 - p)\mu_1 s_{2,1} - \mu_2 s_{2,2} \leq - (1 - p)\mu_1 s_{2,1} - \mu_2 s_{2,2} \leq - \frac{w_1 c_1 \log N}{b} \frac{\log N}{\sqrt{N}} \leq - \frac{2w_u \mu_1 \log N}{\sqrt{N}} \leq - \frac{w_u \mu_1 \log N}{\sqrt{N}}.
\]
where
- (79) to (80) holds because $I_{\{s_1=1\}} = 0$ under JSQ;
- (80) to (81) holds because (78);
- (81) to (82) holds because $c_1 \geq \frac{w_u k}{w_i} 2 \mu_1$.

Suppose $\sum_{i=2}^{b} s_i > \lambda + \frac{k \log N}{\sqrt{N}} - s_1 \geq c_1 \log N / \sqrt{N}$. In this case, $V(s) = \lambda + \frac{k \log N}{\sqrt{N}} - s_1$, and

$$
\nabla V(s) \\
\leq - \lambda I_{\{s_1<1\}} + (1 - p) \mu_1 s_{11} + \mu_2 s_{12} - (1 - p) \mu_1 s_{21} - \mu_2 s_{22} \\
\leq - \lambda + w_us_1 - (w_u - (1 - p) \mu_1) s_{11} - (w_u - \mu_2) s_{12} - (1 - p) \mu_1 s_{21} - \mu_2 s_{22} \\
\leq - \lambda + w_u (s_1 - L_{11} - L_{12}) + ((1 - p) \mu_1 L_{11} + \mu_2 L_{12}) - (1 - p) \mu_1 s_{21} - \mu_2 s_{22} \\
= (w_u (k - c_1 + 1 + \mu_1) - (1 - p) \mu_1 - \mu_1 c_2) \frac{\log N}{\sqrt{N}} - (1 - p) \mu_1 s_{21} - \mu_2 s_{22} \\
\leq (w_u (k - c_1 + 1 + \mu_1) - (1 - p) \mu_1 - \mu_1 c_2) \frac{\log N}{\sqrt{N}} - \frac{w_u c_1 \log N}{b} \frac{\log N}{\sqrt{N}} \\
= w_u \left( k - \left(1 + \frac{w_l}{w_u b} \right) c_1 + \mu_1 \right) \frac{\log N}{\sqrt{N}} - (1 - p) \mu_1 - \mu_1 c_2 - w_u \frac{\log N}{\sqrt{N}} \\
\leq w_u \left( k - \left(1 + \frac{w_l}{w_u b} \right) c_1 + \mu_1 \right) \frac{\log N}{\sqrt{N}} \\
\leq - \frac{w_u \mu_1 \log N}{\sqrt{N}},
$$

where
- (85) to (86) holds by adding and substructing $w_us_1 = w_u(s_{11} + s_{12})$;
- (86) to (87) holds because $s_{11}$ and $s_{12}$ taking the lower bounds at $L_{11}$ and $L_{12}$ gives an upper bound;
- (87) to (88) holds by substituting $L_{11} = \frac{\lambda}{\mu_1} - \frac{\log N}{\sqrt{N}}$, $L_{12} = \frac{\lambda}{\mu_2} - \frac{\mu_1 \log N}{\sqrt{N}}$ and $s_1 \leq \lambda + \frac{(k-c_1) \log N}{\sqrt{N}}$. We have $s_1 - L_{11} - L_{12} = (k - c_1 + 1 + \mu_1) \frac{\log N}{\sqrt{N}}$ and $L_{11} + L_{12} = \lambda - ((1 - p) \mu_1 + \mu_1 c_2) \frac{\log N}{\sqrt{N}}$;
- (88) to (89) holds by substituting the lower bound of $(1 - p) \mu_1 s_{21} + \mu_2 s_{22}$ in (78);
- (89) to (90) holds by combining the terms with $c_1$;
- (90) to (91) holds because $(1 - p) \mu_1 + \mu_1 c_2 - w_u = \mu_1 + \mu_2 - w_u \geq 0$;
- (91) to (92) holds because $k - \left(1 + \frac{w_l}{w_u b} \right) c_1 \leq -2 \mu_1$.

Let $\mathcal{E} = \{ s \mid s_{11} \geq L_{11}, s_{12} \geq L_{12} \}$. We have $V(s) = \min \left\{ \lambda + \frac{k \log N}{\sqrt{N}} - s_1, \sum_{i=2}^{b} s_i \right\}$ satisfying the following two conditions based on Lemma 14:

- $\nabla V(s) \leq - \frac{w_u \mu_1 \log N}{\sqrt{N}}$ when $V(s) \geq c_1 \frac{\log N}{\sqrt{N}}$ and $s \in \mathcal{E}$.
- $\nabla V(s) \leq w_u$ when $V(s) \geq c_1 \frac{\log N}{\sqrt{N}}$ and $s \notin \mathcal{E}$.
Define $B = \frac{c_1 \log N}{\sqrt{N}}$, $\gamma = \frac{w_u \mu_1 \log N}{\sqrt{N}}$ and $\delta = w_u$. Combining $q_{\text{max}} \leq \mu_{\text{max}} N$ and $v_{\text{max}} \leq \frac{1}{N}$, we have

$$\alpha \leq \frac{1}{1 + \frac{w_u \mu_1 \log N}{\mu_{\text{max}} \sqrt{N}}}$$

and

$$\beta = \frac{\sqrt{N}}{\mu_1 \log N} + 1.$$ 

Based on Lemma 10 with $j = \frac{\mu_1 \sqrt{N} \log N}{2}$, we have

$$\mathbb{P}(V(S) \geq B + 2v_{\text{max}} j)$$

$$= \mathbb{P}\left(V(S) \geq \frac{c_1 \log N}{\sqrt{N}} + \frac{\mu_1 \log N}{\sqrt{N}}\right)$$

$$\leq \left(1 - \frac{w_u \mu_1 \log N}{\mu_{\text{max}} \sqrt{N}}\right) + \left(\frac{\sqrt{N}}{\mu_1 \log N} + 1\right) \mathbb{P}(s \notin \mathcal{E})$$

$$\leq e^{-\frac{w_u \mu_1 \log^2 N}{4 \mu_{\text{max}}}} + \left(\frac{\sqrt{N}}{\mu_1 \log N} + 1\right) \frac{\mu_{\text{max}}}{\mu_1 \mu_2} - \frac{32}{\mu_1 \mu_2 \log^2 N} e^{-\min\left(\frac{\mu_1}{16 \mu_{\text{max}}}, \frac{\mu_2}{12 \mu_{\text{max}}}, \frac{\mu_1 \mu_2}{40 \mu_{\text{max}}}\right) \log^2 N},$$

where

- (94) holds holds by substituting $B$, $v_{\text{max}}$ and $j$;
- (94) to (95) holds based on Lemma 14;
- (95) to (96) holds $\frac{w_u \mu_1}{\mu_{\text{max}} \sqrt{N}} \leq \frac{\sqrt{N}}{\log N}$ for a large $N$ for the first term in (96);
- (96) to (97) holds by applying the union bound on $\mathbb{P}(S \notin \mathcal{E})$ such that

$$\mathbb{P}(s \notin \mathcal{E}) \leq \mathbb{P}(s_{1,1} < L_{1,1}) + \mathbb{P}(s_{1,2} < L_{1,2})$$

$$\leq \frac{32}{\mu_1 \mu_2 \log^2 N} e^{-\min\left(\frac{\mu_1}{16 \mu_{\text{max}}}, \frac{\mu_2}{12 \mu_{\text{max}}}, \frac{\mu_1 \mu_2}{40 \mu_{\text{max}}}\right) \log^2 N}.$$

Under JSQ, a job is discarded or blocked only if all buffers are full, i.e. when $N \sum_{i=1}^b S_i = Nb$. From Theorem 1, we have

$$\mathbb{P}(B) = \mathbb{P}\left(N \sum_{i=1}^b S_i = Nb\right) = \mathbb{P}\left(\sum_{i=1}^b S_i \geq b\right)$$

$$\leq \mathbb{P}\left(\max\left\{\sum_{i=1}^b S_i - \lambda - \frac{k \log N}{\sqrt{N}}, 0\right\} \geq b - \lambda - \frac{k \log N}{\sqrt{N}}\right)$$

$$\leq \frac{8 \mu_{\text{max}}}{b - \lambda \sqrt{N \log N}}.$$
where (100) to (101) holds due to the Markov inequality; and (101) to (102) holds because of Theorem 1 and \( b - \lambda \geq \frac{8k \log N}{\sqrt{N}} \).

For jobs that are not discarded, the average queueing delay according to Little’s law is

\[
\mathbb{E} \left[ \sum_{i=1}^{b} S_i \right] = \frac{\mathbb{E} \left[ \sum_{i=1}^{b} S_i \right]}{\lambda(1 - \mathbb{P}(B))}.
\]

Therefore, the average waiting time is

\[
\mathbb{E}[\mathcal{W}] = \frac{\mathbb{E} \left[ \sum_{i=1}^{b} S_i \right]}{\lambda(1 - \mathbb{P}(B))} - 1
\]

\[
\leq \frac{k \log N}{\sqrt{N}} + \frac{7\mu_{\text{max}}}{\sqrt{N \log N}} + \frac{\lambda \mathbb{P}(B)}{\lambda(1 - \mathbb{P}(B))}
\]

\[
\leq \frac{2k \log N}{\sqrt{N}} + \frac{14\mu_{\text{max}} + \frac{16\mu_{\text{max}}}{b - \lambda}}{\sqrt{N \log N}},
\]

where the last inequality holds because \( \lambda(1 - \mathbb{P}(B)) \geq 0.5 \) under \( b - \lambda \geq \frac{8k \log N}{\sqrt{N}} \).

Next, we study the waiting probability \( \mathbb{P}(\mathcal{W}) \). Define \( \overline{\mathcal{W}} \) to be the event that a job entered into the system (not blocked) and waited in the buffer and \( \mathbb{P}(\overline{\mathcal{W}}) \) is the steady-state probability of \( \overline{\mathcal{W}} \). Applying Little’s law to the jobs waiting in the buffer,

\[
\lambda \mathbb{P}(\overline{\mathcal{W}}) \mathbb{E}[T_Q] = \mathbb{E} \left[ \sum_{i=2}^{b} S_i \right],
\]

where \( T_Q \) is the waiting time for the jobs waiting in the buffer. Since \( \mathbb{E}[T_Q] \) is lower bounded by \( T_Q = \min \left\{ \frac{1}{\mu_1}, \frac{1}{\mu_2} \right\} \), we have

\[
\mathbb{P}(\overline{\mathcal{W}}) \leq \frac{\mathbb{E} \left[ \sum_{i=2}^{b} S_i \right]}{\lambda T_Q}.
\]

We now provide a bound on \( \mathbb{E} \left[ \sum_{i=2}^{b} S_i \right] \). From the work-conserving law, we have

\[
\mathbb{E}[S_1] = \lambda(1 - \mathbb{P}(B)) \geq \lambda \left( 1 - \frac{8\mu_{\text{max}}}{b - \lambda} \frac{1}{\sqrt{N \log N}} \right).
\]

Therefore, we have

\[
\mathbb{E}[S_1] \geq \lambda - \frac{8\mu_{\text{max}}}{b - \lambda} \frac{1}{\sqrt{N \log N}}.
\]

From Theorem 1, one has

\[
\mathbb{E} \left[ \sum_{i=1}^{b} S_i \right] \leq \lambda + \frac{k \log N}{\sqrt{N}} + \frac{7\mu_{\text{max}}}{\sqrt{N \log N}}.
\]
The above two inequalities give the following bound on $E \left[ \sum_{i=2}^{b} S_i \right]$: 

$$E \left[ \sum_{i=2}^{b} S_i \right] \leq \frac{k \log N}{\sqrt{N}} + \frac{7 \mu_{\text{max}} + \frac{8 \mu_{\text{max}}}{b-\lambda}}{\sqrt{N \log N}}.$$ 

Finally, a job not routed to an idle server is either blocked or waited in the buffer 

$$P(W) = P(B_N) + P(W) \leq P(B) + \frac{E \left[ \sum_{i=2}^{b} S_i \right]}{\lambda T_Q} \leq \frac{1}{\lambda T_Q} \frac{k \log N}{\sqrt{N}} + \frac{1}{\lambda T_Q} \frac{7 \mu_{\text{max}} + \frac{8 \mu_{\text{max}}}{b-\lambda}}{\sqrt{N \log N}}.$$ 

The analysis for PoJo is similar, except that 

$$P(B) = P \left( B \left| S_b \leq 1 - \frac{1}{\mu_1 N^a} \right. \right) P \left( S_b \leq 1 - \frac{1}{\mu_1 N^a} \right) \quad (103)$$

$$+ P \left( B \left| S_b \geq 1 - \frac{1}{\mu_1 N^a} \right. \right) P \left( S_b > 1 - \frac{1}{\mu_1 N^a} \right) \quad (104)$$

$$\leq P \left( B \left| S_b \leq 1 - \frac{1}{\mu_1 N^a} \right. \right) + P \left( S_b > 1 - \frac{1}{\mu_1 N^a} \right) \quad (105)$$

$$\leq \left( 1 - \frac{1}{\mu_1 N^a} \right) \frac{\mu_1 N^a \log N}{\lambda T_Q} + P \left( \sum_{i=1}^{b} S_i > b - \frac{b}{\mu_1 N^a} \right) \quad (106)$$

$$\leq \frac{1}{N} + \frac{E \left[ \max \left\{ \sum_{i=1}^{b} S_i - \lambda - \frac{k \log N}{\sqrt{N}}, 0 \right\} \right]}{b - \lambda} \quad (107)$$

$$\leq \frac{1}{N} + \frac{8 \mu_{\text{max}}}{b-\lambda} \frac{1}{\sqrt{N \log N}} \quad (108)$$

(105) to (106) holds because it denotes the probability of the event all sampled $d$ servers have $b$ jobs; (106) to (107) holds because $(1 - \frac{1}{x})^x \leq \frac{1}{e}$ for $x \geq 1$ and the Markov inequality; (107) to (108) holds because of Theorem 1 and $b - \lambda \geq \frac{8k \log N}{\sqrt{N}} + \frac{8b}{\mu_1 N^a}$. The remaining analysis is the same.

Finally, for JIQ and I1F, we have not been able to bound $P(B)$. However, 

$$P(W) = P(S_1 = 1) \leq P \left( \sum_{i=1}^{b} S_i \geq 1 \right)$$

$$\leq P \left( \max \left\{ \sum_{i=1}^{b} S_i - \lambda - \frac{k \log N}{\sqrt{N}} \right\} \geq \frac{1}{N^a} - \frac{k \log N}{\sqrt{N}} \right).$$

The result follows from the Markov inequality.
