Is extreme learning machine feasible? A theoretical assessment (Part II)

Shaobo Lin, Xia Liu, Jian Fang, and Zongben Xu

Abstract—An extreme learning machine (ELM) can be regarded as a two stage feed-forward neural network (FNN) learning system which randomly assigns the connections with and within hidden neurons in the first stage and tunes the connections with output neurons in the second stage. Therefore, ELM training is essentially a linear learning problem, which significantly reduces the computational burden. Numerous applications show that such a computation burden reduction does not degrade the generalization capability. It has, however, been open that whether this is true in theory. The aim of our work is to study the theoretical feasibility of ELM by analyzing the pros and cons of ELM. In the previous part on this topic, we pointed out that via appropriate selection of the activation function, ELM does not degrade the generalization capability in the expectation sense. In this paper, we launch the study in a different direction and show that the randomness of ELM also leads to certain negative consequences. On one hand, we find that the randomness causes an additional uncertainty problem of ELM, both in approximation and learning. On the other hand, we theoretically justify that there also exists an activation function such that the corresponding ELM degrades the generalization capability. In particular, we prove that the generalization capability of ELM with Gaussian kernel is essentially worse than that of FNN with Gaussian kernel. To facilitate the use of ELM, we also provide a remedy to such a degradation. We find that the well-developed coefficient regularization technique can essentially improve the generalization capability. The obtained results reveal the essential characteristic of ELM and give theoretical guidance concerning how to use ELM.

Index Terms—Extreme learning machine, neural networks, generalization capability, Gaussian kernel.

I. INTRODUCTION

An extreme learning machine (ELM) is a feed-forward neural network (FNN) like learning system whose connections with output neurons are adjustable, while the connections with and within hidden neurons are randomly fixed. ELM then transforms the training of a FNN into a linear problem in which only connections with output neurons need adjusting. Thus the well-known generalized inverse technique [22], [23] can be directly applied for the solution. Due to the fast implementation, ELM has been widely used in regression [10], classification [14], fast object recognition [32], illuminance prediction [27], mill load prediction [28], face recognition [21], and so on.

Compared with the enormous emergences of applications, the theoretical feasibility of ELM is, however, almost vacuum. Up till now, only the universal approximation property of ELM is analyzed [10]–[12], [33]. It is obvious that one of the main reasons of the low computational burden of ELM is that only a few neurons are utilized to synthesize the estimator. Without such an attribution, ELM can not outperform other learning strategies in implementation. For example, as a special case of ELM, learning in the sample-dependent hypothesis space (the number of neurons equals to the number of sample) [27], [29], [30] can not essentially reduce the computational complexity. Thus, the universal approximation property of ELM is too weak and can not capture the essential characteristics of ELM. Therefore, the generalization capability and approximation property of ELM should be investigated. The former one focuses on the relationship between the prediction accuracy and the number of samples, while the latter one discusses the dependency between the prediction accuracy and the number of hidden neurons.

The aim of our study is to theoretically verify the feasibility of ELM by analyzing the pros and cons of ELM. In the first part on this topic [18], we casted the analysis of ELM into the framework of statistical learning theory and concluded that with appropriately selected activation functions (polynomial, Nadaraya-Watson and sigmoid), ELM did not degrade the generalization capability in the expectation sense. This means that, ELM reduces the computation burden without sacrificing the prediction accuracy by selecting appropriate activation function, which can be regarded as the main advantage of ELM. To give a comprehensive feasibility analysis of ELM, we should also study the disadvantage of ELM and, consequently, reveal the essential characteristics of ELM.

Compared with the classical FNN learning [9], our study in this paper shows that there are mainly two disadvantages of ELM. One is that the randomness of ELM causes an additional uncertainty problem, both in approximation and learning. The other is that there also exists a generalization degradation phenomenon for ELM with inappropriate activation function. The uncertainty problem of ELM means that there exists an uncertainty phenomenon between the small approximation error (or generalization error) and high confidence of ELM estimator. As a result, it is difficult to judge whether a single time trail of ELM succeeds or not. Concerning the generalization degradation phenomenon, we find that, with the widely used Gaussian-type activation function (or Gaussian kernel for the sake of brevity), ELM degrades the generalization capability of FNN.

To facilitate the use of ELM, we provide certain remedies to circumvent the aforementioned drawbacks. On one hand, we find that multiple times training can overcome the uncertainty problem of ELM. On the other hand, we show that, by adding
neurons and implementing $l^2$ coefficient regularization simultaneously, the generalization degradation phenomenon of ELM can be avoided. In particular, using $l^2$ coefficient regularization to determine the connections with output neurons, ELM with Gaussian kernel can reach the almost optimal learning rate of FNN in the expectation sense, provided the regularization parameter is appropriately tuned.

The study of this paper together with the conclusions in [13] provides a comprehensive feasibility analysis of ELM. To be detail, the performance of ELM depends heavily on the activation function and the random assignment mechanism. With appropriately selected activation function and random mechanism, ELM does not degrade the generalization capability of FNN learning in the expectation sense. However, there also exist some activation functions, with which ELM degrades the generalization capability for arbitrary random mechanism. Moreover, due to the randomness, ELM suffers from an uncertainty problem, both in approximation and learning. Our study also shows that both the uncertain problem and degradation phenomenon are remediable. All these results lay a solid fundamental for ELM and give a guidance of how to use ELM more efficiently.

The rest of the paper is organized as follows. After giving a fast review of ELM, we present an uncertainty problem of ELM approximation in the next section. In Section 3, we first introduce the main conception of statistical learning theory and then study the generalization capability of ELM with Gaussian kernel. We find that the deduced generalization error bound is larger than that of FNN with Gaussian kernel. This means that ELM with Gaussian kernel may degrade the generalization capability. In Section 4, we provide a remedy to such a degradation. Using the empirical covering number technique, we prove that implementing $l_2$ coefficient regularization can essentially improve the generalization capability of ELM with Gaussian kernel. In Section 5, we give proofs of the main results. We conclude the paper in the final section with some useful remarks.

II. AN UNCERTAINTY PROBLEM OF ELM APPROXIMATION

A. Extreme learning machine

The extreme learning machine (ELM), introduced by Huang et al. [11] can be regarded as a two stage FNN learning system which randomly assigns the connections with and within hidden neurons in the first stage and tunes the connections with output neurons in the second stage. Since then, various variants of ELM such as evolutionary ELM [15], Bayesian ELM [25], incremental ELM [13], and regularized ELM [3] were proposed. We refer the readers to a fruitful survey [15] for more information about ELM.

As a two stage learning scheme, ELM comprises a choice of hypothesis space, and a selection of optimization strategy (or learning algorithm) in the first and second stages, respectively. To be precise, in the first stage, ELM picks hidden parameters with and within the hidden neurons randomly to build up the hypothesis space. This makes the hypothesis space of ELM form as

$$\mathcal{H}_{\phi, n} = \left\{ \sum_{j=1}^{n} a_j \phi(w_j, x) : a_j \in \mathbb{R} \right\},$$

where $w_j$’s are drawn independently and identically (i.i.d.) according to a specified distribution $\mu$. It is easy to see that the hypothesis space of ELM is essentially a linear space. In the second stage, ELM tunes the output weights by using the well developed linear optimization technique. In this paper, we study the generalization capability of the classical ELM [10] rather than its variants. That is, the linear optimization technique employed in the second stage of ELM is the least square:

$$f_{x, \phi, n} = \arg \min_{f \in \mathcal{H}_{\phi, n}} \sum_{i=1}^{m} |f(x_i) - y_i|^2,$$

where $(x_i, y_i)_{i=1}^{m}$ are the given samples.

B. An uncertainty problem for ELM approximation

The randomness of ELM leads to a reduction of computational burden. However, there also exists a certain defect caused by the randomness. The main purpose of this section is to quantify such a defect by studying the approximation capability of ELM with Gaussian kernel.

For this purpose, we introduce a quantity called the modulus of smoothness [4] to measure the approximation capability. For this purpose, we introduce a quantity called the modulus of smoothness [4] on $A \subseteq \mathbb{R}^d$ is defined by

$$\omega_{r,A}(f, t) = \sup_{|h| \leq t} \| \Delta_h f \|_A,$$

where $\cdot$ denotes the Euclidean norm, $\| \cdot \|_A$ denotes the uniform norm on $C(A)$, and the $r$-th difference $\Delta_h f(x, \cdot)$ is defined by

$$\Delta_h f(x, \cdot) = \left\{ \frac{1}{r!} \sum_{j=0}^{r} (-1)^{r-j} f(x + jh) \right\}_{j=0}^{r}$$

for $h = (h_1, \ldots, h_d) \in \mathbb{A}^d$ and $A_{r,h} := \{x \in A : x + sh \in A\}$, for all $s \in [0, r]$. It is well known [4] that

$$\omega_{r,A}(f, u) \leq (1 + \frac{1}{u})^r \omega_{r,A}(f, u)$$

for all $f \in C(A)$ and all $u > 0$.

Let $s \in \mathbb{N}$, we focus on the following Gaussian-type activation function (or Gaussian kernel),

$$K_{\sigma,s}(t) = \sum_{j=1}^{s} \left( \begin{array}{c} s \\ j \end{array} \right) (-1)^{s-j} \frac{1}{j^s} \left( \frac{2}{\sigma^2} \right)^{\frac{d}{2}} \exp \left\{ -\frac{t^2}{2\sigma^2} \right\}.$$

Then, the corresponding ELM estimator is defined by

$$f_{x, \sigma, s, n} = \arg \min_{f \in \mathcal{H}_{s, \sigma, n}} \sum_{i=1}^{m} |f(x_i) - y_i|^2,$$

where

$$\mathcal{H}_{\sigma, s, n} = \left\{ \sum_{j=1}^{n} a_j K_{\sigma, s}(\theta_j, x) : x \in \mathbb{R}^d \right\},$$

for all $f \in C(A)$ and all $u > 0$.
\( K_{\sigma,s}(\theta_j, x) := K_{\sigma,s}(\{\theta_j - x\}^2) := K_{\sigma,s}(\{\theta_j - x\}^2) \),

\[ I^d := [0, 1]^d \text{ and } \{\theta_j\}_{j=1}^n \text{ are drawn i.i.d. according to arbitrary fixed distribution } \mu \text{ on the interval } [-a, 1+a]^d \text{ with } a > 0. \]

The following Theorem 1 shows that there exists an uncertainty problem of ELM approximation.

**Theorem 1:** Let \( d, s, n \in \mathbb{N} \). If \( f \in C(I^d) \), then with confidence at least \( 1 - 2 \exp\{-cn^2d^4\} \) (with respect to \( \mu^n \)), there holds

\[ \inf_{g_n \in \mathcal{H}_{s,n}} \|f - g_n\|_{I^d} \leq C (\omega_{s,l^d}(f, \sigma) + \|f\|_{l^d} \sigma^d), \]

where \( C \) is a constant depending only on \( d \) and \( r \).

It follows from Theorem 1 that the approximation capability of ELM with Gaussian kernel depends on the kernel parameters, \( s, \sigma \), and the number of hidden neurons, \( n \). Furthermore, Theorem 1 shows that, compared with the classical FNN approximation, there exists an additional uncertainty problem of ELM approximation. That is, both the approximation error and the confidence monotonically increase with respect to \( \sigma \). Therefore, it is impossible to deduce a small approximation error with extremely high confidence. In other words, it is difficult to judge whether the approximation error of ELM is smaller than arbitrary specified approximation accuracy, which does not appear in the classical Gaussian-FNN approximation.

We find further in Theorem 1 that the best choice of the kernel parameter, \( \sigma \), is a trade-off between the confidence and the approximation error. An advisable way to determine \( \sigma \) is to set \( \sigma^d = n^{-1} \) for arbitrary small \( \varepsilon \in \mathbb{R}_+ \). Under this circumstance, we can deduce that the approximation error of \( \mathcal{H}_{s,n} \) asymptotically equals to \( \omega_{s,l^d}(f, n^{-1+\varepsilon}d^2) + n^{1+\varepsilon}/2 \) with confidence at least \( 1 - 2 \exp\{-cn^2\} \). Finally, we should verify the optimality of the above approximation bound and therefore justify the optimality of the selected \( \sigma \). To this end, we introduce the set of \( r \)-smooth functions.

Let \( u \in \mathbb{N}_0 \) be a function that one uses to model the correspondence between \( X \) and \( Y \), as induced by \( \rho \). One natural measurement of the error incurred by \( f \) of this purpose is the generalization error, defined by

\[ E(f) := \inf_{\{\rho\}} \int_Y (f(x) - y)^2d\rho, \]

which is minimized by the regression function \( \hat{f} \), defined by

\[ f_{\rho}(x) := \int_Y yd\rho(y|x). \]

We do not know this ideal minimizer \( f_{\rho} \), since \( \rho \) is unknown, but we have access to random examples from \( X \times Y \) sampled according to \( \rho \). Let \( L^2_{\rho_X} \) be the Hilbert space of \( \rho_X \) square integrable function on \( X \), with norm denoted by \( \| \cdot \|_\rho \). Then for arbitrary \( f \in L^2_{\rho_X} \), there holds

\[ E(f) - E(f_{\rho}) \leq \| f - f_{\rho} \|_\rho^2, \]

with the assumption \( f_{\rho} \in L^2_{\rho_X} \).

**B. The generalization capability of ELM with Gaussian kernel**

Let \( \pi_M f(x) = \min\{|M, |f(x)||| \sgn(f(x)) \) be the truncation operator on \( f(x) \) at level \( M \). As \( y \in [-M, M] \), it is easy to check that

\[ \| \pi_M f_{\mu,s,n} - f_{\mu,s,n} \|_\rho \leq \| \mu_{s,n} - f_{\mu,s,n} \|_\rho. \]

Thus, the aim of this section is to bound

\[ E(\mu_{s,n} f_{\mu,s,n} - f_{\mu,s,n}) \leq E(\mu_{s,n} f_{\mu,s,n} - f_{\mu,s,n})^2. \]

The error clearly depends on \( z \) and therefore has a stochastic nature. As a result, it is impossible to say anything about \( E(\mu_{s,n} f_{\mu,s,n}) \) in general for a fixed \( z \). Instead, we can look at its behavior in statistics as measured by the expected error

\[ E_{\rho^n}(\| \pi_M f_{\mu,s,n} - f_{\mu,s,n} \|_\rho)^2 := \int_{\mathbb{R}^m} \| \pi_M f_{\mu,s,n} - f_{\mu,s,n} \|_\rho d\rho^n, \]
where the expectation is taken over all realizations $z$ obtained for a fixed $m$, and $\rho^m$ is the $m$ fold tensor product of $\rho$. In following Theorem 2 we give an upper bound estimate for $\sigma$ in the sense of expectation.

**Theorem 2:** Let $d, s, n, m \in \mathbb{N}$, $\varepsilon > 0$, $r \in \mathbb{R}$ and $f_{x, \sigma, s, n}$ be defined as in (4). If $f_\rho \in F^r$ with $r \leq s$, $\sigma = m^{\frac{2d}{r+s}}$, and $n = [m^{\frac{1}{r+d}}]$, then with probability at least $1 - 2\exp\{-c m^{\frac{d}{r+d}}\}$ (with respect to $\mu^n$), there holds

$$E_{\rho^m}(\|\pi_M f_{x, \sigma, s, n} - f_\rho\|^2_{\rho}) \leq C \left( m^{-\frac{d}{r+s}} \log m + m^{-\frac{d}{r+d}} \right),$$

(10)

where $[t]$ denotes the integer part of the real number $t$, and $C$ are constants depending only on $M, s, r$ and $d$.

It can be found in Theorem 2 that a new quantity $\varepsilon$ is introduced to quantify the randomness of $\rho$. It follows from (10) that $\varepsilon$ describes the uncertainty between the confidence and generalization capability. That is, we cannot obtain both extremely small generalization error and high confidence. This means that there also exists an uncertainty problem for ELM learning. Accordingly, Theorem 2 shows that it is reasonable to choose a very small $\varepsilon$, under which circumstance, we can deduce a learning rate close to $m^{-\frac{d}{r+d}} \log m$ with a tolerable confidence, provided $r \leq d$.

Before drawing the conclusion that ELM with Gaussian kernel degrades the generalization capability, we should verify the optimality of the learning rate deduced in (10). For this purpose, we give the following Proposition 2.

**Proposition 2:** Let $d = s = 1, n, m \in \mathbb{N}$, $\beta > 0$, $0 < \varepsilon < 1$, $r = 1 - \varepsilon$ and $f_{x, \sigma, s, \lambda, n}$ be defined as in (4). If $f_\rho \in F^r$, $\sigma = m^{\frac{2d}{r+s}}$, and $n = [m^{\frac{1}{r+d}}]$, then with probability at least $1 - 2\exp\{-c m^{\frac{d}{r+d}}\}$, there holds

$$C_1 m^{-\frac{d}{r+s}} \leq E(\|\pi_M f_{x, \sigma, s, \lambda, n} - f_\rho\|^2_{\rho}) \leq C_2 m^{-\frac{d}{r+d}} \log m,$$

(11)

where $C_1$ and $C_2$ are constants depending only on $r$ and $M$.

Modulo an arbitrary small number $\varepsilon$ and the logarithmic factor, the upper and lower bounds of (11) are asymptotically identical. Therefore, the established learning rate in Theorem 2 is almost essential. This means that the established learning rate (10) can not be essentially improved, at least for the univariate case.

Now, we turn to justify the optimality of the selections of $\sigma$ and $n$ in Theorem 2. The optimality of $\sigma$ can be directly derived from the uncertainty problem of ELM. To be detail, according to Theorem 1 and Proposition 1 the optimal selection of $\sigma$ is to set $\sigma = n^{\frac{2d}{d}}$. Noting that $n = [m^{\frac{1}{r+d}}]$, it is easy to deduce that the optimal selection of $\sigma$ is $m^{\frac{2d}{d+r}}$.

Finally, we show the optimality of the parameter $n$. The main principle to qualify it is the known “bias and variance” dilemma [2], which declares that a small $n$ may derive a large bias (approximation error), while a large $n$ deduces a large variance (sample error). The best $n$ is thus obtained when the best comprise between the conflicting requirements of small bias and small variance is achieved. In the proof of Theorem 2 we can find that the quantity $n = \left[ m^{\frac{d}{2(r+d)}} \right]$ is selected to balance the approximation and sample errors. Therefore, we can conclude that $n$ is optimal in the sense of “bias and variance” balance.

Based on the above assertions, we compare Theorem 2 with some related work and propose then the main viewpoint of this section. Imposing the same smooth assumption on the regression function, the optimal learning rate of the FNN with Gaussian kernel was established in (17), where Lin et al. deduced that FNNs can achieve the learning rate as $m^{-2r/(2r+d)} \log m$. They also showed that there are $\left[ m^{d/(2r+d)} \right]$ neurons needed to deduce the almost optimal learning rate. Similarly, Eberts and Steinwart [3] have also built an almost optimal learning rate analysis for the support vector machine (SVM) with the Gaussian kernel. They showed that, modulo an arbitrary small number, both the upper and lower bounds of learning rate of SVM with Gaussian can also attain the optimal learning rate, $m^{-2r/(2r+d)}$. However, Theorem 2 and Proposition 2 imply that the learning rate of ELM with Gaussian kernel can not be faster than $m^{-r/(r+d)}$. Noting $m^{-2r/(2r+d)} < m^{-r/(r+d)}$ and $m^{d/(2r+d)} < m^{d/(r+d)}$, we find that the prediction accuracy of ELM with Gaussian kernel is much larger than that of FNN even though more neurons are used in ELM. Furthermore, it should be pointed out that if the numbers of utilized neurons in ELM and FNN are identical, then the learning rate of ELM is even worse. Indeed, if $n = \left[ m^{d/(2r+d)} \right]$, then the learning rate of ELM with Gaussian kernel can not be faster than $m^{-r/(2r+d)}$.

Therefore, we can draw the conclusion that ELM with Gaussian kernel degrades the generalization capability.

**IV. REMEDY OF THE DEGRADATION**

As is shown in the previous section, ELM with inappropriately selected activation function suffers from the uncertainty problem and generalization degradation phenomenon. To circumvent the former one, we can employ a multiple training strategy which has already been proposed in [18]. The main focus of this section is to tackle the generalization capability degradation phenomenon. For this purpose, we use the $l^2$ coefficient regularization strategy [19] in the second stage of ELM. That is, we implement the following strategy to build up the ELM estimator:

$$f_{x, \sigma, s, \lambda, n} = \arg\min_{f \in \mathcal{H}_{s, n}} \left\{ \frac{1}{m} \sum_{i=1}^{m} (f(x_i) - y_i)^2 + \lambda \Omega(f) \right\},$$

(12)

where $\lambda = \lambda(m) > 0$ is a regularization parameter and

$$\Omega(f) = \sum_{i=1}^{m} |a_i|^2, \text{ for } f = \sum_{i=1}^{m} a_i K_{\sigma,s}(\theta_i, x) \in \mathcal{H}_{s, n}.$$

The following theorem shows that the generalization capability of ELM with Gaussian kernel can be essentially improved by using the regularization technique, provided the number of neurons is appropriately adjusted.

**Theorem 3:** Let $d, s, n, m \in \mathbb{N}$, $\varepsilon > 0$ and $f_{x, \sigma, s, \lambda, n}$ be defined in (12). If $f_\rho \in F^r$ with $d/2 \leq r \leq d$, $\sigma = m^{\frac{2d}{r+d} + \varepsilon}$, 1

1The proof of this conclusion is the same as that of Theorem 2 we omit it for the sake of brevity.
\[ n = \left\lceil m \frac{\log r}{\log \lambda} \right\rceil, \quad s \geq r \text{ and } \lambda = m^{-\frac{2r}{2r+2d}}, \] 
then with confidence at least \( 1 - 2 \exp\{-cm \frac{\log r}{\log \lambda} \} \) (with respect to \( \mu^n \)), there holds 
\[ C_1 m^{-\frac{2d}{2r+2d}} \leq E_{\mu^n}(\|Mf_{x,\sigma,s,\lambda, n} - f\|_p^2) \leq C_2 m^{-\frac{2d}{2r+2d} + \varepsilon} \log m, \] 
(13) 
where \( C_1 \) and \( C_2 \) are constants depending only on \( d, r, s \) and \( M \).

Theorem 5 shows that, up to an arbitrary small real number \( \varepsilon \) and the logarithmic factor, the regularized ELM estimator (12) can achieve a learning rate as fast as \( m^{-2r/(2r+d)} \) with high probability. Noting that \( m^{-2r/(2r+d)} < m^{-r/(r+d)} \) we can draw the conclusion that \( l^2 \) coefficient regularization technique can essentially improve the generalization capability of ELM with Gaussian kernel. Furthermore, as is shown above, the best learning rates of both SVM and FNN with Gaussian kernel asymptotically equal to \( m^{-2r/(2r+d)} \). Thus, Theorem 5 illustrates that the regularization technique not only improves the generalization capability of ELM with Gaussian kernel, but also optimizes its generalization capability. In other words, implementing \( l^2 \) coefficient regularization in the second stage, ELM with Gaussian kernel can be regarded as an almost optimal FNN learning strategy.

However, it should also be pointed out that the utilized neurons of regularized ELM is much larger than that of the FNN. Indeed, to obtain the same optimal learning rate, \( m^{-2r/(2r+d)} \), there are \( m^{2d/(2r+d)} \) neurons required in ELM with Gaussian kernel, while the number of utilized neurons in the traditional FNN learning is \( m^{d/(2r+d)} \). Therefore, although regularized ELM can attain the almost optimal learning rate with high probability, the price to obtain such a rate is higher than that of FNN.

V. PROOFS

A. Proof of Theorem 1

To prove Theorem 1 we need the following lemmas. The first one can be found in [10], which is an extension of Lemma 2.1 in [31].

**Lemma 1:** Let \( f \in C(I^d) \). There exists an \( F \in C(\mathbb{R}^d) \) satisfying
\[ F(x) = f(x), \quad x \in I^d \]
such that for arbitrary \( x \in I^d, \|h\| < \delta \leq 1 \), there holds
\[ \|F\|_\infty := \sup_{x \in I^d} |F(x)| \leq \|f\| = \sup_{x \in I^d} |f(x)| \]
and
\[ \omega_r \mu^d(F, \delta) \leq \omega_r \mu^d(f, \delta). \] (14)

To state the next lemma, we should introduce a convolution operator concerning the kernel \( K_{\sigma,s} \). Denote
\[ K_{\sigma,s} * F(x) := \int_{\mathbb{R}^d} F(y) K_{\sigma,s}(x-y) dy. \]
The following Lemma 2 gives an error estimate for the deviation of continuous function and its Gaussian convolution, which can be deduced from [5] Theorem 2.2.

**Lemma 2:** Let \( F \in C(\mathbb{R}^d) \) be a bounded and uniformly continuous function defined on \( \mathbb{R}^d \). Then,
\[ \|F - K_{\sigma,s} * F\|_\infty \leq C_s \omega_{s, R}(F, \sigma). \] (15)

Let \( J \) be arbitrary compact subset of \( \mathbb{R}^d \). For \( l \geq 0 \), denote by \( T_l \) the set of trigonometric polynomials defined on \( J \) with degree at most \( l \). The following Nikol’skii inequality can be found in [1].

**Lemma 3:** Let \( 1 \leq p < q \leq \infty \), \( l \geq 1 \) be an integer, and \( T_l \in T_l^d \). Then,
\[ \|T_l\|_{L^q(J)} \leq C_l^{\frac{1}{2} - \frac{1}{q}} \|T_l\|_{L^p(J)}, \]
where the constant \( C \) depends only on \( d \).

For further use, we should also introduce the following probabilistic Bernstein inequality for random variables, which can be found in [2].

**Lemma 4:** Let \( \xi \) be a random variable on a probability space \( Z \) with mean \( E(\xi) \), variance \( \gamma^2(\xi) = \gamma^2_\xi \). If \( |\xi(z) - E(\xi)| \leq M_{\xi} \) for almost all \( z \in Z \). then, for all \( \varepsilon > 0 \),
\[ \mathbb{P}\left\{ \left\| \frac{1}{n} \sum_{i=1}^n \xi(z_i) - E(\xi) \right\| \geq \varepsilon \right\} \leq 2 \exp\left\{ - \frac{ne^2}{2} \left( \frac{\gamma^2_\xi + \frac{1}{3} M_{\xi} \varepsilon}{\varepsilon} \right) \right\}. \]

By the help of Lemma 3 and Lemma 4 we are in a position to give the following probabilistic Marcinkiewicz-Zygmund inequality for trigonometric polynomials.

**Lemma 5:** Let \( J \) be a compact subset of \( \mathbb{R}^d \) and \( 0 < p \leq \infty \). If \( \Xi = \{ \theta_i \}_{i=1}^\infty \) is a set of i.i.d. random variables drawn on \( J \) according to arbitrary distribution \( \mu \), then
\[ \frac{1}{2} \|T_l\|_p^p \leq \frac{1}{n} \sum_{i=1}^n |T_l(\theta_i)|^p \leq \frac{3}{2} \|T_l\|_p^p, \quad \forall T_l \in T_l^d \] (16)
holds with probability at least
\[ 1 - 2 \exp\left\{ - \frac{C_p n}{l^2} \right\}, \]
where \( C_p \) is a constant depending only on \( d \) and \( p \).

**Proof:** Since we model the sampling set \( \Xi \) is a sequence of i.i.d. random variables in \( J \), the sampling points are a sequence of functions \( \theta_i = \theta_1(\omega) \) on some probability space \( (\Omega, \mathcal{F}, \mathbb{P}) \). Without loss of generality, we assume \( \|T_l\|_p = 1 \) for arbitrary fixed \( p \). If we set \( \xi^p_i(T_l) = |T_l(\theta_i)|^p \), then we have
\[ \frac{1}{n} \sum_{i=1}^n |T_l(\theta_i)|^p - E\xi_i^p = \frac{1}{n} \sum_{i=1}^n |T_l(\theta_i)|^p - \|T_l\|_p^p, \]
where we use the equality
\[ E\xi_i^p = \int_{\Omega} |T_l(\eta(\omega))|^p d\omega_j = \int_{\Omega} |T_l(\theta)|^p d\theta = \|T_l\|_p^p = 1. \]
Furthermore,
\[ |\xi^p_j - E\xi^p_j| \leq \sup_{\omega \in \Omega} |T_l(\theta(\omega))^p - ||T_l||_p^p| \leq ||T_l||_\infty^p - ||T_l||_p^p. \]
It follows from Lemma 3 that
\[ ||T_l||_\infty \leq C_l^p ||T_l||_p = C_l^p. \]
Hence
\[ |\xi^p_j - E\xi^p_j| \leq (C_l^d - 1). \]
On the other hand, we have
\[
\gamma^2 \xi = E((\xi p)^2) - (E(\xi p))^2 = \int_{\Omega} |T_l(\theta(\omega))|^2 p d\omega - \left(\int_{\Omega} |T_l(\theta(\omega))|^p d\omega\right)^2 = \|T_l\|^2_p - \|T_l\|^2_p.
\]
Then using Lemma 3, again, there holds
\[
\gamma^2 \xi \leq C l^{2dp(\frac{1}{p} - \frac{1}{2p})}\|T_l\|^2_p - \|T_l\|^2_p = (C l^{d} - 1).
\]
Thus it follows from Lemma 2 that with confidence at least
\[
1 - 2\exp\left\{-\frac{ne^2}{2(\gamma^2 + \frac{5}{4} M n)}\right\} \geq 1 - 2\exp\left\{-\frac{ne^2}{2(\gamma^2 + \frac{5}{4} (C l^{d} - 1) n)}\right\},
\]
there holds
\[
\frac{1}{n} \sum_{i=1}^{n} |T_l(\theta_i)|^p - \|T_l\|^p_p \leq \varepsilon.
\]
This means that if \( X \) is a sequence of i.i.d. random variables, then the Marcinkiewicz-Zygmund inequality
\[
(1 - \varepsilon)\|T_l\|^p_p \leq \frac{1}{n} \sum_{i=1}^{n} |T_l(\theta_i)|^p \leq (1 + \varepsilon)\|T_l\|^p_p
\]
holds with probability at least
\[
1 - 2\exp\left\{-\frac{C n}{l}\right\}.
\]
Then (16) is verified by setting \( \varepsilon = \frac{1}{2}. \)

To state the next lemma, we need introduce the following definitions. Let \( X \) be a finite dimensional vector space with norm \( \|\cdot\|_X \), and \( Z \subset X^* \) be a finite set. We say that \( Z \) is a norm generating set for \( X \) if the mapping \( T_z : X \rightarrow R^{\text{Card}(Z)} \) defined by \( T_z(x) = (z(x))_{z \in Z} \) is injective, where \( \text{Card}(Z) \) is the cardinality of the set \( Z \) and \( T_z \) is named as the sampling operator. Let \( W := T_z(X) \) be the range of \( T_z \), then the injectivity of \( T_z \) implies that \( T_{z^{-1}} : W \rightarrow X \) exists. Let \( R^{\text{Card}(Z)} \) have a norm \( \|\cdot\|_{R^{\text{Card}(Z)}} \), with \( \|\cdot\|_{R^{\text{Card}(Z)}} \) being its dual norm on \( R^{\text{Card}(Z)} \). Equipping \( W \) with the induced norm, and let \( \|T_{z^{-1}}\| := \|T_{z^{-1}}\|_{W \rightarrow X} \). In addition, let \( K_+ \) be the positive cone of \( R^{\text{Card}(Z)} \): that is, all \( (r_z) \in R^{\text{Card}(Z)} \) for which \( r_z \geq 0 \). Then the following Lemma 4 can be found in [20].

Lemma 6: Let \( Z \) be a norm generating set for \( X \), with \( T_z \) being the corresponding sampling operator. If \( y \in X^* \) with \( \|y\|_{X^*} \leq A \), then there exist real numbers \( \{a_z\}_{z \in Z} \) depending only on \( y \) such that for every \( x \in X \),
\[
y(x) = \sum_{z \in Z} a_z z(x),
\]
and
\[
\|\{a_z\}\|_{R^{\text{Card}(Z)}} \leq A \|T_{z^{-1}}\|.
\]
Also, if \( W \) contains an interior point \( v_0 \in K_+ \) and if \( y(T_{z^{-1}}v) \geq 0 \) when \( v \in V \cap K_+ \), then we may choose \( a_z \geq 0 \).

Using Lemma 4 and Lemma 3 we can deduce the following probabilistic numerical integral formula for trigonometric polynomials.

Lemma 7: Let \( J \) be a compact subset of \( R^d \). If \( \Xi = \{\theta_i\}_{i=1}^{n} \) are i.i.d. random variables drawn according to arbitrary distribution \( \mu \), then there exists a set of real numbers \( \{c_i\}_{i=1}^{n} \) such that
\[
\int_{J} T_i(x) dx = \sum_{i=1}^{n} c_i T_i(\theta_i), \forall T_i \in \mathcal{P}^{d}_l
\]
holds with probability at least
\[
1 - 2\exp\left\{-\frac{C n}{l^d}\right\},
\]
subject to
\[
\sum_{i=1}^{n} |c_i|^2 \leq C/n,
\]
where \( C_1 \) and \( C_2 \) are constants depending only on \( d \).

Proof: In Lemma 4, we take \( X = T_{z^{-1}} \), \( \|T_{l}\|_{X} = \|T_{l}\|_{p} \), and \( Z \) to be the set of point evaluation functions \( \{\delta_{\theta_i}\}_{i=1}^{n} \). The operator \( T_z \) is then the restriction map \( T_l \mapsto T_l \), with
\[
\|f\|_{L_{p}^{Z}} := \left\{\left(\frac{1}{n} \sum_{i=1}^{n} \left|f(\theta_i)\right|^p\right)^{\frac{1}{p}}\right\}, \quad 0 < p < \infty,
\]
\[
\sup_{1 \leq i \leq n} \left|\left|\left. f(\theta_i) \right| \right|_{L_{p}}\right|, \quad p = \infty.
\]
It follows from Lemma 5 with \( p = 2 \) that with confidence at least
\[
1 - 2\exp\left\{-\frac{C n}{l^d}\right\},
\]
there holds \( \|T_{z^{-1}}\| \leq 2. \) We now take \( y \) to be the functional
\[
y : T_l \mapsto \int_{J} T_l(x) dx.
\]
By H"older inequality, \( \|y\|_{X^*} \leq |J| \), where \( |J| \) denotes the volume of \( J \). Therefore, Lemma 4 shows that
\[
\int_{J} T_l(x) dx = \sum_{i=1}^{n} c_i T_i(\theta_i)
\]
holds with confidence at least
\[
1 - 2\exp\left\{-\frac{C n}{l^d}\right\},
\]
subject to
\[
\frac{1}{n} \sum_{i=1}^{n} \left|\left|\left. c_i \right| \right|_{L_{p}^{Z}}\right|^{2} - 2|J|.
\]
Therefore, we obtain that \( \sum_{i=1}^{n} |c_i|^2 \leq C/n \), where \( C \) is a constant depending only on \( d \).

Let \( B = [-a, 1 + a]^d \) and \( \mathcal{P}^{d}_l \) be the class of algebraic polynomials defined on \( B \) with degree at most \( l \). By the help of the above lemma, we can get the following probabilistic numerical integral formula for algebraic polynomials.

Lemma 8: If \( \Xi = \{\eta_i\}_{i=1}^{n} \) are i.i.d. random variables drawn according to arbitrary distribution \( \mu \), then there exists a set of real numbers \( \{a_i\}_{i=1}^{n} \) such that
\[
\int_{B} P_l(x) dx = \sum_{i=1}^{n} a_i P_l(\eta_i), \forall P_l \in \mathcal{P}^{d}_l
\]
holds with confidence at least
\[ 1 - 2\exp\left\{ -\frac{C_1 n}{t^2} \right\}, \]
subject to
\[ \sum_{i=1}^{m} |a_i|^2 \leq \frac{C}{n}, \]
where \( C_1 \) and \( C \) are constant strictly depending only on \( d \).

**Proof:** Since \( x = (x_{(1)}, \ldots, x_{(d)}) \), we have
\[
\int_{B} f(x)dx = \int_{-a}^{1+a} \cdots \int_{-a}^{1+a} f(x_{(1)}, \ldots, x_{(d)})dx_{(1)} \cdots dx_{(d)}.
\]
Set \( x_{(i)} = (1 + |a|) \cos v_i, i = 1, \ldots, d \), then we have
\[
\int_{B} P_t(x)dx = \int_{-a}^{1+a} \cdots \int_{-a}^{1+a} P_t((1 + |a|) \cos v_1, \ldots, (1 + |a|) \cos v_d) \times d(1 + |a|) \cos v_1 \cdots d(1 + |a|) \cos v_d = \int_{J_a} T_{t+d}(v)dv,
\]
where \( J_a \) is a compact subset of \( \mathbf{R}^d \) and
\[
T_{t+d}(v) = (- (1 + |a|))^{d} P_t((1 + |a|) \cos v_1, \ldots, (1 + |a|) \cos v_d) \times \cos v_1 \cdots \cos v_d.
\]
Hence, \( T_{t+d} \in \mathcal{P}^d_{t,d} \) and then Lemma 8 can be directly deduced from Lemma 7.

By using Lemma 8 we can deduce the following error estimator.

**Lemma 9:** Let \( a > 0, u, l \in \mathbf{N} \). If \( \Xi := \{\eta_i\}_{i=1}^{n} \) is a random variable drawing independently according to \( \mu \) on \([-a, 1 + a]\), then with confidence at least \( 1 - 2\exp\{-cn/(u + l)^d\} \), there holds
\[
\inf_{g_n \in \mathcal{K}_{n,s,n}} \|K_{\sigma,s} \ast F - g_n\| \leq C_s \left( \omega_{s+1}f(1/l) + a \|f\|_{\sigma}d + \sigma^{-d} \frac{2^u}{u!\sigma^2} \right),
\]
where \( C_s \) is a constant strictly depending only on \( d \) and \( s \).

**Proof:** For arbitrary \( f \in \mathcal{C}(I^d) \), let \( F \) and \( K_{\sigma,s} \ast F \) defined as in Lemma 1 and Lemma 2 respectively. Then,
\[
K_{\sigma,s} \ast F = \int_{\mathbf{R}^d} K_{\sigma,s}(x - y)F(y)dy = \int_{B} K_{\sigma,s}(x - y)F(y)dy + \int_{\mathbf{R}^d - B} K_{\sigma,s}(x - y)F(y)dy.
\]
At first, we give an upper bound estimate for \( \int_{\mathbf{R}^d - B} K_{\sigma,s}(x - y)F(y)dy \). It follows from Lemma 1 and the definition of \( K_{\sigma,s} \) that
\[
\left| \int_{\mathbf{R}^d - B} K_{\sigma,s}(x - y)F(y)dy \right| \leq \|f\|_{L^s} \sum_{j=1}^{s} \left( \int_{-\infty}^{\infty} \left\{ -\frac{2||x-y||^2}{j^2\sigma^2} \right\} dy \right)^{d/2} \times \left( \int_{\mathbf{R}^d - B} \exp \left\{ -\frac{2||x-y||^2}{j^2\sigma^2} \right\} dt \right)^{d/2} \leq 2\|f\|_{L^s} \sum_{j=1}^{s} \left( \int_{-\infty}^{\infty} \left\{ -\frac{2||x-y||^2}{j^2\sigma^2} \right\} dt \right)^{d/2} \times \left( \int_{\mathbf{R}^d} \exp \left\{ -\frac{2\sigma t}{j^2\sigma^2} \right\} dt \right)^{d/2} \leq C_s \|f\|_{L^s} \alpha^{-d},
\]
where \( C_s \) is a constant strictly depending only on \( d \) and \( r \).

On the other hand, for \( F \in \hat{C}(B) \) and \( s \in \mathbf{N} \), it is well known [4] that there exists a \( P_t \in \mathcal{P}^d_t \) and absolute constants \( C_1, C_2 \) such that
\[
\|F - P_t\| \leq C_1 \inf_{P_t \in \mathcal{P}^d_t} \|F - P_t\| = C_1 E_t(F), \tag{17}
\]
and
\[
\|P_t\|_{L^s} \leq C_2 \|F\|_{L^s} \leq C_2 \|f\|_{L^s}, \tag{18}
\]
Then, for arbitrary \( \{b_i\}_{i=1}^{n} \subset \mathbf{R} \), there holds
\[
\int_{B} F(y)K_{\sigma,s}(x - y)dy - \sum_{i=1}^{n} b_i K_{\sigma,s}(x - \eta_i) = \int_{B} (F(y) - P_t(y))K_{\sigma,s}(x - y)dy + \int_{B} P_t(y)K_{\sigma,s}(x - y)dy - \sum_{i=1}^{n} b_i K_{\sigma,s}(x - \eta_i). \tag{19}
\]
Let \( u \in \mathbf{N} \). Then, for arbitrary univariate algebraic polynomial \( q \) of degree not larger than \( u \), we obtain
\[
\int_{B} P_t(y)K_{\sigma,s}(x - y)dy - \sum_{i=1}^{n} b_i K_{\sigma,s}(x - \eta_i) = \int_{B} P_t(y)(K_{\sigma,s}(x - y) - q(x - y))dy + \int_{B} P_t(y)q(x - y)dy - \sum_{i=1}^{n} b_i (K_{\sigma,s}(x - \eta_i) - q(x - \eta_i)) - \sum_{i=1}^{n} b_i q(x - \eta_i).
\]
Since \( P_t(y)q(x - y) \in \mathcal{P}^d_{t+d}(B) \) for fixed \( x \), it follows from Lemma 8 that with confidence at least \( 1 - 2\exp\{-cn/(u + l)^d\} \), there exists a set of real numbers \( \{w_i\}_{i=1}^{n} \subset \mathbf{R} \) such that
\[
\int_{B} P_t(y)q(x - y)dy = \sum_{i=1}^{n} w_i P_t(\eta_i)q(x - \eta_i).
\]
If we set \( a_i = w_i P_l(\eta_i) \), then
\[
\int_B P_l(y) K_{\sigma,s}(x-y)dy - \sum_{i=1}^n a_i K_{\sigma,s}(x-\eta_i)
\]
\[
= \int_B P_l(y) (K_{\sigma,s}(x-y) - q(x-y))dy
\]
\[
- \sum_{i=1}^n w_i P_l(\eta_i) (K_{\sigma,s}(x-\eta_i) - q(x-\eta_i))
\]
holds with confidence at least \( 1 - 2 \exp\{-cn/(u+l)^d\} \). Under this circumstance,
\[
\left\| \int_B P_l(y) K_{\sigma,s}(\cdot-y)dy - \sum_{i=1}^n a_i K_{\sigma,s}(\cdot-\eta_i) \right\|_{L^d}
\]
\[
\leq \left\| \int_B P_l(y) (K_{\sigma,s}(\cdot-y) - q(\cdot-y))dy \right\|_{L^d}
\]
\[
+ \left\| \sum_{i=1}^n w_i P_l(\eta_i) (K_{\sigma,s}(\cdot-\eta_i) - q(\cdot-\eta_i)) \right\|_{L^d}
\]
To bound the above quantities, define
\[
L_j(v) := \exp - \frac{2v}{j^2\sigma^2},
\]
Let \( T^s_u([0,(1+a)^2]) \) be the set of univariate algebraic polynomials of degrees not larger than \( u \) defined on \([0,(1+a)^2]\), and set \( q_d^s = \arg\min_{q \in T^s_u([0,(1+a)^2])} \| L_j - q \|_1 \), and
\[
q_u(v) := \sum_{j=1}^s \left( \frac{s}{j} \right) \frac{1}{j^d} \left( \frac{2}{\sigma^2\pi} \right)^{d/2} q_d^s(v).
\]
Then, it follows from (18) that
\[
\left\| \int_B P_l(y) K_{\sigma,s}(\cdot-y) - q_u(\cdot-y) \right\|_{L^d}
\]
\[
\leq C \| f \|_{L^d} \| K_{\sigma,s}(\cdot-y) - q_u(\cdot-y) \|_{L^d}
\]
\[
\leq C \| f \|_{L^d} \sum_{j=1}^r \left( \frac{r}{j} \right) \frac{1}{j^d} \left( \frac{2}{\sigma^2\pi} \right)^{d/2}
\]
\[
\times \inf_{q \in T^s_u([0,(1+a)^2])} \| L_j - q \|.
\]
On the other hand, since \( \sum_{i=1}^n \| w_i \| \leq \sqrt{n} \sum_{i=1}^n \| w_i \|^2 \leq C \), we also obtain
\[
\left\| \sum_{i=1}^n w_i P_l(\eta_i) (K_{\sigma,s}(\cdot-\eta_i) - q_u(\cdot-\eta_i)) \right\|
\]
\[
\leq C \| f \|_{L^d} \sum_{j=1}^s \left( \frac{s}{j} \right) \frac{1}{j^d} \left( \frac{2}{\sigma^2\pi} \right)^{d/2}
\]
\[
\times \inf_{q \in T^s_u([0,(1+a)^2])} \| L_j - q \|.
\]
Thus, the only thing remainder is to bound \( \int_B (F(y) - P_l(y)) K_{\sigma,s}(x-y)dy \). It follows from (12) that
\[
\int_B (F(y) - P_l(y)) K_{\sigma,s}(x-y)dy
\]
\[
\leq E_l(F) \times \int_B K_{\sigma,s}(x-y)dy \leq C_s \omega_s, R_s (F, 1/l),
\]
where we use the fact
\[
\int_B K_{\sigma,s}(x-y)dy \leq 1
\]
and the known Jackson inequality (11) in the last inequality. All above together with Lemma (1) yields that
\[
\inf_{g_n \in H_{\sigma,s,n}} \| K_{\sigma,s} * F - g_n \| \leq C_s \omega_s, l^d (f, 1/l)
\]
\[
+ C_s a \| f \| \sigma^d + C \| f \| \sum_{j=1}^s \left( \frac{s}{j} \right) \frac{1}{j^d} \left( \frac{2}{\sigma^2\pi} \right)^{d/2}
\]
\[
\times \inf_{q \in T^s_u([0,(1+a)^2])} \| L_j - q \|.
\]
holds with confidence at least \( 1 - 2 \exp\{-cn/(u+l)^d\} \). Furthermore, it is straightforward to check, using the power series (19, P.136) for \( \exp\{-2v/(j\sigma^2)\} \) that
\[
\inf_{q \in T^s_u([0,(1+a)^2])} \| L_j - q \|
\]
\[
\leq C_s \sigma^{-d} \frac{2^u}{u! \sigma^2}.
\]
Thus, the proof of Lemma 9 is completed. 

By the help of the above nine lemmas, we can proceed the proof of Theorem 1 as follows.

**Proof of Theorem 1**

Since
\[
\inf_{g_n \in H_{\sigma,s,n}} \| f - g_n \|_{L^d} \leq \| f - K_{\sigma,s} * F \|_{L^d} + \| K_{\sigma,s} * F - g_n \|_{L^d},
\]
Setting \( \sigma = l^{-1/2} \), it follows from Lemma 2 and Lemma 9 that
\[
\inf_{g_n \in H_{\sigma,s,n}} \| f - g_n \|_{L^d} \leq C_s \left( \omega_{s,l^d}(f, l^{-1/2}) + a \| f \| \sigma^d + \sigma^{-d} \frac{(2\sigma^2)^u}{2^n u!} \right)
\]
holds with confidence at least \( 1 - 2 \exp\{-cn/(u+l)^d\} \). By the Stirling’s formula, it is easy to check that
\[
\sigma^{-d} \frac{(2\sigma^2)^u}{2^n u!} \leq C \frac{u! (u/2)^u}{2^n u!} \leq C \frac{u^d}{(2d)^u} \leq C l^{-d/2}
\]
with \( u = 2d \). Therefore, we obtain
\[
\inf_{g_n \in H_{\sigma,s,n}} \| f - g_n \| \leq C_s \left( \omega_{s,l^d}(f, l^{-1/2}) + a \| f \| \sigma^{-d/2} \right),
\]
with confidence at least \( 1 - 2 \exp\{-cn/l^d\} \). Therefore, Theorem 1 follows by noticing \( \sigma = 1/\sqrt{l} \).

**B. Proof of Proposition 1**

To prove Proposition 1 we need the following two lemmas, the first one concerning Bernstein inequality for \( H_{\sigma,s,n} \) can be easily deduced from (6, eqs (3.1)).

**Lemma 10:** Let \( d = 1 \), \( s = 1 \), and \( \sigma \geq n^{-1/2} \). Then, for arbitrary \( g_n \in H_{\sigma,s,n} \), there holds
\[
\| g_n \|_{[0,1]} \leq C n^{1/2} \| g_n \|_{[0,1]},
\]
where \( C \) is an absolute constant.
By the help of the Bernstein inequality, the standard method in approximation theory [4 Chap. 7] yields the following Lemma 11.

Lemma 11: Let \( d = 1, s = 1, r \in \mathbb{N}, \sigma \geq n^{-1/2} \) and \( f \in C(I^1) \). If
\[
\sum_{n=1}^{\infty} n^{r/2-1} \text{dist}(f, \mathcal{H}_{\sigma,1,n}) < \infty,
\]
then \( f \in \mathcal{F}' \), where \( \text{dist}(f, \mathcal{H}_{\sigma,1,n}) = \inf_{g \in \mathcal{H}_{\sigma,1,n}} \| f - g \|_{I^1} \).

Proof: Let \( g_n := \arg \inf_{g \in \mathcal{H}_{\sigma,1,n}} \| f - g \|_{I^1} \). For arbitrary \( n \in \mathbb{N} \), set \( n_0 \) such that
\[
2^{n_0} \leq n \leq 2^{n_0+1}.
\]
It is easy to see that
\[
\sum_{n=1}^{\infty} n^{r/2-1} \text{dist}(f, \mathcal{H}_{\sigma,1,n}) < \infty,
\]
implies \( \text{dist}(f, \mathcal{H}_{\sigma,1,n}) \to 0 \) in \( C(I^1) \). Indeed, if it does not hold, then there exists an absolute constant \( C \) such that
\[
\text{dist}(f, \mathcal{H}_{\sigma,1,n}) \geq C > 0.
\]
Therefore,
\[
C \sum_{n=1}^{\infty} n^{-1} \leq \sum_{n=1}^{\infty} n^{\sigma-1} \text{dist}(f, \mathcal{H}_{\sigma,1,n}) < \infty,
\]
which is impossible. So we have
\[
f - g_2^{n_0} = \sum_{j=n_0}^{\infty} g_{2j+1} - g_{2j}.
\]
By Lemma 10 we then have
\[
\| g_{2j+1} - g_{2j} \|_{I^1} \leq C(2^{(j+1)/2}r)d \text{dist}(f, \mathcal{H}_{\sigma,1,2j}).
\]
Then direct computation yields that
\[
\| g_{2j+1} - g_{2j} \|_{I^1} \leq C \sum_{j=1}^{\infty} \sum_{k=2j-1+1}^{2j} k^{r/2-1} \text{dist}(f, \mathcal{H}_{\sigma,1,k}) \leq C \sum_{k=1}^{\infty} k^{r/2-1} \text{dist}(f, \mathcal{H}_{\sigma,1,k}) < \infty.
\]
So \( \{g_{2j}\} \) is the Cauchy sequence of \( \mathcal{F}' \). Differentiating (20), we have
\[
f' - g_2^{n_0} = \sum_{j=n_0}^{\infty} g_{2j+1} - g_{2j}.
\]
Since \( \{g_{2j}\} \) is the Cauchy sequence of \( \mathcal{F}' \), we have \( f' - g_2^{n_0} \to 0 \) when \( n_0 \to \infty \), which implies \( f \in \mathcal{F}' \).

Now we continue the proof of Proposition 1.

Proof of Proposition 1: Let \( \epsilon \in (0, 1) \), and \( r = 1 - \epsilon \). It is obvious that there exists a function \( h_r \) satisfying \( h_r \in \mathcal{F}' \) and \( h_r \notin \mathcal{F}' \) with \( r' > r \). Assume
\[
\inf_{g \in \mathcal{H}_{\sigma,1,n}} \| f - g \| \leq C n^{-r/2-\epsilon}
\]
holds for all \( f \in \mathcal{F}' \), where \( C \) is a constant independent of \( n \). Then,
\[
\inf_{g \in \mathcal{H}_{\sigma,1,n}} \| h_r - g \| \leq C n^{-r/2-\epsilon}.
\]
Then,
\[
\sum_{n=1}^{\infty} n^{1/2-1} \text{dist}(h_r, \mathcal{H}_{\sigma,1,n}) = \sum_{n=1}^{\infty} n^{-1-\epsilon/2} < \infty.
\]
Therefore, it follows from Lemma 11 that \( h_r \in \mathcal{F}' \), which is impossible. Hence,
\[
\sup_{f \in \mathcal{F}'} \inf_{g \in \mathcal{H}_{\sigma,1,n}} \| f - g \| \geq C n^{-r/2-\epsilon}.
\]
This together with Theorem 1 finishes the proof of Proposition 1.

C. Proof of Theorem 2

The main tool to prove Theorem 2 is the following Lemma 12, which can be found in [8, Chap. 11].

Lemma 12: Let \( f_{\omega, \sigma, s, n} \) be defined as in (4). Then
\[
E_{\rho^m} \| \pi_M f_{\omega, \sigma, s, n} - f_{\rho} \|_{\rho}^2 \leq CM^2 \left( \log m + 1 \right) n \frac{n}{m} + 8 \inf_{f \in H_{\omega, \sigma, s, n}} \int_X |f(x) - f_{\rho}(x)|^2 d\rho X
\]
for some universal constant \( C \).

Now, we use Proposition 1 and Lemma 12 to prove Theorem 2.

Proof of Theorem 2: Since \( H_{\omega, \sigma, s, n} \) is a \( n \)-dimensional linear space, then Lemma 12 yields that
\[
E_{\rho^m} \| \pi_M f_{\omega, \sigma, s, n} - f_{\rho} \|_{\rho}^2 \leq CM^2 \left( \log m + 1 \right) n \frac{n}{m} + 8 \inf_{f \in H_{\omega, \sigma, s, n}} \int_X |f(x) - f_{\rho}(x)|^2 d\rho X.
\]
Therefore, it suffices to bound
\[
\inf_{g \in H_{\omega, \sigma, s, n}} \| g - f \|_X \leq C \left( \omega_0, l_d, f_{\rho}, \sigma \right) + \| f_{\rho} \|_{\sigma^d}
\]
holds with probability at least \( 1 - 2 \exp \{-c n \sigma^d \} \). Noting \( r \leq s \) and \( f_{\rho} \in \mathcal{F}' \), with probability at least \( 1 - 2 \exp \{-c n \sigma^d \} \), there holds
\[
\inf_{f \in H_{\omega, \sigma, s, n}} \| f - f_{\rho} \|_X^2 \leq C \left( \sigma^{2r} + \sigma^{2d} \right).
\]
Setting \( \sigma = n^{-1+\epsilon}/(2d) \), we observe that with probability at least \( 1 - 2 \exp \{-n^{\epsilon'} \} \), there holds
\[
\inf_{f \in H_{\omega, \sigma, s, n}} \| f - f_{\rho} \|_X^2 \leq C \left( n^{-r/d + \epsilon'/(2d)} + n^{-1+\epsilon} \right).
\]
Finally, choosing \( n = \left[ m^{1/(d+2)} \right] \), we obtain that with probability at least \( 1 - 2 \exp \{-n^{\epsilon'} \}, \) there holds
\[
E_{\rho^m} \| \pi_M f_{\omega, \sigma, s, n} - f_{\rho} \|_{\rho}^2 \leq C \left( m^{(1-r)/(d+2)} \log m + m \frac{d(1-r)}{d+2} \right).
\]
This finishes the proof of Theorem 2.
D. Proof of Proposition 2

To prove Proposition 2 we need the following three lemmas. The first one is the interpolation theorem of linear functionals, which can be found in [11, P.385].

Lemma 13: Let $C(Q)$ be the set of real valued continuous functions on the compact Hausdorff space Q. Let $S$ be an n-dimensional linear subspace of $C(Q)$ over $\mathbb{R}$. Let $L \neq 0$ be a real-valued linear functional on $S$. Then there exist points $x_1, x_2, \ldots, x_r$ in Q and nonzero real numbers $a_1, a_2, \ldots, a_r$, where $1 \leq r \leq n$, such that

$$L(s) = \sum_{i=1}^{r} a_i s(x_i), \ s \in S$$

and

$$\|L\| = \sup \{ |L(s)|: s \in S, \|s\|_Q \leq 1\} = \sum_{i=1}^{r} |a_i|.$$

By using Lemmas 13 and 10 we can obtain the following Bernstein inequality for ELM with Gaussian kernel in the metric of $L^2_{\rho x}$.

Lemma 14: Let $d = 1$, $s = 1$, and $\sigma \geq n^{-1/2}$. Then, for arbitrary $g_n \in \mathcal{H}_{\sigma, s, n}$, there holds

$$\|g_n\|_{\rho} \leq C n^{1/2} \|g_n\|_{\rho},$$

where $C$ is an absolute constant.

Proof: We apply Lemma 13 with $Q = [1/2, 1]$, $S = \mathcal{H}_{\sigma, s, n}$, and $L(s) = s'(1)$. It follows from Lemma 10 that

$$\|L\| = |s'(1)| \leq C n^{1/2} \|s(1)| = C_n^{1/2}. \ (22)$$

We deduce that there are $v_1, v_2, \ldots, v_r$ in $[1/2, 1]$ and $a_1, a_2, \ldots, a_r \in R$ so that for every $s \in \mathcal{H}_{\sigma, s, n}$,

$$|s'(1)| \leq \sum_{i=1}^{r} \frac{a_i}{C_n^{1/2}} \leq \sum_{i=1}^{r} \left| \frac{a_i}{C_n^{1/2}} \right| |s(v_i)|$$

with $1 \leq r \leq n$. By (22) we have

$$\sum_{i=1}^{r} \left| \frac{a_i}{C_n^{1/2}} \right| \leq 1.$$

So there is a sequence of numbers $\{c_i\}$ with $\sum_{i=1}^{r} |c_i| = 1$ such that

$$|s'(1)| \leq \sum_{i=1}^{r} |c_i| |s(v_i)|.$$

Now let $\phi : [0, \infty) \rightarrow [0, \infty)$ be a nondecreasing convex function. Using monotonicity and convexity, we have

$$\phi \left( \frac{|s'(1)|}{C_n^{1/2}} \right) \leq \phi \left( \sum_{i=1}^{r} |c_i| s(v_i) \right) \leq \sum_{i=1}^{r} |c_i| \phi \left( |s(v_i)| \right).$$

Applying this inequality with $s(t) = g_n(t + u - 1) \in \mathcal{H}_{\sigma, s, n}$, we get

$$\phi \left( \frac{|g_n'(u)|}{C_n^{1/2}} \right) \leq \sum_{i=1}^{r} |c_i| \phi \left( |P(v_i + u - b)| \right)$$

for every $P \in \mathcal{H}_{\sigma, s, n}$ and $u \in [1/2, 1]$. Since $x_i \in [1/2, 1]$ and $u \in [1/2, 1]$, then $v_i + u - 1 \in [0, 1]$ for each $i = 1, 2, \ldots, r$. Integrating on the interval $[1/2, 1]$ with respect to $u$, we obtain

$$\int_{1/2}^{1/2} \phi \left( \frac{|g_n'(u)|}{C_n^{1/2}} \right) du \leq \sum_{i=1}^{r} |c_i| \phi \left( |g_n(v_i)| \right).$$

We deduce that there are $\rho$ for every $P \in \mathcal{H}_{\sigma, s, n}$ and $u \in [1/2, 1]$. Since $x_i \in [1/2, 1]$ and $u \in [1/2, 1]$, then $v_i + u - 1 \in [0, 1]$ for each $i = 1, 2, \ldots, r$. Integrating on the interval $[1/2, 1]$ with respect to $u$, we obtain

$$\int_{1/2}^{1/2} \phi \left( \frac{|g_n'(u)|}{C_n^{1/2}} \right) du \leq \sum_{i=1}^{r} |c_i| \phi \left( |g_n(v_i)| \right) = \sum_{i=1}^{r} |c_i| \phi \left( |g_n(v_i)| \right).$$

Combining the last two inequalities and choosing $\phi(x) = x^2$, we finish the proof of Lemma 14.

Proof of Proposition 2. With the help of the above lemmas, we can use the almost same method as that in the proof of Proposition 1 to obtain

$$\sup_{f \in \mathcal{F}, g \in \mathcal{H}_{\sigma, s, n}} \|f - g\|_\rho \geq C n^{-r/2 - \varepsilon}.$$
Set $N_{2}(G, \varepsilon) = N(G|_{x}, \varepsilon, \delta_{2})$. The $l^{2}$-empirical covering number of $G$ is defined by

$$N_{2}(G, \varepsilon) := \sup_{m \in \mathbb{N}} \sup_{x \in S_{m}} N_{2}(G, \varepsilon), \quad \varepsilon > 0.$$ 

Let $H_{s}$ be the reproducing kernel Hilbert space of $K_{\sigma,s}$ and $B_{H_{s}}$ be the unit ball in $H_{s}$. The following Lemmas 16 and 17 can be easily deduced from 26, Theorem 2.1 and 27, respectively.

**Lemma 16:** Let $0 < \sigma \leq 1$, $X \subset \mathbb{R}^{d}$ be a compact subset with nonempty interior. Then for all $0 < p \leq 2$ and all $\nu > 0$, there exists a constant $C_{p,\nu,d,s} > 0$ independent of $\sigma$ such that for all $\varepsilon > 0$, we have

$$\log N_{2}(B_{H_{s}}, \varepsilon) \leq C_{p,\nu,d,s}(p/2 - 1)(1 + \nu)d\varepsilon^{-p}.$$ 

**Lemma 17:** Let $F$ be a class of measurable functions on $Z$. Assume that there are constants $B, c > 0$ and $\alpha \in [0, 1]$ such that $\|f_{\alpha}\|_{m} \leq B$ and $E_{f} \leq c|E_{f}|^{\alpha}$ for every $f \in F$. If for some $a > 0$ and $p \in (0, 2),$

$$\log N_{2}(F, \varepsilon) \leq a\varepsilon^{-p}, \quad \forall \varepsilon > 0,$$

then there exists a constant $c_{p}^{f}$ depending only on $p$ such that for any $t > 0$, with probability at least $1 - e^{-t}$, there holds

$$E_{f} - \frac{1}{m} \sum_{i=1}^{m} f(z_{i}) \leq \frac{1}{2}\eta^{1 - \nu}(E_{f})^{\alpha} + c_{p}^{f}\eta^{\nu/2} + 2\left(\frac{ct}{m}\right)^{\frac{1}{2}} + 18Bt/m, \quad \forall f \in F,$$

(23)

where

$$\eta := \max \left\{c^{-2/(2 + p)}\left(\frac{a}{m}\right)^{-2/(2 + p)}, B^{-2/(2 + p)}\left(\frac{a}{m}\right)^{-2/(2 + p)}\right\}.$$ 

The next lemma states a variant of Lemma 4 which can be found in 24.

**Lemma 18:** Let $\xi$ be a random variable on a probability space $Z$ with variance $\gamma^{2}$ satisfying $|\xi - E\xi| \leq M_{\xi}$ for some constant $M_{\xi}$. Then, for any $0 < \delta < 1$, with confidence $1 - \delta$, we have

$$\frac{1}{m} \sum_{i=1}^{m} \xi(z_{i}) - E\xi \leq \frac{2M_{\xi}\log \frac{2}{3\delta}}{3m} + \sqrt{\frac{2\gamma^{2}\log \frac{1}{\delta}}{m}}.$$ 

From the proof of Lemma 9 we can also deduce the following Lemma 19.

**Lemma 19:** Let $\delta, s, n \in \mathbb{N}$. Then with confidence at least $1 - 2\exp\{-cn\sigma^{2d}\}$, there exists a $f_{0} \in H_{s,\nu,n}$ such that

$$\|f_{0} - f_{\rho}\|^{2} + \lambda\Omega(f_{0}) \leq C(\omega_{s,d}(f_{\rho}, \sigma)^{2} + \sigma^{2d} + \lambda/n),$$

where $C$ is a constant depending only on $d, s$ and $M$.

**Proof:** Let

$$f_{0} = \sum_{i=1}^{n} a_{i}K_{\sigma,s}(x - \eta_{i}) = \sum_{i=1}^{n} w_{i}P_{i}(\eta_{i})K_{\sigma,s}(x - \eta_{i}),$$

where $\{w_{i}\}_{i=1}^{n}$ and $P_{i}$ are the same as those in the proof of Lemma 9. Then, it has already been proved that

$$\|f_{\rho} - f_{0}\|_{p} \leq C(\omega_{s,d}(f_{\rho}, \sigma) + \sigma^{d}).$$

Furthermore, it can be deduced from Lemma 8 and 18 by taking $f = f_{\rho}$ that

$$\Omega(f_{0}) = \sum_{i=1}^{n} |w_{i}|^{2}P_{i}(\eta_{i})^{2} \leq \|f_{\rho}\|_{p}^{2} \sum_{i=1}^{n} |w_{i}|^{2} \leq C/n.$$ 

This finishes the proof of Lemma 19.

Now we proceed the proof of Theorem 3.

**Proof of Theorem 3** Let $f_{s,\sigma,s,\lambda,n}$ and $f_{0}$ be defined as in 12 and Lemma 19 respectively. Define

$$D := E(f_{0}) - E(f_{\rho}) + \lambda\Omega(f_{0})$$

and

$$S := E_{x}(f_{0}) - E_{x}(f_{\rho}) + E(\sigma_{M}f_{s,\sigma,s,\lambda,n}) - E(\sigma_{M}f_{s,\sigma,s,\lambda,n}),$$

where $E_{x}(f) = \frac{1}{m} \sum_{i=1}^{m} (y_{i} - f(x_{i}))^{2}$. Then, it is easy to check that

$$E(\sigma_{M}f_{s,\sigma,s,\lambda,n}) - E(f_{\rho}) \leq D + S.$$ 

(25)

As $f_{\rho} \in F_{\rho}$, it follows from Lemma 19 that with confidence at least $1 - 2\exp\{-cn\sigma^{2d}\}$ (with respect to $\mu^{n}$), there holds

$$D \leq C(\sigma^{2d} + \gamma^{2d} + \lambda/n).$$ 

(26)

Upon using the short hand notations

$$S_{1} := \{E_{x}(f_{0}) - E_{x}(f_{\rho})\} - \{E(\sigma) - E(f_{\rho})\}$$

and

$$S_{2} := \{E(\sigma_{M}f_{s,\sigma,s,\lambda,n}) - \sigma_{M}f_{s,\sigma,s,\lambda,n}\} - \{E_{x}(\sigma_{M}f_{s,\sigma,s,\lambda,n}) - E_{x}(f_{\rho})\},$$

we have

$$S = S_{1} + S_{2}.$$ 

(27)

We first turn to bound $S_{1}$. Let the random variable $\xi$ on $Z$ be defined by

$$\xi(z) = (y - f_{0}(x))^{2} - (y - f_{\rho}(x))^{2}, \quad z = (x, y) \in Z.$$ 

Since $|f_{\rho}(x)| \leq M$ and

$$|f_{0}| \leq \sum_{i=1}^{n} |w_{i}| |P_{i}(\eta_{i})||K_{\sigma,s}(\eta_{i}, x)| \leq \|f_{\rho}\| \sum_{i=1}^{n} |w_{i}| \leq CM,$$

hold almost everywhere, we have

$$\|\xi(z)\| = (f_{\rho}(x) - f_{0}(x))(2y - f_{\rho}(x) - f_{0}(x)) \leq (M + CM)(3M + CM) \leq M_{\xi} := (3M + CM)^{2}$$

and almost surely

$$\|\xi - E\xi\| \leq 2M_{\xi}.$$ 

Moreover, we have

$$E(\xi^{2}) = \int_{Z} (f_{0}(x) + f_{\rho}(x) - 2y)(f_{0}(x) - f_{\rho}(x))^{2} dp$$

$$\leq M_{\xi}\|f_{\rho} - f_{0}\|^{2},$$

which implies that the variance $\gamma^{2}$ of $\xi$ can be bounded as

$$\gamma^{2} \leq E(\xi^{2}) \leq M_{\xi}D.$$ 

Now applying Lemma 18 we obtain

$$S_{1} \leq \frac{4M_{\xi}\log \frac{2}{3\delta}}{3m} + \sqrt{\frac{2M_{\xi}D\log \frac{2}{3\delta}}{m}}$$

$$\leq \frac{7(3M + CM)^{2}\log \frac{2}{3\delta}}{3m} + \frac{1}{2}D$$ 

(28)
holds with confidence $1 - \frac{1}{2}$ (with respect to $\rho^{m}$).

To bound $S_2$, we need apply Lemma 17 to the set $G_R$, where
\[ G_R := \{ (y - \pi_M f(x))^2 - (y - f_\rho(x))^2 : f \in B_R \} \]
and
\[ B_R := \left\{ f = \sum_{i=1}^n b_i K_{\sigma,s}(\eta_i, x) : \sum_{i=1}^n |b_i|^2 \leq R \right\}. \]

Each function $g \in G_R$ has the form
\[ g(z) = (y - \pi_M f(x))^2 - (y - f_\rho(x))^2, \quad f \in B_R \]
and is automatically a function on $Z$. Hence
\[ E_g = E(f) - E(f_\rho) = \|\pi_M f - f_\rho\|^2_\rho \]
and
\[ \frac{1}{m} \sum_{i=1}^m g(z_i) = \mathcal{E}_g(\pi_M f) - \mathcal{E}_g(f_\rho), \]
where $z_i := (x_i, y_i)$. Observe that
\[ g(z) = (\pi_M f(x) - f_\rho(x))(\pi_M f(x) - y) + (f_\rho(x) - y)). \]
Therefore,
\[ |g(z)| \leq 8M^2 \]
and
\[ E_g^2 = \int_Z (2y - \pi_M f(x) - f_\rho(x))^2(\pi_M f(x) - f_\rho(x))^2 d\rho \leq 16M^2 \|

For $g_1, g_2 \in F_{R_{\delta}}$ and arbitrary $m \in \mathbb{N}$, we have
\[ \left( \frac{1}{m} \sum_{i=1}^m (g_1(z_i) - g_2(z_i))^2 \right)^{1/2} \leq \left( \frac{4M^2}{m} \sum_{i=1}^m (f_1(x_i) - f_2(x_i))^2 \right)^{1/2}. \]

It follows that
\[ \mathcal{N}_{2,\varepsilon}(G_R, \varepsilon) \leq \mathcal{N}_{2,\varepsilon}(B_R, \frac{\varepsilon}{4M}) \leq \mathcal{N}_{2,\varepsilon}(B_1, \frac{\varepsilon}{4M R}), \]
which together with Lemma 16 implies
\[ \log \mathcal{N}_{2,\varepsilon}(G_R, \varepsilon) \leq C_{p,\mu,\sigma} \frac{1}{\varepsilon} \log(4) \hat{c} m \log(4) \|

By Lemma 17 with $B = c = 16M^2$, $\alpha = 1$ and $\alpha = C_{p,\mu,\sigma} \frac{1}{\varepsilon} \log(4 \|

Now we turn to estimate $R$. It follows form the definition of $f_{\pi,\sigma,s,\lambda,n}$ that
\[ \mathcal{M}(f_{\pi_\sigma,s,\lambda,n}) \leq \mathcal{E}_\pi(0) + \lambda \cdot 0 \leq M^2. \]

Thus, we obtain that for arbitrary $0 < \delta \leq 2$ and arbitrary $\nu > 0$, there exists a constant $C$ depending only on $d$, $\nu$, $p$ and $M$ such that
\[ S_2 \leq \frac{1}{2} \{ \mathcal{E}(\pi_M f_{\pi,\sigma,s,\lambda,n}) - \mathcal{E}(f_\rho) \} + C \log \frac{4}{\delta} m^{-\frac{1}{2}} \sigma \left( \frac{(p-2)(p+4)\delta}{1-2\rho m^2} \lambda \right) \]
with confidence at least $1 - \frac{\delta}{2}$ (with respect to $\rho^m$).

From (25) to (29), we obtain
\[ \mathcal{E}(\pi_M f_{\pi,\sigma,s,\lambda,n}) - \mathcal{E}(f_\rho) \leq C \left( \frac{\sigma^2 + \sigma^2d + \lambda^2}{3m} \right) \]
holds with confidence at least $(1 - \delta) \times (1 - 2 \exp(-cn^2d))$ (with respect to $\rho^m \times m^2$).

Set $\sigma = m^{-\frac{\delta}{2(2d+2)}}$, $n = m^{\frac{\delta}{2d+2}}$, $\lambda = m^{-\frac{\delta}{2d+2}}$, and
\[ P = \frac{2d + 2 \varepsilon (2r + d) - 2(1 + \nu) + 2(2r + d)\varepsilon (1 + \nu) d}{2(2r + d)(2a + d + 2\varepsilon c - \varepsilon) + 2r - (1 + \nu) d}. \]

Since $r \geq d/2$, it is easy to check that $\nu > 0$, and $0 < p \leq 2$. Then, we get
\[ \mathcal{E}(\pi_M f_{\pi,\sigma,s,\lambda,n}) - \mathcal{E}(f_\rho) \leq \frac{C^2}{m^{-\frac{\delta}{2d+2}} \varepsilon} \log 4 \delta. \]

Noting further that $r \leq d$, we obtain
\[ \mathcal{E}(\pi_M f_{\pi,\sigma,s,\lambda,n}) - \mathcal{E}(f_\rho) \leq C m^{-\frac{\delta}{2d+2}} \varepsilon \log 4 \delta. \]

Noticing the identity
\[ E_{\rho^m}(\mathcal{E}(f_\rho) - \mathcal{E}(f_{\pi,\lambda,n})) = \int_0^\infty P^m \{ \mathcal{E}(f_\rho) - \mathcal{E}(f_{\pi,\lambda,n}) > \varepsilon \} d\varepsilon, \]
direct computation yields the upper bound of (13). The lower bound can be found in [8, Chap.3]. This finishes the proof of Theorem 3.

VI. CONCLUSIONS

The ELM-like learning provides a powerful computational burden reduction technique that adjusts only the output connection. Numerous experiments and applications have demonstrated the effectiveness and efficiency of ELM. The aim of our study is to provide theoretical fundamentals of it. After analyzing the pros and cons of ELM, we found that the theoretical performance of ELM depends heavily on the activation function and randomness mechanism. In the previous cousin paper [18], we have provided the advantages of ELM in theory, that is, with appropriately selected activation function, ELM
reduces the computation burden without sacrificing the generalization capability in the expectation sense. In this paper, we discussed certain disadvantages of ELM. Via rigorous proof, we found that ELM suffered from both the uncertainty and generalization degradation problem. Indeed, we proved that, for the widely used Gaussian-type activation function, ELM degraded the generalization capability. To facilitate the use of ELM, some remedies of the aforementioned two problem are also recommended. That is, multiple times trials can avoid the uncertainty problem and the $l^2$ coefficient regularization technique can essentially improve the generalization capability of ELM. All these results reveal the essential characteristics of ELM learning and give a feasible guidance concerning how to use ELM.

We conclude this paper with a crucial question about ELM learning.

**Question 1**: As is shown in [18] and the current paper, the performance of ELM depends heavily on the activation function. For appropriately selected activation function, ELM does not degrade the generalization capability, while there also exists an activation function such that the degradation exists. As it is impossible to enumerate all the activation functions and study the generalization capabilities of the corresponding ELM, we are asked for a general condition on the activation function, under which the corresponding ELM degrade (or doesn’t degrade) the generalization capability. In other words, we are interested in a criterion to classify the activation functions into two classes. With the first class, ELM degrades the generalization capability and with the other class, ELM does not degrades the generalization capability. We will keep working on this interesting project, and report our progress in a future publication.
