Objectives: AmpC β-lactamases are classified as Amber Class C and Bush Group 1. AmpC β-lactamases can hydrolyze broad and extended-spectrum cephalosporins, and are not inhibited by β-lactamase inhibitors such as clavulanic acid. This study was conducted to identify DHA-23, a novel plasmid-mediated and inducible AmpC β-lactamase obtained from Enterobacteriaceae.

Methods: A total of 210 carbapenem-resistant Enterobacteriaceae isolates were collected from a medical center (comprising two branches) in Northern Taiwan during 2009–2012. AmpC β-lactamase genes were analyzed through a polymerase chain reaction using plasmid DNA templates and gene sequencing. The genetic relationships of the isolates were typed using pulsed-field gel electrophoresis following the digestion of intact genomic DNA by using XbaI.

Results: Three enterobacterial isolates (one Escherichia coli and two Klebsiella pneumoniae) were obtained from three hospitalized patients. All three isolates were resistant or intermediately susceptible to all β-lactams, and exhibited reduced susceptibility to carbapenems. These three isolates expressed a novel AmpC β-lactamase, designated DHA-23, approved by the curators of the Lahey website. DHA-23 differs from DHA-1 and DHA-6 by one amino acid substitution (Ser245Ala), exhibiting three amino acid changes compared with DHA-7 and DHA-Morganella morganii; three amino acid changes compared with DHA-3; four amino acid changes compared with DHA-5; and eight amino acid changes compared with DHA-2 (>97% identity). This AmpC β-lactamase is inducible using a system involving ampR.

Conclusion: This is the first report to address DHA-23, a novel AmpC β-lactamase. DHA-type β-lactamases are continuous threat in Taiwan.

Keywords: AmpC beta-lactamase, Enterobacteriaceae, antimicrobial resistance epidemiology
Introduction

AmpC enzymes are located in the bacterial periplasm, with the exception of the AmpC β-lactamase of *Psychrobacter immobili*is, which is secreted mainly into the external medium (Feller et al., 1997). They are active on cephalosporins, cephemycins (such as cefoxitin), oxyiminocephalosporins (such as cefazidime and cefotaxime), and monobactams (such as aztreonam). AmpC β-lactamases are classified according to their Amber molecular structure as belonging to Class C, whereas according to function, they are classified into Group 1 (Bush and Jacoby, 2010). The sequence of the ampC gene differed from the sequence of penicillinase-type β-lactamases such as TEM-1 but similarly, had serine at its active site (Knott-Hunziker et al., 1982). AmpC β-lactamases, in contrast to extended-spectrum β-lactamases (ESBLs), can hydrolyze broad and extended-spectrum cephemycins, and are not inhibited by β-lactamase inhibitors such as clavulanic acid. AmpC β-lactamases are assumed to be chromosomally mediated; however, *Klebsiella pneumoniae*, *K. oxytoca*, *Proteus mirabilis*, and *Salmonella* sp. lack a chromosomal blu_Ampc gene (Bergstrom et al., 1983; Bauerfeind et al., 1989). Described plasmid-mediated AmpC genes in a *K. pneumoniae* isolate from South Korea. There are various types of plasmid-mediated AmpC β-lactamases: CMY, MIR, MOX, LAT, FOX, DHA, ACT, ACC, and CFE (Jacoby, 2009). AmpR is a member of the LysR transcriptional regulator family. During normal growth, in the absence of β-lactam as an inducer, the AmpR regulator binds with a peptidoglycan precursor uridine pyrophosphoryl-N-acetyl muramylyl-L-alanyl-D-glutamylmeso-diaminopimelic acid-D-alanyl-D-alanine (UDP-N-acetylmuramic acid peptide). AmpR- UDP-N-acetylmuramic acid peptide complex binds to the operator site between the ampC and ampR structural genes, leading to the repression of ampC expression. Displacement of the UDP-N-acetylmuramic acid peptides signals a conformational change in AmpR, which activates the transcription of ampC. AmpR mutations are less common but can also result in high-constitutive or hyperinducible phenotypes (Kaneko et al., 2005). Resistance caused by plasmid-mediated AmpC β-lactamase is less common than the production of ESBLs, but may be more difficult to detect. The purpose of this study was to identify DHA-23, a novel plasmid-mediated and inducible AmpC β-lactamase identified in clinical enterobacterial isolates that were obtained from a hospital in Northern Taiwan.

Materials and Methods

Isolates and Data Collection

A total of 210 carbapenem-resistant Enterobacteriaceae isolates were collected from a medical center (comprising two branches) in Northern Taiwan from 2009 to 2012, including 100 *K. pneumoniae*, 53 *Escherichia coli*, 41 *Enterobacter cloacae*, and 16 other isolates (one *K. oxytoca*, one *Citrobacter freundii*, two *Providencia retigera*, eight *Serratia* sp., and four *E. aerogenes*). The isolates were identified using the VITEK system (bioMérieux Vitek Systems Inc., Hazelwood, MO, USA).

Polymrase Chain Reaction Detection of Carbapenemase Genes and Insertion Sequences

The carbapenemase-encoding genes were detected using polymerase chain reaction (PCR) methods as previously suggested by Woodford et al. (2006) and Ellington et al. (2007). All primers used in this study, such as bla_TEM-type, bla_SHV-type, blaCTX-M-type, blaCMY-type, and blaDHA-type primers, were described previously (Tenover et al., 1995; Chung et al., 2011; Qi et al., 2011; Huang et al., 2012). Sequence similarity searches were conducted using the BLAST program.

Pulsed-Field Gel Electrophoresis

The isolates were compared using pulsed-field gel electrophoresis (PFGE; Seifert et al., 2005) following the digestion of intact genomic DNA by using XbaI (Biolabs, UK). The XbaI restriction profiles were initially compared using visual inspection according to the criteria of Tenover et al. (1995). A computer-assisted analysis was performed using BioNumerics (Applied Maths, Sint-Martens-Latem, Belgium) software.

FIGURE 1 | Alignment of the deduced amino-acid sequences of DHA-23 with those of other DHA type AmpC enzymes. Identical amino-acids are marked with dashes. The underlined amino-acids are those that may be involved in the catalytic site of these AmpC enzymes, including the β-lactamase active site S–V–S–K and the conserved triad K–T–G. DHA-MM, DHA-Morganella morganii.
conjugation experiments were performed using *E. coli* DH5α as the recipient (Poirel et al., 1999b). Transconjugants were selected on Luria–Bertani agar plates supplemented with sodium azide (100 mg/L) and cefotaxime (2 mg/L). In addition, cefoxitin (8 mg/L) was added to prevent the selection of ESBL-producing transconjugants. Electrotransformants were selected on agar containing cefotaxime (2 mg/L) or cefoxitin (8 mg/L).

**Results**

**Novel AmpC β-Lactamase Discovered in Three Enterobacterial Isolates**

One *E. coli* (EC56) and two *K. pneumoniae* (KP11 and KP19) isolates that exhibited resistance to cefoxitin, cefotaxime, and ceftazidime were isolated from 3 adult patients hospitalized in Northern Taiwan (Table 1). We had the designated DHA-23 approved by the curators of the Lahey website2. Using specific primers for *blaDHA*−1, we obtained PCR fragments from plasmid DNA preparations of *E. coli* EC56 and *K. pneumoniae* KP11 and KP19. The deduced amino-acid sequence (Figure 1) indicated that DHA-23 exhibited only one amino-acid change compared with DHA-1 and DHA-6 (Ser245Ala), two amino acid changes compared with DHA-7 and DHA-

**ampR Gene Found Immediately Upstream from the ampC Gene**

The 110-bp intercistronic region of *ampC* and *ampR* contained the promoter sequences for *ampC* and *ampR* expression. This region of *blaDHA−23* was identical to the corresponding region of...

Clavulanic Acid Acts as An Inducer of DHA-23

E. coli EC56 contained 4 β-lactamases that corresponded to TEM-1, CTX-M-14, CMY-2, and DHA-23. K. pneumoniae KP11 and KP19 both contained β-lactamases that corresponded to TEM-1, SHV-11, CTX-M-14, and DHA-23. The genotyping of isolates was conducted using PFGE by using XbaI digestion. The results indicated that these two K. pneumoniae isolates had similar pulsotypes. Conjugation experiments were subsequently conducted, regardless of whether cefoxitin was used as a selecting agent, and the transfer of a plasmid coding the DHA-23 cephalosporinase into E. coli DH5α was not observed. The data suggested that the blaDHA-23 plasmid is not self-transferable. Electroporation experiments were then performed using plasmid DNA preparation of E. coli EC56 and K. pneumoniae KP11 and KP19. Amplification and gene sequencing were used to analyze the plasmid DNA, and the results revealed that the E. coli DH5α (pEC56) transformants contained two β-lactamases, TEM-1 and DHA-23. The E. coli DH5α (pKP11) and E. coli DH5α (pKP19) transformants contained only one β-lactamase, TEM-1. However, repeated electrotransformation experiments failed to obtain transformants carrying DHA-23 from KP11 and KP19. The MIC of ceftazidime (128 mg/L) for E. coli EC56 was not reduced by clavulanic acid. However, the MICs of cefotaxime (0.12 mg/L) and ceftazidime (1.0 mg/L) for E. coli DH5α (pEC56) increased in the presence of clavulanic acid, suggesting that clavulanic acid may act as an inducer of DHA-23 (Table 2).

Discussion

This study presented a novel plasmid-mediated and inducible AmpC β-lactamase obtained from Enterobacteriaceae, designated DHA-23 and approved by the curators of the Lahey website. There are currently 22 DHA variants listed on the site, most of which are assigned with no reference to the sequence.

In Table 1, MICs of the DHA-23 carrying enterobacterial isolates E. coli EC56 and K. pneumoniae KP11 and KP19 to antimicrobial agents show that cephemycins (such as cefoxitin) are not hydrolyzed by ESBLs, but are hydrolyzed by associated AmpC β-lactamase. Class-C enzymes hydrolyze cephemycins but do not hydrolyze extended-spectrum cephalosporins effectively. DHA-23 showed that the MICs did not substantially increase for cefotaxime and ceftazidime when DHA-23 was present in the transformants, whereas the MICs of cefoxitin increased to 32 mg/L (Table 2). Resistance to the carbapenem was variable. All strains were fully susceptible to meropenem and doripenem (Table 2). In general,
carbapenems are regarded as the preferred agent for treatment. However, the production of AmpC β-lactamase significantly increased the MICs of carbapenems was reported by Bradford et al. with the ACT-1 β-lactamase (Bradford et al., 1997), and by Lee et al. (2010) with the DHA-1 β-lactamase. Based on the recombinant experiments, Martinez-Martinez et al. (1999) demonstrated that MICs of carbapenems increased significantly in the recombinant K. pneumoniae strain harboring over expressing AmpC. They proposed that the spread of strains that express the plasmid-mediated AmpC β-lactamases and lack porins may create serious therapeutic problems in the future. Furthermore, proteomic investigation of the inner-membrane fraction of carbapenem-resistant strain of Acinetobacter baumannii supported a model for the importance of upregulated AmpC β-lactamases and down-regulated OmpW production in the mediation of carbapenem resistance in A. baumannii (Tiwari et al., 2012).

Enterobacteriaceae isolates producing a DHA-1-like enzyme have been identified previously in Taiwan (Yan et al., 2002; Yu et al., 2004; Wu et al., 2005). We report that DHA-type β-lactamases remain a threat in this country. Further nationwide surveillance should be conducted, antibiotic stewardship should be advocated, and strict infection control measures should be enforced.

Acknowledgments

The present study was supported by a research grant (TMU99-AE1-B02) from Taipei Medical University, Taiwan, and (MMH-10144) from Mackay Memorial Hospital, Taiwan.
