Neutrino Mass Matrix
Out of Up-Quark Masses Only

Abstract

Under the assumption of symmetric four zero texture for fermion mass matrices in $SO(10)$ model, the neutrino Dirac mass matrix is derived from the up-quark mass matrix. By adjusting two scales of the Majorana mass sector, we can derive observed neutrino two large mixing angles very naturally. It is indeed remarkable that all the masses and mixings of neutrinos are expressed in terms of only three known parameters, $m_t, m_c, m_u$. A typical example of our model is

$$\tan^2 2\theta_{\tau\mu} = \frac{4}{(1 - \frac{m_c}{\sqrt{m_u m_t}})^2}.$$
Recent neutrino experiments by Super-Kamiokande [1, 2] and SNO [3] have confirmed neutrino oscillations with large mixing angles:

$$\sin^2 2\theta_{\text{atm}} > 0.83 \text{ (99\% C.L.)},$$

$$\tan^2 \theta_{\text{sol}} = 0.24 - 0.89 \text{ (99.73\% C.L.)},$$

with mass squared differences of

$$\Delta m_{\text{atm}}^2 \sim 2.5 \times 10^{-3} \text{ eV}^2,$$

$$\Delta m_{\text{sol}}^2 \sim 5 \times 10^{-5} \text{ eV}^2.$$  

The neutrino mixing angles are expressed by MNS matrix [4] which is written as

$$V_{\text{MNS}} = U^\dagger_l U^\nu,$$  

with $U_l$ and $U^\nu$ being the unitary matrices which diagonalize the $3 \times 3$ charged lepton and neutrino mass matrices, $M_l$ and $M^\nu$,

$$U^\dagger_l M_l U_l = \text{diag}(m_{e}^2, m_{\mu}^2, m_{\tau}^2),$$

$$U^\dagger^\nu M^\nu U^\nu = \text{diag}(m_{\nu_e}^2, m_{\nu_\mu}^2, m_{\nu_\tau}^2),$$

respectively. Here the left-handed neutrino mass matrix is expressed in terms of right-handed Majorana neutrino mass matrix, $M_R$, and Dirac neutrino mass matrix, $M_{\nu_D}$,

$$M^\nu = M^T_{\nu_D} M^{-1}_R M_{\nu_D}.$$  

If we restrict ourselves to the case in which such large mixings are naturally derived without fine tuning, the origin of each of the large mixing angles, $\theta_{\mu\tau}$ and $\theta_{e\mu}$, must be due to either $M^\nu$ or $M_l$.

In this paper, we show that these two large mixing angles can be derived from symmetric four zero texture within the $SO(10)$ GUT framework. We assume the following textures for up- and down-type quark mass matrices at the GUT
scale \( \| \), \( \|\)

\[
M_D = \begin{pmatrix}
0 & \sqrt{\frac{m_u m_c}{m_b - m_d}} & 0 \\
\sqrt{\frac{m_d m_s}{m_b - m_d}} & m_t & \sqrt{\frac{m_d}{m_b - m_d}} \\
0 & \sqrt{\frac{m_b}{m_b - m_d}} & 0
\end{pmatrix}
\]

\[
\approx m_b \begin{pmatrix}
0 & \sqrt{\frac{m_d m_s}{m_b - m_d}} & 0 \\
\sqrt{\frac{m_d}{m_b}} & m_t & \sqrt{\frac{m_b}{m_b - m_d}} \\
0 & \frac{m_d}{m_b} & 1
\end{pmatrix}
\]  \(\text{(8)}\)

\[
M_U \approx m_t \begin{pmatrix}
0 & \sqrt{\frac{m_u m_c}{m_t}} & 0 \\
\sqrt{\frac{m_u}{m_t}} & m_e & \sqrt{\frac{m_t}{m_t}} \\
0 & \sqrt{\frac{m_t}{m_t}} & 1
\end{pmatrix} \equiv m_t \begin{pmatrix}
0 & a & 0 \\
a & b & c \\
0 & c & 1
\end{pmatrix}.
\]  \(\text{(9)}\)

As for \(M_D\) it is well known that each elements of \(M_U\) and \(M_D\) is dominated by the contriubtion either from \(10\) or \(126\) Higgs fields, where the ratio of Yukawa couplings of charged lepton to down quark are 1 or \(-3\), respectively. More concretely the following option for \(M_D\) (Georgi-Jarlskog type \[6\])

\[
M_D = \begin{pmatrix}
0 & 10 & 0 \\
10 & 126 & 10 \\
0 & 10 & 10
\end{pmatrix},
\]  \(\text{(10)}\)

is known to reproduce very beautifully all the experimental data of \(m_\tau, m_\mu, m_e\) as well as \(m_b, m_s, m_d\) \[4, 8\]. On the other hand, \(M_U\) is related to \(M_{\nu_D}\), which is not directly connected to neutrino experiments no definite configuration has been found so far. Here we show the following option reproduces two large mixings at the same time,

\[
M_U = \begin{pmatrix}
0 & 126 & 0 \\
126 & 10 & 10 \\
0 & 10 & 126
\end{pmatrix},
\]  \(\text{(11)}\)

\footnote{Here we neglect the CP phases, since they have little effect on the final result. The simple expressions Eq. (8) and (9) are derived by using \(m_u << m_c << m_t, m_d << m_s << m_b\).}
which uniquely determines neutrino Dirac mass matrix as

\[ M_{\nu D} = m_t \begin{pmatrix} 0 & -3a & 0 \\ -3a & b & c \\ 0 & c & -3 \end{pmatrix}. \]  

(12)

For the right-handed Majorana mass matrix, to which only 126 Higgs field couples, we assume the following option consistently with \( M_U \):

\[ M_R \equiv m_R \begin{pmatrix} 0 & r & 0 \\ r & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}. \]  

(13)

Then from Eq. (7), we get

\[ M_\nu = m_t \begin{pmatrix} 0 & \frac{a^2}{r} & \frac{c^2}{r} & 0 \\ \frac{a^2}{r} & \frac{-2ab}{3r} + \frac{c^2}{9} & -\frac{c}{3}(\frac{a}{r} + 1) \\ \frac{c^2}{r} & \frac{-c}{3}(\frac{a}{r} + 1) & 1 \end{pmatrix} \frac{9m_t^2}{m_R}. \]  

(14)

Since the order of the parameters in the above Eq. (14) are \( a << b \leq c << 1 \), we recognize that the first term of the 3-2 element, \(-\frac{3ac}{r}\), must be of order 1 in order to get large mixing angle \( \theta_{\mu\tau} \), so we here take

\[ r \simeq \frac{ac}{3} \simeq \sqrt{\frac{m_t^2 m_c}{3m_t^2}} \sim 10^{-7}. \]  

(15)

This is almost the same situation as discussed by Kugo, Yoshioka and one of the present authors [9]. This tiny value of \( r \) is very welcome [9]; the right-handed Majorana mass of the third generation must become of the order of GUT scale while those of the first and second generations are of order \( 10^8 \) GeV. This is quite favorable for the GUT scenario to reproduce the bottom-tau mass ratio.

Up to here the situation is quite trivial in a sense; one arbitrary parameter \( r \) has been chosen so as to reproduce the large mixing angle \( \theta_{\mu\tau} \). Now the problem is whether it naturally reproduces another mixing angle \( \theta_{e\mu} \). At this stage we have no arbitrary parameter to adjust the mass ratios or mixing angles. Under such
condition, $M_\nu$ is approximately written as

$$M_\nu = \begin{pmatrix} 0 & -\frac{3a}{c} & 0 \\ -\frac{3a}{c} & \frac{2b}{c} & -1 \\ 0 & -1 & 1 \end{pmatrix} \frac{9m_l^2}{m_R} \equiv \begin{pmatrix} 0 & \beta & 0 \\ \beta & \alpha & -1 \\ 0 & -1 & 1 \end{pmatrix} \frac{9m_l^2}{m_R},$$

(16)

with $\alpha = \frac{2b}{c} = \frac{2m_c}{m_u m_u}$ and $\beta = -\frac{3a}{c} = -3\sqrt{\frac{m_c}{m_t}}$. Since $\beta << \alpha \sim 1$, we first diagonalize the $2 \times 2$ matrix of the 2-3 block of Eq. (16) by rotating the following angle

$$\tan^2 2\theta_{\mu\tau} = \frac{4}{(1 - \alpha)^2},$$

(17)

through which $M_\nu$ is deformed as follows

$$\begin{pmatrix} 0 & \beta & 0 \\ \beta & \alpha & -1 \\ 0 & -1 & 1 \end{pmatrix} \rightarrow \begin{pmatrix} 0 & \beta \cos \theta_{\mu\tau} & \beta \sin \theta_{\mu\tau} \\ \beta \cos \theta_{\mu\tau} & \lambda_2 & 0 \\ \beta \sin \theta_{\mu\tau} & 0 & \lambda_3 \end{pmatrix},$$

(18)

with

$$\lambda_3 = \frac{\alpha + 1 + \sqrt{(\alpha - 1)^2 + 4}}{2} \approx \lambda_{\tau},$$

(19)

$$\lambda_2 = \frac{\alpha + 1 - \sqrt{(\alpha - 1)^2 + 4}}{2}.\quad (20)$$

Then we further diagonalize the $2 \times 2$ matrix of the 1-2 block of Eq. (18) by rotating $\theta_{e\mu}$:

$$M_\nu \rightarrow \begin{pmatrix} \lambda_e & 0 & \beta \sin \theta_{\mu\tau} \cos \theta_{e\mu} \\ 0 & \lambda_\mu & \beta \sin \theta_{\mu\tau} \sin \theta_{e\mu} \\ \beta \sin \theta_{\mu\tau} \cos \theta_{e\mu} & \beta \sin \theta_{\mu\tau} \sin \theta_{e\mu} & \lambda_{\tau} \end{pmatrix},$$

(21)

with the rotating angle

$$\tan^2 2\theta_{e\mu} = \left(\frac{2\beta \cos \theta_{\mu\tau}}{\lambda_2}\right)^2,$$

(22)

and mass eigenvalues

$$\lambda_\mu = \frac{\lambda_2 + \sqrt{\lambda_2^2 + 4\beta^2 \cos^2 \theta_{\mu\tau}}}{2},$$

(23)

$$\lambda_e = \frac{\lambda_2 - \sqrt{\lambda_2^2 + 4\beta^2 \cos^2 \theta_{\mu\tau}}}{2}.\quad (24)$$
Finally we get the following approximate form for the rest small rotating angle,

\[ \sin \theta_{e3} = \frac{2\beta \sin \theta_{\mu\tau} \cos \theta_{e\mu}}{\lambda_{\tau}}. \] (25)

Leaving details in a separate paper [10], we demonstrate how we can predict neutrino masses and mixings; all the neutrino information are determined in terms of \( m_u, m_c, m_t \) as

\[ \tan^2 2\theta_{\mu\tau} \simeq \frac{1}{(1 - \frac{2m_c}{\sqrt{m_u m_t}})^2}, \] (26)

\[ \tan^2 2\theta_{e\mu} \simeq \frac{9m_c}{m_t(1 - \frac{2m_c}{\sqrt{m_u m_t}})^2}, \] (27)

\[ \sin \theta_{e3} \simeq -3\sqrt{\frac{m_c}{m_t}} \sin \theta_{\mu\tau} \cos \theta_{e\mu}, \] (28)

from which the following equations are derived

\[ \tan^2 2\theta_{e\mu} \simeq \frac{9m_c}{m_t} \tan^2 2\theta_{\mu\tau}, \quad \sin^2 \theta_{e3} \simeq \frac{9m_c}{m_t} \sin^2 \theta_{\mu\tau} \cos^2 \theta_{e\mu}. \] (29)

This indicates that \( \tan^2 2\theta_{e\mu} \) is smaller by a factor \( \frac{9m_c}{m_t} \) than \( \tan^2 2\theta_{\mu\tau} \). Interesting enough is that once we know the atmospheric and solar neutrino experiments, \( U_{e3} \) is predicted without any ambiguity coming from the up-quark masses at GUT scale;

\[ \sin^2 \theta_{e3} \simeq \frac{\tan^2 2\theta_{e\mu}}{\tan^2 2\theta_{\mu\tau}} \cdot \sin^2 \theta_{\mu\tau} \cos^2 \theta_{e\mu}, \] (30)

which is independent of the uncertainty especially coming from the value, \( m_t \), at GUT scale.

Next the neutrino masses are given by

\[ m_{\nu_{\tau}} \simeq \lambda_{\tau} \cdot \frac{m_t^2}{m_R}, \quad m_{\nu_{\mu}} \simeq \lambda_{\mu} \cdot \frac{m_t^2}{m_R}, \quad m_{\nu_{e}} \simeq \lambda_{e} \cdot \frac{m_t^2}{m_R}, \] (31)

where the renormalization factor (\( \sim \frac{1}{3} \)) has been taken account to estimate the lepton masses at low energy scale. Since \( \lambda_{\mu} << \lambda_{\tau} \sim O(1) \), this indeed yields \( m_R \sim 10^{16} \text{ GeV} \), as many people require. On the other hand, \( m_{\nu_{\mu}} \) is expected to become almost of the same order to \( m_{\nu_{e}} \) as is seen from Eq. (31).

Let us make some numerical calculation. We take the values of \( m_t, m_c, m_u \) at GUT scale obtained by Fusaoka and Koinde [11]:

\[ m_u = 1.04^{+0.19}_{-0.20} \text{ MeV,} \] (32)
\[ m_c = 302^{+25}_{-27} \text{ MeV}, \quad (33) \]
\[ m_t = 129^{+196}_{-40} \text{ GeV}. \quad (34) \]

Among them \( m_t \) is the most sensitive parameter. Fig. 1 and Fig. 2 show the dependence of the resultant values of \( \theta_{\mu\tau} \) and \( \theta_{e\mu} \) on \( m_t \), respectively. From Fig. 1 \( m_t \) is found to be larger than 90 GeV and from Fig. 2 the lower bound is \( m_t = 170 \) GeV. With this bound for \( m_t \) (170 – 320 GeV) we can predict the values of \( U_{e3} \),

\[ U_{e3} \sim 0.03 - 0.045. \quad (35) \]

from Fig. 3. We hope this can be checked by experiment in near future JHF-Kamioka long-base line \([12]\), the sensitivity of which is reported as \( |U_{e3}| \sim 0.04 \) at 90 \( \% \) C.L.. If we further expect Hyper-Kamiokande (\( |U_{e3}| < 10^{-2} \) \([13]\), we can completely check whether such symmetric texture model can survive or not. In conclusion we list a set of typical values of neutrino masses and mixings at \( m_t \sim 240 \) GeV;

\[ \sin^2 2\theta_{\mu\tau} \sim 0.95 - 1, \quad (36) \]
\[ \tan^2 \theta_{e\mu} \sim 0.23 - 0.6, \quad (37) \]
\[ U_{e3} \sim 0.037 - 0.038, \quad (38) \]
\[ m_{\mu\tau} \sim 0.06 - 0.07 \text{ eV}, \quad (39) \]
\[ m_{\nu\mu} \sim 0.003 - 0.006 \text{ eV}, \quad (40) \]
\[ m_{\nu e} \sim 0.0007 - 0.0015 \text{ eV}, \quad (41) \]

with \( m_R = 2 \times 10^{15} \) GeV and \( r m_R = 10^8 \) GeV, which correspond to the Majorana mass for the third generation and those of the second and first generations, respectively.

Remark that, once the scale of right-handed Majorana mass matrix, \( r \), is determined so as for the mixing angle of atmospheric neutrino to become maximal, the same vale \( r \) well reproduces the ratio of the mass differences \( \Delta m_{\mu\tau}^2 \) to \( \Delta m_{e\mu}^2 \).

We add two comments. First, one might suspect that we may always reproduce any desired neutrino mass matrix by adjusting the parameters appearing in \( M_R \), namely we can take \( M_R = M_{\nu D} M^{-1}_\nu M^T_{\nu D} \). However this is not actually true if the mass matrix \( M_U \) is of such hierarchical structure as those coming from the famous
anomalous $U(1)$. We shall show this in a separate paper [10], where other options of Eq. (11) are fully investigated to confirm that only the option adopted in this paper can reproduce the two large mixing angles. Second, our scenario is quite different from those starting from the assumption that the large mixing angles observed in neutrino oscillation data comes from the charged lepton mass matrix; one might predict some relations of neutrino mixing angles to down quark information [14], but we would no more predict the absolute values of neutrino masses, which indeed needs the information of $M_{\nu}$. Our scenario, if it is indeed true, can predict without any ambiguity even for the order-one coefficients. The remarkable results are obtained really thanks to the power of GUT.
