SECANTS OF MINUSCULE AND COMINUSCULE MINIMAL ORBITS

LAURENT MANIVEL AND MATEUSZ MICHALEK

Abstract. We study the geometry of the secant and tangential variety of a cominuscule and minuscule variety, e.g. a Grassmannian or a spinor variety. Using methods inspired by statistics we provide an explicit local isomorphism with a product of an affine space with a variety which is the Zariski closure of the image of a map defined by generalized determinants. In particular, equations of the secant or tangential variety correspond to relations among generalized determinants. We also provide a representation theoretic decomposition of cubics in the ideal of the secant variety of any Grassmannian.

1. Introduction

The aim of the article is to investigate the properties of the secant variety of the minimal orbit in a minuscule and cominuscule representation of a semi-simple complex Lie group. The prototypical examples of such varieties are the Grassmannians. The Grassmannian of $k$ dimensional subspaces of an $n$ dimensional vector space $V$ is the image of the map

\[ \{ \text{nondegenerate } k \times n \text{ matrices} \} \to \mathbb{P}(\bigwedge^k V) \]

\[ M \mapsto [\text{all maximal minors of } M]. \]

Moreover, we can parameterize an affine open chart of the Grassmannian by

\[ \{ k \times (n - k) \text{ matrices} \} \to \mathbb{A}^{\binom{n}{k} - 1} \subset \mathbb{P}(\bigwedge^k V) \]

\[ M \mapsto (\text{all minors of } M). \]

In particular, one can consider the Plücker relations that define the Grassmannian, as quadratic relations among minors, coming from the Laplace expansion of the determinant.

We generalize these classical observations to the tangential and secant variety, by providing analogous local parameterizations. Recall that the tangential variety is the union of all tangent lines to the variety, while the secant variety is the Zariski closure of the union of the bisecant lines. It turns out that the tangential variety is locally isomorphic to a product of an affine space by the Zariski closure of the variety $M$ parameterized by all minors of degree at least two of a generic matrix. The secant variety is locally isomorphic to a product of an affine space by the cone over $M$. In particular, the equations of the tangential (resp. secant) variety correspond to (resp. homogeneous) relations among minors of degree at least 2.

Our method is inspired by the "cumulant trick" coming from statistics. Given probability distributions, the statisticians compute general moments and cumulants. The formulas for those were the inspiration to define two triangular automorphisms of the affine space. This method has had other successful applications [SZ11, MOZ12].

The first author is supported by the Narodowe Centrum Nauki grant UMO-2011/01/N/ST1/05424 "Representation theory and secants of homogeneous varieties".
Furthermore, using generalized determinants, we are able to extend our results to all varieties that are both minuscule and cominuscule obtaining our main theorem. In order to prove our results we present formulas for the generalized determinants for a sum and a generalized Laplace expansion in Lemmas 2.5 and 2.6. The following setting also includes the spinor varieties and the two exceptional Hermitian symmetric spaces. The equations of the secant and tangential variety correspond to the relations among the Pfaffians.

**Main Theorem** (Theorem 3.4). The secant variety of the minimal orbit $Y$ in the projectivization of a minuscule and cominuscule representation can be covered by complements of hyperplane sections that are isomorphic to the product of an affine space of the same dimension as $Y$, by the affine cone over the projective variety parameterized by all generalized determinants of degree strictly greater than one.

Analogously, the tangential variety is locally isomorphic to a product of an affine space by the affine variety parameterized by all generalized determinants of degree strictly greater than one. The inclusion of this variety in the cone over it corresponds exactly to the inclusion of the tangential variety inside the secant.

**Corollary 1.1.** On each of these affine charts, the ideal of the closure of the minimal orbit is given by relations among all generalized determinants, while:

- the secant is defined by the homogeneous relations among those generalized determinants that are of degree strictly greater than one,
- the tangential variety is defined by all the relations among those generalized determinants that are of degree strictly greater than one.

While the ideal of an equivariantly embedded homogeneous variety is always generated by quadrics, in general, the ideal of its secant variety is not known. There are no quadrics vanishing on the secant variety. Although, it is not true that the ideal of the secant of a homogeneous variety is always generated by cubics [Man09], it is expected that this property holds for Grassmannians. We provide an explicit representation theoretic description of cubics in the ideal of any Grassmannian $G(k, n)$. This is related to the plethysm $S^3(\wedge^k)$, which has been computed in [Lit44, CGR]. We present a short proof in the Appendix. An analogous description for the secant of Segre varieties was provided in [LM04] [Theorem 4.7] and the ideal is now known in any degree for the secant variety of a Segre-Veronese variety [Rai12].

There are many motivations to study secant varieties of homogeneous varieties coming both from pure and applied mathematics. Homogeneous varieties come with a preferred embedding, thus the secant and tangential varieties are intrinsic objects. Their geometry is very interesting - a classical reference is [Zak05], however the topic has been studied by many other authors - please consult [Lan12] and references therein. Still, the increasing interest in the topic is strongly motivated by possible applications in computer sciences, image processing, statistics etc. This is related to the problem of determining ranks (or border ranks) of tensors.

The Segre, Veronese embeddings of projective spaces, as well as the Plücker embeddings of Grassmannians, are of particular interest as they correspond to general, symmetric, and skew-symmetric tensors. While the secant and tangential variety of the Segre-Veronese embeddings is well described [Rai12, OR11], the problem for Grassmannians is wide open. The description for the secant of $G(3, n)$ was provided in [LW09]. In general, we present an easy
method to derive the description of the secant of $G(k, n)$, by the description for $G(k, 3k)$ in Proposition 5.7. In [LOT11] one can find a set of equations, so-called skew-flattenings, that define the first and second secant variety on an open subset. In [DKT11, Dra13] one can find very nice results concerning bounds for the degree of equations that cut out the secant variety set-theoretically. The study of relations among minors is also an interesting, difficult topic [BCV13].

2. Generalized determinants

2.1. Minuscule and cominuscule representations. Let $\mathfrak{g}$ be the Lie algebra of a semisimple complex Lie group $G$. By choosing a Cartan subalgebra $\mathfrak{h}$ we obtain a decomposition $\mathfrak{g} = \mathfrak{h} \oplus \bigoplus_{\beta \in R} \mathfrak{g}_\beta$, where $R$ is the set of roots and the $\mathfrak{g}_\beta$ are the root spaces. By fixing a Weyl chamber, we obtain a basis of the root system, made of the simple roots $\alpha_1, \ldots, \alpha_n$.

Let $\lambda$ be a minuscule and cominuscule dominant weight. In particular $\lambda$ is a fundamental weight $\omega_{i_0}$, corresponding to the simple root $\alpha_{i_0}$. We get a decomposition $\mathfrak{g} = \mathfrak{n} \oplus \mathfrak{p}$, where $\mathfrak{n}$ is the sum of the root spaces $\mathfrak{g}_\beta$ where $\beta$ has negative coefficient on $\alpha_{i_0}$ when expressed as a linear combination of the simple roots. We denote by $B$ the set of these roots. The parabolic subalgebra $\mathfrak{p}$ is the sum of the Cartan subalgebra with the other root spaces.

Let $V_\lambda$ be the minuscule and cominuscule irreducible representation with highest weight $\lambda$. Its weight decomposition is $V_\lambda = \bigoplus_{w \in F} W_w$, where $F$ is the set of weights appearing in $V_\lambda$. Since $\lambda$ is minuscule $F$ is the orbit of $\lambda$ under the Weyl group action, and $\dim W_w = 1$ for each $w$ in $F$. By choosing a non zero vector $v_w \in W_w$ we obtain an isomorphism $i_w : W_w \cong \mathbb{C}$. We also define the projection $\pi_w' : V_\lambda \to W_w$ with respect to the direct sum decomposition, and the composition $\pi_w = i_w \circ \pi_w'$.

To simplify the notation we define the degree $d(\alpha) = \langle \alpha, \omega_{i_0}^\vee \rangle$, where $\omega_{i_0}^\vee$ is the corresponding fundamental coweight. In particular, for any $b \in B$ we have $d(b) = 1$. Each element $f \in F$ can be written as $\lambda$ plus elements of $B$. Such presentation may be not unique, but the number of elements from $B$ is fixed and equals $d(f - \lambda)$. Moreover, among elements from $\lambda - F$, the maximal degree is $d_{\max} = \langle \lambda - w_0(\lambda), \omega_{i_0}^\vee \rangle$, since the lowest weight is the image of $\lambda$ by the maximal length element $w_0$ of the Weyl group.

There are two infinite series of minuscule and cominuscule representations $V$ of simple complex Lie groups $G$, and two exceptional examples. They are presented in the table below, with the corresponding values of $d_{\max}$. The main geometric object we are interested in is the minimal orbit $Y$ in $\mathbb{P}(V)$.

| $G$   | $V$  | $d_{\max}$ | $Y$                      |
|-------|------|-------------|--------------------------|
| $SL_n$ | $\wedge^k \mathbb{C}^n$ | $k$ | $G(k, n)$ | Grassmannian |
| $Spin_{2n}$ | $\Delta$ | $n$ | $S_{2n}$ | Spinor variety |
| $E_6$ | $V_{\omega_1}$ | $2$ | $\mathbb{O} \wedge^2 \mathbb{C}$ | Cayley plane |
| $E_7$ | $V_{\omega_7}$ | $3$ | $G_2(\mathbb{O}^3, \mathbb{O}^6)$ | Freudenthal variety |

For Grassmannians we suppose that $k \leq n - k$. We will not say much about the two exceptional cases. The secant variety of the Cayley plane is degenerate, it is the famous Cartan cubic hypersurface of this Severi variety. The secant of the Freudenthal variety is non degenerate, in fact it is equal to the whole ambient projective space, and the tangential variety is a quartic hypersurface.

2.2. Some properties of generalized determinants. Let us recall the construction of the generalized determinant from [FZ00, GSS7]. Fix a weight $w \in F$. Define $\det_w : n \to \mathbb{C}$
by (cf. diagram 2.1)

\[ \det_w(n) = \pi_w(\exp(n)v_\lambda). \]

Let us make the previous construction more explicit. Let \( M := U(g) \otimes_{U(b)} C v_\lambda \) be the Verma module, where \( b \subset g \) is the Borel subalgebra and \( U \) denotes the universal enveloping algebra. We know by the Poincaré-Birkhoff-Witt theorem that \( M = \mathbb{C}[\langle X_b \rangle_{b \in R_-}]v_\lambda \), where \( R_- \) is the set of negative roots. Moreover, \( V_\lambda = M_\lambda / K_\lambda \), for \( K_\lambda \) the unique maximal submodule. In our case \( K_\lambda \) is generated by relations \( X_\beta v_\lambda = 0 \) for \( \beta \in R_- \) such that \( \langle \beta, \omega^\vee_i \rangle = 0 \), and \( X_{a_i}^2 v_\lambda = 0 \) [Dix77].

Notice that so far we have not used the cominuscule assumption. This exactly means that \( n \) is a commutative subalgebra of \( g \). This allows us to consider the variables \( X_\beta \) for \( \beta \in B \) as commutative, and treat the \( n \) action on the Verma module just as multiplication of polynomials. Once \( v_\lambda \) is fixed we may define \( v_w \) as follows. For \( w = \lambda + \beta \) of degree one, it is natural to define \( v_w \) as the class of \( X_\beta v_\lambda \) in \( V_\lambda \). For \( w \) of higher degree, we fix one choice of decomposition \( w = \lambda + \sum_{\beta \in B_w} \beta \), where \( B_w \subset B \). Then we set

\[ v_w = ( \prod_{\beta \in B_w} X_\beta ) v_\lambda. \]

As for \( d(w) \geq 2 \) there may be several possible choices, it is convenient to consider the following compatibility constants.

**Definition 2.1** \((m(w_1, \ldots, w_l))\). For any \( w_1, \ldots, w_l \in F - \{ \lambda \} \) such that \( \lambda + \sum_{i=1}^l w_i \in F \), we define \( m(w_1, \ldots, w_l) \in \mathbb{C} \) by the equation

\[ m(w_1, \ldots, w_l)(\prod_{i=1}^l \prod_{\beta \in B_{w_i}} X_\beta)v_\lambda = ( \prod_{\beta \in B_{\sum_{i=1}^l w_i}} X_\beta)v_\lambda. \]

**Lemma 2.2** (Multiplicative decomposition of compatibility constants). Consider \( \gamma_1, \ldots, \gamma_k \in F - \{ \lambda \} \) with \( \gamma_i = \sum_{j=1}^{a_i} \delta^i_j \), \( \delta^i_j \in F - \{ \lambda \} \), such that \( \lambda + \sum_{j=1}^k \gamma_j \in F \). Then we have

\[ m(\delta^1_1, \ldots, \delta^1_{a_1}, \delta^2_1, \ldots, \delta^k_{a_k}) = m(\gamma_1, \ldots, \gamma_k) \prod_{i=1}^k m(\delta^i_1, \ldots, \delta^i_{a_i}). \]

**Proof.** Let \( \gamma = \gamma_1 + \cdots + \gamma_k \). The definition of the compatibility constants implies that

\[ m(\gamma_1, \ldots, \gamma_k)(\prod_{i=1}^k m(\delta^i_1, \ldots, \delta^i_{a_i})(\prod_{1,j} \prod_{\beta \in B_{\delta^i_j}} X_\beta))v_\lambda = m(\gamma_1, \ldots, \gamma_k)(\prod_{i=1}^k \prod_{\beta \in B_{\gamma_i}} X_\beta)v_\lambda = (\prod_{\beta \in B_{\gamma}} X_\beta)v_\lambda = m(\delta^1_1, \ldots, \delta^1_{a_1}, \delta^2_1, \ldots, \delta^k_{a_k})(\prod_{1,j} \prod_{\beta \in B_{\delta^i_j}} X_\beta)v_\lambda, \]

hence the claim. \( \square \)
Let us now consider the minimal orbit $Y_\lambda = g[v_\lambda] \subset \mathbb{P}(V_\lambda)$. There is a commutative diagram:

\begin{equation}
\begin{array}{ccc}
G & \xrightarrow{f} & GL(V_\lambda) \\
\downarrow & & \downarrow \\
\mathbb{P}(V_\lambda) & \xrightarrow{\pi'_w} & V_\lambda \\
\downarrow & & \downarrow \\
W & \xrightarrow{\text{exp}} & gl(V_\lambda)
\end{array}
\end{equation}

Since $p$ is the tangent space to the orbit of $[v_\lambda]$ and $n$ is transverse to $p$, its image in the orbit is a dense open subset, isomorphic to $n$ since the latter is nilpotent. Therefore, the generalized determinants $\pi_w(\exp(\cdot))v_\lambda$ provide a local parametrization of the orbit of the highest weight vector in the given coordinates. Note that the image of $n$ is contained in the affine subspace $\mathbb{A}_\lambda \subset \mathbb{P}(V_\lambda)$ given by $x_\lambda \neq 0$. We also see that the parametrization can be obtained by $n \ni n_0 \rightarrow \sum_{i=0}^{\infty} \frac{n_i!}{i!} v_\lambda \in V_\lambda$, as sufficiently high power of $n_0$ acts trivially on $v_\lambda$, by the weight computation. We have:

**Corollary 2.3** (cf. [Man09] Sections 2.3, 2.4, 2.5). The ideal of $\mathbb{A}_\lambda \cap Y_\lambda$ is defined by the relations among all the generalized determinants. In particular, for the Grassmannian $G(k,n)$ these are relations among all the minors of a generic $k \times (n-k)$ matrix. For spinor varieties they are the relations between the subpfaffians of a generic skew symmetric matrix.

One of the main aims of this article is to generalize the previous theorem to secant varieties. So far we have obtained a parametrization:

$$p': n \rightarrow \mathbb{A}_\lambda.$$ 

The coordinates of $\mathbb{A}_\lambda$ are $x_b$ for $b \in F$, $b \neq \lambda$. We have $x_b(p'(n_0)) = \det_b(n_0)$. This provides a dominant map to the secant variety:

$$p: \mathbb{C} \times n \times n \rightarrow \mathbb{A}_\lambda,$$

where $x_b(p((t,n_0,n_1))) = t\det_b(n_0) + (1-t)\det_b(n_1)$.

Let us also present further easy results on generalized determinants. We start by providing a precise formula.

**Proposition 2.4.** For any weight $\lambda + \gamma \in F$, we have

$$\det_{\lambda+\gamma}(\sum_{\beta \in B} a_\beta X_\beta) = \sum_{\beta_1 + \cdots + \beta_{d(\gamma)} = \gamma} m(\beta_1, \ldots, \beta_{d(\gamma)}) \prod_{i=1}^{d(\gamma)} a_{\beta_i}.$$

Here we take the sum over decompositions $\beta_1 + \cdots + \beta_{d(\gamma)}$ considered up to permutations. In particular, $\det_{\gamma+\lambda}$ is a homogeneous polynomial in the $a_\beta$'s, of degree $d(\gamma)$.

**Proof.** We simply expand the exponential of $\sum_{\beta \in B} a_\beta X_\beta$, using the usual formula since the $X_\beta$ commute. The factor $d(\gamma)!$ appearing in the expansion simplifies when we consider decompositions of $\gamma$ only up to permutations. \qed

By combining Lemma 2.2 and Proposition 2.4 we deduce the following Lemmas.
Lemma 2.5. For any weight $\lambda + \gamma \in F$, and any $A, B \in n$, we have

$$\det_{\lambda+\gamma}(A + B) = \sum_{\gamma_1 + \gamma_2 = \gamma} m(\gamma_1, \gamma_2) \det_{\lambda+\gamma_1}(A) \det_{\lambda+\gamma_2}(B).$$

Proof. Apply the previous Lemma, expand the products, use the compatibility conditions, and finally apply the previous Lemma again. \(\square\)

Lemma 2.6 (Generalized Laplace extension). Fix a partition $d_1 + \cdots + d_k = d(\gamma)$, where $d_1, \ldots, d_k \in \mathbb{Z}_+$. Then

$$\left( \frac{d(\gamma)}{d_1, \ldots, d_k} \right)^{\det_{\lambda+\gamma}} = \sum_{\gamma_1 + \cdots + \gamma_k = \gamma} m(\gamma_1, \ldots, \gamma_k) \prod_{i=1}^k \det_{\lambda+\gamma_i},$$

where the sum is taken over all decompositions such that $d(\gamma_i) = d_i$.

Proof. By Proposition 2.4

$$\sum_{\gamma_1 + \cdots + \gamma_k = \gamma} m(\gamma_1, \ldots, \gamma_k) \prod_{i=1}^k \det_{\lambda+\gamma_i} (\sum_{\beta \in B} a_\beta X_\beta) =$$

$$= \sum_{\gamma_1 + \cdots + \gamma_k = \gamma} m(\gamma_1, \ldots, \gamma_k) \prod_{i=1}^k \left( \sum_{\beta_1 + \cdots + \beta_i = \gamma_i} m(\beta_1^i, \ldots, \beta_i^d(\gamma_i)) \prod_{j=1}^{\beta_i^d(\gamma_i)} a_{\beta_j} \right).$$

By expanding the first product we obtain:

$$\sum_{\gamma_1 + \cdots + \gamma_k = \gamma} \sum_{\beta_1 + \cdots + \beta_i = \gamma_i} m(\gamma_1, \ldots, \gamma_k) \prod_{i=1}^k \prod_{j=1}^{\beta_i^d(\gamma_i)} a_{\beta_j}.$$ We can now apply Lemma 2.2. We get:

$$\sum_{\gamma_1 + \cdots + \gamma_k = \gamma} \sum_{\beta_1 + \cdots + \beta_i = \gamma_i} m(\beta_1^i, \ldots, \beta_i^d(\gamma_i)) \prod_{j=1}^{\beta_i^d(\gamma_i)} a_{\beta_j}.$$ The first two sums give a sum over all decompositions of $\gamma$ into elements from $B$, each decomposition counted $\left( \frac{d(\gamma)}{d_1, \ldots, d_k} \right)$ times. By Proposition 2.4 this gives the result. \(\square\)

3. The secant and tangent varieties in cumulant coordinates

3.1. Minuscule cumulants. We introduce two changes of coordinates on $A_\lambda$.

First, we let $y_{\lambda+\beta} := x_{\lambda+\beta}$ for $\beta \in B$, and if $d(\gamma) > 1$,

$$y_{\lambda+\gamma} := \sum_{\gamma = \gamma_1 + \gamma_2} (-1)^{d(\gamma_2)} m(\gamma_1, \gamma_2) x_{\lambda+\gamma_1} \det_{\lambda+\gamma_2} (\sum_{\beta \in B} x_{\lambda+\beta} X_\beta).$$

Notice that this is an automorphism of $A_\lambda$ as $x_{\lambda+\gamma}$ appears in $y_{\lambda+\gamma}$ with coefficient 1 corresponding to the decomposition $\gamma = \gamma + 0$, while all the other $x_b$ that appear satisfy $b > \lambda + \gamma$. Thus the automorphism is triangular.

Second, we let $z_{\lambda+\beta} := y_{\lambda+\beta}$ for $\beta \in B$, and for $d(\gamma) > 1$,

$$z_{\lambda+\gamma} = \sum_{\gamma_1 + \cdots + \gamma_k = \gamma} \frac{(-1)^k}{d(\gamma)} m(\gamma_1, \ldots, \gamma_k) \prod_{i=1}^k y_{\lambda+\gamma_i}.$$
Here the sum is taken over decompositions such that \(d(\gamma_i) \geq 2\) for each \(i\). As before we obtain a triangular automorphism.

3.2. The secant in cumulant coordinates. We start with the following auxiliary lemma, cf. [MOZ12].

**Lemma 3.1.** Let \(P_k(t) = (-t)^k(1 - t) + t(1 - t)^k\). Then

\[
P_k(t) \prod_{i=1}^{k}(a_i - b_i) = \sum_{A \subseteq \{1, \ldots, k\}} (-1)^{k-|A|} (t \prod_{i \in A} a_i + (1 - t) \prod_{i \in A} b_i) \prod_{i \in \{1, \ldots, k\} \setminus A} (ta_i + (1 - t)b_i)
\]

**Proof.** We consider the right hand side (RHS) as a polynomial of degree \(k\) in \(a_i, b_i\) with coefficients in \(k[t]\). By pairing sets \(A\) differing only by given \(i_0\) we see that the RHS is zero if \(a_{i_0} = b_{i_0}\) for some index \(i_0\). Thus we must have a factor \(\prod_{i=1}^{k}(a_i - b_i)\) on the LHS, and the missing factor is a polynomial \(P_k(t)\). The proof is thus reduced to finding \(P_k(t)\) for fixed values of \(a_i, b_i\). This can be done by an easy induction - c.f. proof of [MOZ12][Lemma 3.1].

We are now ready to present the parametrization of the secant in coordinates \(y_b\). Recall we have parametrized it by mapping \((t, a, b) \in \mathbb{C} \times \mathfrak{a} \times \mathfrak{n}\) to

\[
(t \det_{\gamma + \lambda}(\sum \alpha X_\beta) + (1 - t)\det_{\gamma + \lambda}(\sum \beta X_\beta))_{\gamma + \lambda \in F} \in \mathbb{A}_\lambda.
\]

**Lemma 3.2.** After the change of coordinates to \(y_b\), the parametrization of the secant is given by \(y_{\lambda + \beta} = ta_\beta + (1 - t)b_\beta\) for \(\beta \in B\), and for \(d(\gamma) > 1\) by:

\[
y_{\lambda + \gamma} = P_{d(\gamma)}(t)\det_{\lambda + \gamma}(\sum_{\beta \in B}(a_\beta - b_\beta)X_\beta).
\]

**Proof.** For \(d(\gamma) > 1\), we compute that \(y_{\lambda + \gamma}\) is given by

\[
\sum_{\gamma = \gamma_1 + \gamma_2} (-1)^{d(\gamma_2)} m(\gamma_1, \gamma_2)(t \det_{\lambda + \gamma_1}(\sum \alpha X_\beta) +
\]

\[
(1 - t)\det_{\lambda + \gamma_2}(\sum \beta X_\beta) \det_{\lambda + \gamma_2}(\sum (ta_\beta + (1 - t)b_\beta)X_\beta).
\]

We expand the determinants using Proposition [2.3]. We get

\[
\sum_{\gamma = \gamma_1 + \gamma_2} (-1)^{d(\gamma_2)} m(\gamma_1, \gamma_2)(\sum_{\beta_j = \gamma_1} m(\beta_1, \ldots, \beta_{d(\gamma_1)})(t \prod_j a_{\beta_j} + (1 - t) \prod_j b_{\beta_j}) \times
\]

\[
\times (\sum_{\beta_j = \gamma_2} m(\beta_1', \ldots, \beta_{d(\gamma_2)}) \prod_i (ta_{\beta_i} + (1 - t)b_{\beta_i})).
\]

Note that the triple sum \(\sum_{\gamma = \gamma_1 + \gamma_2} \sum_{\beta_j = \gamma_1} \sum_{\beta_j' = \gamma_2}\) is just the sum over all decompositions \(\sum_{\beta_i = \gamma} \sum_{A \subseteq \{1, \ldots, d(\gamma)\}} \sum_{\beta_i \in A} \beta_i\). Therefore we obtain:

\[
\sum_{\sum_{\beta_i = \gamma} \sum_{\beta_i \in A \subseteq \{1, \ldots, d(\gamma)\}} (-1)^{d(\gamma) - |A|} m(\sum_{\beta_i} \beta_i, \sum_{\beta_i \in A \setminus \{1, \ldots, k\}} \beta_i) m((\beta_i)_{i \in \{1, \ldots, k\}}) \times
\]

\[
(t \prod_{i \in A} a_{\beta_i} + (1 - t) \prod_{i \in A} b_{\beta_i}) \prod_{i \in \{1, \ldots, k\} \setminus A} (ta_{\beta_i} + (1 - t)b_{\beta_i}).
\]
By applying Lemma 2.2 and Lemma 3.1 we get:

\[ \sum_{\sum_i \beta_i = \gamma} m(\beta_1, \ldots, \beta_{d(\gamma)}) P_{d(\gamma)}(t) \prod_i (a_{\beta_i} - b_{\beta_i}), \]

which finishes the proof by Proposition 2.4. \( \square \)

We now compute the parametrization in the coordinates \( z_b \).

Lemma 3.3. After the change of coordinates to \( z_b \) the parametrization of the secant is given by \( z_{\lambda+\gamma} = ta_{\beta} + (1-t)b_{\beta} \) for \( \beta \in B \), and for \( d(\gamma) > 1 \) by

\[ z_{\lambda+\gamma} = t(1 - t)(1 - 2t)^{d(\gamma)-2} \det_{\lambda+\gamma}(\sum_{\beta \in B} (a_{\beta} - b_{\beta}) X_{\beta}). \]

Proof. For \( d(\gamma) > 1 \) we have

\[ z_{\lambda+\gamma} = \sum_{\gamma_1 + \cdots + \gamma_k = \gamma} \frac{(-1)^k}{d(\gamma)} m(\gamma_1, \ldots, \gamma_k) \prod_{i=1}^k P_{d(\gamma)}(t) \det_{\gamma+\lambda}(\sum_{\beta \in B} (a_{\beta} - b_{\beta}) X_{\beta}), \]

where the sum is taken over such decompositions that \( d(\gamma_i) \geq 2 \). This equals:

\[ \sum_{d_1 + \cdots + d_k = d(\gamma)} \frac{(-1)^k}{d(\gamma)} \prod_{i=1}^k P_{d_i}(t) \sum_{\gamma_1 + \cdots + \gamma_k = \gamma} m(\gamma_1, \ldots, \gamma_k) \prod_{i=1}^k \det_{\gamma_i + \lambda}(\sum_{\beta \in B} (a_{\beta} - b_{\beta}) X_{\beta}), \]

where the second sum is taken over such decompositions that \( d(\gamma_i) = d_i \geq 2 \). By Lemma 2.6 we obtain:

\[ \sum_{d_1 + \cdots + d_k = d(\gamma)} (-1)^k \prod_{i=1}^k P_{d_i}(t) \det_{\lambda+\gamma}(\sum_{\beta \in B} (a_{\beta} - b_{\beta}) X_{\beta}). \]

Thus the statement is reduced to proving:

\[ \sum_{d_1 + \cdots + d_k = d(\gamma)} (-1)^k \prod_{i=1}^k P_{d_i}(t) = t(1 - t)(1 - 2t)^{d(\gamma)-2}, \]

as \( P_1(t) = 0 \). We leave it as an exercise, c.f. [MOZ12]. \( \square \)

As \( \det_{\lambda+\gamma} \) is a polynomial of degree \( d(\gamma) \) we obtain the following result.

Theorem 3.4. The secant variety of the minimal orbit \( Y \) in a minuscule and cominuscule representation can be covered by complements of hyperplane sections isomorphic to a product of an affine space of the same dimension as \( Y \), with the affine cone over the projective variety parameterized by all generalized determinants of degree strictly greater than one.

On such an affine chart, the closure of the minimal orbit is defined by the relations among all the generalized determinants, while the secant is defined by the homogeneous relations among those generalized determinants that are of degree strictly greater than one.
3.3. The tangent in cumulant coordinates. Similar algebraic tricks can be applied to a parametrization of the tangential variety of the minimal orbit in a minuscule and cominuscule representation. However, instead of performing the computations we can rely on the results we have obtained so far.

Lemma 3.5. Let us fix two points on the minimal orbit $e^{n_1} v_\lambda, e^{n_1+en_2} v_\lambda$ for $n_1, n_2 \in \mathbb{n}$ and $\epsilon \in \mathbb{C}$. The secant line in $\mathbb{A}_\lambda$ joining these points is parameterized by:

$$\mathbb{C} \ni t \mapsto te^{n_1} v_\lambda + (1-t)e^{n_1+en_2} v_\lambda \in \mathbb{A}_\lambda.$$ 

After the change of coordinates to $z_\lambda$, the parametrization of this line is given by:

$$z_{\lambda+\beta} = t \det_{\lambda+\beta}(n_1) + (1-t) \det_{\lambda+\beta}(n_1 + en_2),$$

for $\beta \in B$ and for $d(\gamma) > 1$ by:

$$z_{\lambda+\gamma} = t(1-t)(1-2t)^{d(\gamma)-2} \det_{\lambda+\gamma}(-en_2).$$

Proof. This is a special case of the computation in Lemma 3.3.

Proposition 3.6. In the coordinates $z_\beta$, the tangential variety is a product of the affine space defined by the coordinates $z_{\lambda+\beta}$, by the affine variety parameterized for $d(\gamma) > 1$ by $z_{\lambda+\gamma} = c \det_{\lambda+\gamma}(n)$, with $n \in \mathbb{n}$ and $c$ a fixed constant.

Proof. Let $T$ be the Zariski closure of the given parametrization. First we show that the tangential variety contains $T$. By Proposition 3.3 the generalized determinants are homogeneous polynomials. Thus, the secant lines from Lemma 3.3 can be parameterized for $d(\gamma) > 1$ by

$$z_{\lambda+\gamma} = (-\epsilon t)(-\epsilon + \epsilon t)(-\epsilon + 2\epsilon t)^{d(\gamma)-2} \det_{\lambda+\gamma}(n_2).$$

Taking $t = 1/\epsilon$, as $\epsilon \to 0$ we obtain:

$$z_{\lambda+\gamma} = c \det_{\lambda+\gamma}(-2n_2).$$

Notice that the coordinates $z_{\lambda+\beta}$ are arbitrary as $n_1$ can be chosen arbitrary and the generalized determinants of degree one $\det_{\lambda+\beta}(n_1)$ just return a coordinate of $n_1$. As $\epsilon \to 0$ the secant lines approach tangent lines, so $T$ is indeed contained in the tangential variety. Notice that by Theorem 3.4 the secant variety is a cone over $T$, thus $T$ is of codimension one in the secant variety, as is the tangential variety. The proposition follows.

4. Secants of Grassmannians

The most classical minimal orbits of representations that are minuscule and cominuscule are Grassmannians. The equations of the secant of the Grassmannian $G(k, V)$ embedded by the Plücker embedding are not known in general, apart from the cases $k = 2, 3$ [LW09]. Let us start with the case $k = 2$.

4.1. Pfaffian-Plücker and the $\sigma(G(2, n)) \sim G(2, n-2)$ correspondence. Let $V$ be an $n$ dimensional vector space. Consider $G(2, V) \subset \mathbb{P}(\wedge^2 V)$. We may represent elements of $\wedge^2 V$ as skew symmetric matrices. The points of $G(2, V)$ correspond to matrices of rank 2, hence to degree two minors of a generic $2 \times n$ matrix. Locally, $G(2, V)$ can be parameterized by all minors of a generic $2 \times (n-2)$ matrix. The points of the secant $\sigma(G(2, V))$ correspond to matrices of rank at most 4. Moreover, the ideal of the secant variety is generated by $6 \times 6$ subpfaffians of the generic skew-symmetric matrix.
The Main Theorem 3.4 asserts that \( \sigma(G(2, n)) \) is covered by affine open subsets which are products of a \( 2(n-2) \)-dimensional affine space by the affine cone over the projective variety \( Y \) parameterized by \( 2 \times 2 \) minors of a generic \( 2 \times (n-2) \) matrix, which is \( G(2, n-2) \). The unique singular point over the affine cone corresponds exactly to the points in \( G(2, n) \) itself. In particular we see that the singularities of \( \sigma(G(2, n)) \) are exactly the same as those of the affine cone over \( G(2, n-2) \), which have been well-studied.

**Corollary 4.1.** The secant \( \sigma(G(2, n)) \) is covered by affine varieties \( \mathbb{A}^{2(n-2)} \times \mathcal{G}(2, n-2) \), where \( \mathcal{G}(2, n-2) \) is the affine cone over the Grassmannian \( G(2, n-2) \). In particular it has the same singularities as the cone, e.g. rational – cf. [LW09].

Let us further investigate the correspondence. Fix a basis \( e_1, \ldots, e_n \) of \( V \). In order to fix a principal affine open subset of \( \mathbb{P}(\wedge^2 V) \) we have to choose two vectors \( e_{i_1}, e_{i_2} \). The equations of \( G(2, n-2) \) are known as Plücker relations. They are indexed by the choice of four further vectors \( e_{i_3}, e_{i_4}, e_{i_5}, e_{i_6} \). The chosen Plücker relation after the isomorphisms described in Section 3.1 has to induce an equation of \( \sigma(G(2, n)) \). Plücker relations are quadratic, and so is our change of coordinates. So we could expect a degree 4 equation. However, it turns out that we obtain the subpfaffian indexed by \( i_1, \ldots, i_6 \), which has degree three!

**Example 4.2.** Without loss of generality we assume that \( i_1 = 1 \) and \( i_2 = 2 \), that is we dehomogenize with respect to the variable \( x_{12} \). The Plücker relation corresponding to \( i_3 = 3, i_4 = 4, i_5 = 5, i_6 = 6 \) is given by:

\[
\begin{align*}
    z_{34}z_{56} + z_{45}z_{36} - z_{46}z_{35}.
\end{align*}
\]

The isomorphism of affine spaces is defied in this case by:

\[
\begin{align*}
    z_{ij} = x_{ij} & \text{ for } i \leq 2 < j, \text{ and } z_{ij} &= x_{12}x_{ij} - x_{1i}x_{2j} + x_{1j}x_{2i}, \text{ for } 2 < i < j.
\end{align*}
\]

After the substitution the Plücker relation equals the Pfaffian of the matrix:

\[
\begin{pmatrix}
    0 & x_{12} & x_{13} & x_{14} & x_{15} & x_{16} \\
-x_{12} & 0 & x_{23} & x_{24} & x_{25} & x_{26} \\
-x_{13} & -x_{23} & 0 & x_{34} & x_{35} & x_{36} \\
-x_{14} & -x_{24} & -x_{34} & 0 & x_{45} & x_{46} \\
-x_{15} & -x_{25} & -x_{35} & -x_{45} & 0 & x_{56} \\
-x_{16} & -x_{26} & -x_{36} & -x_{46} & -x_{56} & 0
\end{pmatrix}.
\]

### 4.2. General case.

Motivated by Main Theorem 3.4 we make the following definition:

**Definition 4.3** (\( \tilde{M}_{a,b}, M_{a,b} \)). For two natural numbers \( a, b \in \mathbb{Z} \) we define the embedded projective variety \( \tilde{M}_{a,b} \) as the Zariski closure of the map that to a generic \( a \times b \) matrix associates all its minors of degree at least 2. In particular, \( \tilde{M}_{2,b} = G(2, b) \). Let \( M_{a,b} \) be the affine cone over \( \tilde{M}_{a,b} \).

As another corollary of 3.4 we obtain:

**Corollary 4.4.** The secant variety \( \sigma(G(k, n)) \) is covered by principal open affine sets isomorphic to \( \mathbb{A}^{k \times (n-k)} \times M_{k,n-k} \).

Thus the equations of \( \sigma(G(k, n)) \), after the affine isomorphism, give homogeneous relations among minors and vice versa. The study of relations among minors is a very classical problem. In general the generators of these relations are unknown, apart from the case of maximal minors, when we have Plücker relations. Still, it is very easy to produce some
quadratic relations by Laplace expansion. Moreover, the conjectural generators in case of $2 \times 2$ minors were provided in \cite{BCV13}.

5. The secant and representation theory

In this section we consider the equations of secant varieties of flag manifolds from the perspective of representation theory. The main case we have in mind is that of Grassmannians.

Let $\lambda$ be a Young diagram with $k$ rows. Let $Y_\lambda$ be the unique closed $GL(V)$-orbit in $\mathbb{P}(S_\lambda V)$, which is the orbit of highest weight vectors.

5.1. Equations of the secant variety. We start by recalling a method for describing the equations of secant varieties due to Landsberg and Manivel \cite{LM04}.

A polynomial $P$ belongs to the ideal of the $(s-1)$-st secant variety if and only if for any points $Q_1, \ldots, Q_s$ in the affine cone over $Y_\lambda$, which we call simple vectors, and any complex numbers $a_1, \ldots, a_s$ we have $P(a_1Q_1 + \cdots + a_sQ_s) = 0$. Suppose that $P$ is homogeneous of degree $d$. Recall that to any homogeneous polynomial $P$ of degree $d$ one can associate a $d$-linear form $\tilde{P}$ called the polarization of $P$, so that $\tilde{P}(v, \ldots, v) = P(v)$. It can be defined as:

$$\tilde{P}(v_1, \ldots, v_d) = \frac{1}{d!} \frac{\partial}{\partial \lambda_1} \cdots \frac{\partial}{\partial \lambda_d} P(\lambda_1v_1 + \cdots + \lambda_dv_d)_{\lambda=0}.$$ 

If we consider $P(a_1Q_1 + \cdots + a_sQ_s)$ as a polynomial in the $a_i$’s, the coefficient of the monomial $\prod a_i^{\alpha_i}$, up to some constant, is equal to $\tilde{P}(Q_1, Q_1, \ldots, Q_s)$, where each $Q_i$ appears $\alpha_i$ times. All these polynomials must therefore vanish.

The vanishing of a polarization on all $d$-tuples of simple vectors implies its vanishing on the whole space (since $Y_\lambda$ is linearly non degenerate), so this immediately implies:

**Corollary 5.1.** There are no non zero polynomials of degree $d$ vanishing on the $(s-1)$-st secant variety for $d \leq s$. \hfill \Box

**Definition 5.2** ($l \cdot \lambda$). Let $l \cdot \lambda$ be the Young diagram, obtained by multiplying each row of $\lambda$ by $l$. The corresponding representation $S_{l \cdot \lambda}V$ is spanned by the (cone over the) $l$-th Veronese embedding of $Y_\lambda$.

Let us consider a decomposition $\sum_{i=1}^s \alpha_i = d$. To this decomposition we associate the representation $M$ defined by

$$M := S_{\alpha_1}V \otimes \cdots \otimes S_{\alpha_s}V.$$ 

The vector space $M$ is spanned by simple tensors of the form $v_{\alpha_1}(Q_1) \otimes \cdots \otimes v_{\alpha_s}(Q_s)$, where $v_i$ is the $i$-th Veronese embedding and the $Q_i$ are simple vectors in $S_\lambda V$. We may define a linear form on $S^d(S_\lambda V^*) \otimes M$, that to a polynomial $P$ of degree $d$ and a tensor $v_{\alpha_1}(Q_1) \otimes \cdots \otimes v_{\alpha_s}(Q_s) \in M$ associates $\tilde{P}(Q_1, Q_1, \ldots, Q_s)$, where each $Q_i$ appears $\alpha_i$ times. After dualizing, we get a map

$$f_\alpha : S^d(S_\lambda V^*) \to M^*.$$ 

The observations above can be stated as follows.

**Proposition 5.3.** Let $I_d$ be the $d$-th graded part of the ideal of $\sigma_{s-1}(Y_\lambda)$. Then

$$I_d = \cap_\alpha \ker f_\alpha,$$

where the intersection is over all possible decompositions $\sum_{i=1}^s \alpha_i = d$. \hfill \Box
The kernels of the maps $f_\alpha$ are hard to describe in general. However, we can restrict each $f_\alpha$ to an isotypic component $R_\mu$ corresponding to a Young diagram $\mu$ to obtain a bound on its multiplicity in the ideal.

**Corollary 5.4.** Let us fix a component $\mu$ of weight $dk$. For a given decomposition $\alpha$ given by $\sum_{i=1}^s \alpha_i = d$ let $m_\alpha$ be the multiplicity of the component given by $\mu$ inside $\bigotimes_{i=1}^s S_{\alpha_i}V^*$. Let $m = \sum_\alpha m_\alpha$, where the sum is over all possible decompositions $\alpha$ of $d$.

Then the multiplicity of $S_\mu V^*$ in the degree $d$ part of the ideal of $\sigma_{s-1}(Y_\lambda)$ is at least its multiplicity inside $S^d(S_\lambda V^*)$ minus $m$.

Let us give a first application. Recall that $\lambda$ has $k$ rows.

**Corollary 5.5.** All isotypic components of $S^d(S_\lambda V^*)$ that correspond to Young diagrams with either

- the $r \downarrow \downarrow s$ column of length strictly less than $k$,
- more than $ks$ rows,

are contained in the ideal of $\sigma_{s-1}(Y_\lambda)$.

**Proof.** Under each of these two hypotheses, it follows from the Littlewood-Richardson rule that $m_\alpha = 0$ for any decomposition $\alpha$ of $d$. \hfill $\square$

5.2. **Stabilization.** To a vector space $V$ and a Young diagram $\lambda$ with $k$ rows we have associated a projective variety $Y_\lambda$. In this subsection the vector space $V$ will not be fixed, thus we will consider the variety $Y_\lambda V$. As the dimension of $V$ changes, also the properties of the secant variety $\sigma_s(Y_\lambda V)$ may change. However, certain properties will stabilize, as the dimension of $V$ grows.

**Proposition 5.6.** The multiplicities of isotypic components of the graded ring of $\sigma_s(Y_\lambda V)$, considered as $GL(V)$-representations, are independent of $V$ as long as $\dim V \geq (s + 1)k$.

**Proof.** This follows from the methods explained in Subsection 5.1. Indeed, in the domains of the maps $f_\alpha$, there only appear representations given by Young diagrams with at most $(s + 1)k$ rows. \hfill $\square$

Among interesting properties of $\sigma_s(Y_\lambda)$ such as being (arithmetically) Gorenstein, (arithmetically) Cohen-Macaulay, (projectively) normal etc., we do not know which ones stabilize and under which bounds on the dimension. As far as equations are concerned we have the following result.

**Proposition 5.7.** Suppose that $\sigma_s(Y_{\lambda,V})$ is defined ideal-theoretically (resp. set-theoretically, resp. scheme-theoretically) by equations of degree at most $d$ for $\dim V = (s + 2)k$. Then the same is true for $\sigma_s(Y_{\lambda,V'})$ for any $V'$ with $\dim V' \geq \dim V$.

**Proof.** We prove only the ideal-theoretic version, the other versions being analogous. Let $I_V$ and $I_{V'}$ be the ideal of respectively $\sigma_s(Y_{\lambda,V})$ and $\sigma_s(Y_{\lambda,V'})$, where $\dim V' \geq \dim V$. We consider $V$ as a subspace of $V'$ and we choose a splitting $V' = V \oplus W$. Then there is an induced projection map from $S_\lambda V'$ to $S_\lambda V$, and the image $Y_{\lambda,V'}$ is exactly $Y_{\lambda,V}$. Therefore the same is true for the secants and this implies that $I_V$ is contained in $I_{V'}$.

We choose a maximal torus in $GL(V')$ given by the product of a maximal torus in $GL(V)$ times a maximal torus in $GL(W)$. Moreover we order a basis in which this torus is made of diagonal matrices by taking vectors from $V$ before vectors from $W$. This implies that a highest weight vector in any $S_\mu V'$ belongs to $S_\mu V$ if $\mu$ has less than $d$ rows.
We will use this observation to show that all highest weight vectors in \( I_{\nu'} \) are generated in degree at most \( d \). As the ideal is \( GL(V') \)-equivariant the proposition will follow.

**Step 1.** We first consider highest weight vectors corresponding to Young diagrams with at most \( d = k(s + 2) \) rows. As we have just seen, a polynomial \( P \in I_{\nu'} \) that is such a highest weight vector belongs to \( S^*(S_\lambda V) \). Therefore \( P \) belongs to \( I_{\nu} \), thus it is generated in degree at most \( d \) in \( I_{\nu} \) over the ring \( S^*(S_\lambda V)^* \), hence also in \( I_{\nu'} \) over the ring \( S^*(S_\lambda V')^* \) since \( I_{\nu} \subset I_{\nu'} \).

**Step 2.** Now we consider highest weight vectors corresponding to Young diagrams with more than \( k(s + 2) \) rows. Fix a polynomial \( P \in I_{\nu'} \), of degree \( d' \), that is such a highest weight vector. The proof is inductive on \( d' \), which we may suppose to be bigger than \( d \). Consider the canonical map:

\[
mult : S^{d'-1}(S_\lambda V^*) \otimes S_\lambda V^* \to S^{d'}(S_\lambda V^*),
\]

that corresponds to multiplication of polynomials. We may decompose the representation \( S^{d'-1}(S_\lambda V^*) \) into a direct sum of isotypic components. Note that by the Littlewood-Richardson rule, only isotypic components with more than \( k(s + 1) \) rows can be mapped by \( \text{mult} \) to the isotypic component represented by \( \mu \). As \( \text{mult} \) is surjective we see that:

\[
P = \sum l_i Q_i,
\]

where the \( l_i \) are linear forms and the \( Q_i \) belong to isotypic components represented by Young diagrams with more than \( k(s + 1) \) rows. By Corollary 5.5 we know that \( Q_i \) belongs to \( I_{\nu'} \). By the inductive assumption all \( Q_i \) are generated in degree at most \( d \), which finishes the proof.

5.3. **Cubic equations of the secant.** In this subsection we will provide the description of cubics vanishing on the secant of a Grassmannian \( G(k, V) \) as a subrepresentation of \( S^3(\bigwedge^k V)^* \). The space of such cubics will be denoted by \( I_3 \). We will give explicit formulas for the multiplicities of each irreducible component. When these multiplicities are smaller than the corresponding multiplicities in \( S^3(\bigwedge^k V)^* \) we will explicitly provide linear forms cutting out the highest weight space in \( I_3 \). A partial result was given in [LW09, Proposition 1.6, Section 3].

Let us start with general remarks. First note that Lemma 6.3 applies to the ideal of the secant as follows.

**Proposition 5.8** (Reduction for secants). Let \( \lambda \) be a Young diagram with \( d \) columns, and denote by \( \lambda' \) the diagram obtained by removing the first row. Then the multiplicity of the component corresponding to \( \lambda \) inside \( I_d(\sigma_s(G(k, n))) \) is equal to the multiplicity of the component corresponding to \( \lambda' \) inside \( I_d(\sigma_s(G(k - 1, n - 1))) \).

**Proof.** Let \( P \in S^d(\bigwedge^k \mathbb{C}^n)^* \) be any polynomial in the highest weight space corresponding to \( \lambda \). Denoting by \( e_1, \ldots, e_n \) the canonical basis of \( \mathbb{C}^n \), let \( Q \) be the set of variables that correspond to wedge products of basis elements that contain \( e_1 \). The polynomial \( P \) is a polynomial in these variables only. Let \( i \) be an application that to a wedge product of basis vectors containing \( e_1 \) associates the same wedge product without \( e_1 \) and with all indices decreased by one. We can identify the variables from \( Q \) with variables of \( \bigwedge^{k-1} \mathbb{C}^{n-1} \). By this identification points of the Grassmannian \( G(k, n) \) correspond to points of \( G(k - 1, n - 1) \). Moreover \( P \) belongs to the ideal of \( \sigma_s G(k, n) \) if and only if \( i(P) \) belongs to the ideal of \( \sigma_s G(k - 1, n - 1) \).
Let us focus on the case where \( s = 2 \) and \( d = 3 \). Using Proposition 5.8 it is enough to obtain the multiplicities corresponding to Young diagrams with at most two columns. For this we apply Proposition 5.3. There are only two decompositions of 3 to consider: \( 3 = 1 + 2 \) and \( 3 = 0 + 3 \). The latter provides only one component, corresponding to the Young diagram with three columns of length \( k \). The decomposition \( 3 = 1 + 2 \) gives many components, but only one of them has two columns. This component has got the first column of length 2 and the second one of length \( k \). It appears with multiplicity one in the tensor product.

Using Lemma 5.4, we get the following Proposition.

**Proposition 5.9.** All representations corresponding to Young diagrams with two columns different from \((2k, k)\) appear with the same multiplicity in \( S^3(\bigwedge^k V^*) \) as in \( I_3 \). For the component \((2k, k)\) the multiplicity may drop at most by 1.

We will now prove that in fact the latter multiplicity always drops by one. We will do this by providing a linear form on the highest weight space that will cut out the ideal. More precisely we will give an example of a polynomial in the highest weight space of \((2k, k)\) that does not vanish on the point \( Q := e_1 \wedge \cdots \wedge e_k + e_{k+1} \wedge \cdots \wedge e_{2k} \). Our construction is motivated by a general method of defining highest weight vectors in plethysms described in [MM12].

**Definition 5.10** \((x_{a_1 \ldots a_k})\). By \( x_{a_1 \ldots a_k} \) we denote a linear form, or equivalently a variable, corresponding to \( e_{a_1}^* \wedge \cdots \wedge e_{a_k}^* \). If we permute the \( a_i \)'s then the variable changes sign according to the sign of the permutation.

For \( k \) even we consider the polynomial

\[
P = \sum_{\sigma \in S_{2k}} \text{sgn}(\sigma) x_{\sigma(1) \ldots \sigma(k)} x_{\sigma(k+1) \ldots \sigma(2k)} x_{1 \ldots k}.
\]

This is a highest weight vector for the weight \((2k, k)\). Moreover it contains only one monomial that is nonzero on \( Q \), namely \( x_{1 \ldots k}^2 x_{k+1 \ldots 2k} \). In particular \( P(Q) \neq 0 \).

For \( k \) odd we consider the polynomial

\[
P = \sum_{\sigma \in S_{2k}, \delta \in S_k} \text{sgn}(\sigma) \text{sgn}(\delta) x_{\sigma(1) \ldots \sigma(k)} x_{\sigma(k+1) \ldots \sigma(2k-1), \delta(1)} x_{\sigma(2k), \delta(2) \ldots \delta(k)} x_{\sigma(k+1) \ldots \sigma(2k), \delta(2) \ldots \delta(k)} x_{1 \ldots k}.
\]

We want to show that \( P(Q) \neq 0 \). First let us consider one monomial

\[
x_{\sigma(1) \ldots \sigma(k)} x_{\sigma(k+1) \ldots \sigma(2k-1), \delta(1)} x_{\sigma(2k), \delta(2) \ldots \delta(k)}
\]

appearing in the sum defining \( P \). If the monomial is nonzero on \( Q \) all the variables, up to permutation of indices must be either \( x_{1 \ldots k} \) or \( x_{k+1 \ldots 2k} \). As \( x_{\sigma(k+1) \ldots \sigma(2k-1), \delta(1)} \) and \( x_{\sigma(2k), \delta(2) \ldots \delta(k)} \) contain indices less or equal to \( k \) they must be, up to sign, \( x_{1 \ldots k} \). Hence \( x_{\sigma(1) \ldots \sigma(k)} \) must be \( x_{k+1 \ldots 2k} \). We see that \( P(Q) \neq 0 \) is equivalent to

\[
\sum_{\sigma \in S_k, \delta \in S_k, \sigma(\delta(1)) = \delta(1)} \text{sgn}(\sigma) \text{sgn}(\delta) x_{\sigma(1) \ldots \sigma(k-1), \delta(1)} x_{\sigma(k), \delta(2) \ldots \delta(k)} x_{k+1, \ldots, 2k} \neq 0.
\]

Notice that since \( k \) is odd all these monomials have coefficients of the same sign, hence the sum is nonzero. This concludes the proof of the main theorem of this subsection:

**Theorem 5.11.** Let \((a, b, c)\) denote the isotypic component corresponding to the Young diagram with three columns of lengths respectively \(a, b, c\). The multiplicity of the component \((a, b, c)\) in the ideal \( I_3(\sigma(G(k, n))) \) is zero for \( n < a \). Otherwise it is equal to

1. the multiplicity of \((a - c, b - c, 0)\) in \( S^3(\bigwedge^{k-c}) \) if \( a - c \neq 2(b - c) \),
(2) the multiplicity of $(2(b-c), b-c, 0)$ in $S^3(\bigwedge^{k-c})$ minus one if $a - c = 2(b - c)$ (and $b = k$). In this case the polynomial in the highest weight space is in $I_3$ if and only if it does not contain the monomial $x_1^2x_{k+1}...x_{2k}$.

In other words, by restricting cubics to the secant variety $\sigma(G(k, n))$ we get

$$\mathbb{C}[\sigma(G(k, n))]_3 = \bigoplus_{c=0}^{k} S_{\alpha(k,c)} V^*,$$

where the Young diagram $\alpha(k, c)$ has columns of lengths $(2k - c, k, c)$.

5.4. The complexity of the secant. Recall that the complexity of a $G$-variety $X$, where $G$ is a reductive group, is defined as the codimension of the generic $B$-orbit, where $B$ is a Borel subgroup of $G$. By [LW07] the complexity of the tangential variety is zero (otherwise said the tangential variety is spherical). This immediately implies that the secant variety has complexity at most one. Let us prove that there is equality.

**Proposition 5.12.** The complexity of the secant variety of a Grassmannian is one.

**Proof.** For simplicity we just treat the case of a Grassmannian $G(k, 2k), k \geq 3$, the general case being similar. A generic point of the secant is of the form $p = [u_1 \wedge \cdots \wedge u_k + v_1 \wedge \cdots \wedge v_k]$, where $u_1, \ldots, u_k$ and $v_1, \ldots, v_k$ are basis of two transverse subspaces $U$ and $V$. Suppose that $M \in GL(2k)$ belongs to the connected component of the stabilizer of $p$, then we have $M = X + Y$ where $X \in \text{End}(U)$ and $Y \in \text{End}(V)$ are such that $\det(X) = \det(Y)$.

Consider a Borel subgroup $B$ of $GL(2k)$ defined as the stabilizer of a generic complete flag of subspaces $L_1 \subset \cdots \subset L_{2k-1}$. Each $L_i$ is generated by vectors $\ell_1, \ldots, \ell_i$ and we may suppose that for $i \leq k$, $\ell_i = u_i + v_i$. For $i > k$, we may suppose that $\ell_i = a_{i-k}$ belongs to $U$ or $\ell_i = b_{i-k}$ belongs to $V$.

If $M \in B$ belongs to the connected component of the stabilizer of $p$, we decompose $M = X + Y$ as above. Then $X$ (respectively $Y$) must preserve the flag of subspaces of $U$ (respectively $V$) defined by the vectors $u_1, \ldots, u_k$ (respectively $v_1, \ldots, v_k$), and the matrices of $X$ and $Y$ in these basis must be the same. Moreover, $M$ also has to preserve the flag defined by the vectors $a_1, \ldots, a_k$. But the intersection in $GL(k)$ of two Borel subgroups stabilizing two complete flags in general position is just a maximal torus. Therefore the connected component of the stabilizer of $p$ in $B$ is isomorphic to a maximal torus of $GL(k)$, in particular its dimension is $k$.

We conclude that the $B$-orbit of $p$ has dimension $\dim(B) - k = 2k^2$ which is one less than the dimension of the secant variety. \qed

A consequence of this observation is that the multiplicities in the coordinate ring of the secant variety can only grow linearly. These multiplicities are bounded by those of the coordinate ring of the $GL(2k)$ orbit $\mathcal{O}$ of $p$, which is open in the secant. We have seen in the previous proof that the connected component of the stabilizer is the subgroup $S(GL(k) \times GL(k))$ of $GL(k) \times GL(k)$ defined as the set of pairs of matrices with the same determinant. More precisely

$$\mathcal{O} \simeq GL(2k)/S(GL(k) \times GL(k)) \rtimes \mathbb{Z}_2.$$
Proposition 5.13. The coordinate ring of the open orbit \( O \) in the secant variety of the Grassmannian \( G(k,W) \), where \( W \) has dimension \( 2k \), is
\[
\mathbb{C}[O] = \bigoplus_{\alpha \in D_k} \left[ \frac{\alpha_k - \alpha_{k+1} + 1}{2} \right] S_{\alpha}W^*,
\]
where \( D_k \) is the set of non increasing sequences \( \alpha = (\alpha_1, \ldots, \alpha_{2k}) \) of relative integers, such that \( \alpha_i + \alpha_{2k+1-i} \) is independent of \( i \). Here, \( \alpha_i \) is the length of the \( i \)-th row of the corresponding Young diagram.

Proof. With the same notation as before, the \( GL(2k) \)-orbit of the point \( u_1 \wedge \cdots \wedge u_k + v_1 \wedge \cdots v_k \) is open in the cone over \( O \). Its stabilizer is \( L = (SL(k) \times SL(k)) \rtimes \mathbb{Z}_2 \), with connected component \( L^0 = SL(k) \times SL(k) \). By the Peter-Weyl theorem we have
\[
\mathbb{C}[O] = \mathbb{C}[G]^L = \bigoplus_{\alpha} \dim(S_{\alpha}W)^L S_{\alpha}W^*,
\]
where the sum is over all the non increasing sequences \( \alpha = (\alpha_1, \ldots, \alpha_{2k}) \) of relative integers. In order to determine the dimension of the space \( (S_{\alpha}W)^L \) of \( L \)-invariants we first consider the \( L^0 \)-invariants. Let us write \( \alpha_i = \lambda_i + \ell \), where \( \lambda \) is a partition with \( 2k \)-th part equal to zero, and \( \ell \in \mathbb{Z} \). In the decomposition formula
\[
S_{\alpha}W = S_{\lambda}W \otimes (\det W)^\ell = \bigoplus_{\mu,\nu} c^\lambda_{\mu,\nu} S_{\mu}U \otimes S_{\nu}V \otimes (\det U)^\ell \otimes (\det V)^\ell,
\]
where the \( c^\lambda_{\mu,\nu} \) are the Littlewood-Richardson coefficients, we see that in order to get \( L^0 \)-invariants we need to take \( \mu = (m^k) \) and \( \nu = (n^k) \) for some integers \( m \) and \( n \) (where by \( (m^k) \) we mean the partition with \( k \) parts equal to \( m \)). Then \( S_{m}U \otimes S_{n}V = (\det U)^m \otimes (\det V)^n \), and we will get a one-dimensional space of \( L^0 \)-invariants.

The Littlewood-Richardson rule shows that for \( c^\lambda_{\mu,\nu} \) to be non zero, the partition \( \lambda \) must be of form \( (m + \theta_1, \ldots, m + \theta_k, n - \theta_k, \ldots, n - \theta_1) \). In particular, since \( \lambda_{2k} = 0, \theta_1 = n \). Moreover \( \lambda_i + \lambda_{2k+1-i} = m + n \) is independent of \( i \). If these conditions are fulfilled, then \( c^\lambda_{\mu,\nu} = 1 \). Note that \( \lambda \) being given, there are several possibilities for \( m = n \), subject to the constraints that \( m + n = \lambda_1, m \geq \lambda_{k+1} \) and \( n \geq 0 \). This means that \( \lambda_{k+1} \leq m \leq \lambda_1 \), and \( 0 \leq n \leq \lambda_k \).

Now we can deduce the \( L \)-invariants. Indeed the \( \mathbb{Z}_2 \) factors in \( L \) switches \( U \) and \( V \), hence \( m \) and \( n \). In particular \( m \) and \( n \) will only contribute to the \( L \)-invariants in the range \( \lambda_{k+1} \leq m, n \leq \lambda_k \), and by symmetry \( (m,n) \) and \( (m',n') = (n,m) \) contribute to a single \( L \)-invariant. This implies the statement. \( \square \)

Remark 5.14. Let us note that the formula for the multiplicities of the isotypic components in \( \mathbb{C}[O] \) from Proposition 5.13 exactly coincides with the upper bounds for the multiplicities in the algebra of the secant variety obtained in Corollary 5.4. Indeed, for those isotypic components each \( m_{\alpha} \) in the Corollary equals one.

6. Appendix - Plethysm

We are investigating the space of polynomials vanishing on the secant of a Grassmannian \( G(k,V) \). Thus the representation \( S^d(\bigwedge^k V)^* \) is of great importance for us. Its decomposition is not known in general. However, it is know for \( d \leq 3 \) [CGR]. For the sake of completeness, and as the results we found contained some misprints we present an easy, combinatorial proof.
We will be using the following duality result.

**Fact 6.1** ([CT92], [Man98]).

\[ S^\mu(S^{2l}V) = S^\mu(\bigwedge^l V) \uparrow, \quad S^\mu(S^{2l+1}V) = S^\mu(\bigwedge^{2l+1} V) \uparrow, \]

where \( \uparrow \) means that each irreducible component corresponding to a Young diagram \( \nu \) is replaced with the component corresponding to the transpose of \( \nu \), denoted \( \nu^\uparrow \).

**Theorem 6.2.** The multiplicity in \( S^3(\bigwedge^k) \) of the isotypic component corresponding to the Young diagram with columns \((a, b, c)\), where \(a + b + c = 3k\), equals:

1. for \( \min(b - c, a - b) \) is even:
   - if \( \max(b - c, a - b) \) is even then \( \uparrow \frac{\min(b - c + 1, a - b + 1)}{6} \),
   - if \( \max(b - c, a - b) \) is odd then \( \downarrow \frac{\min(b - c + 1, a - b + 1)}{6} \),
2. for \( \min(b - c, a - b) \) is odd
   - if \( \min(b - c, a - b) = 0 \mod 3 \) then \( \uparrow \frac{\min(b - c + 1, a - b + 1)}{6} \),
   - if \( \min(b - c, a - b) = 1 \mod 3 \) then \( \downarrow \frac{\min(b - c + 1, a - b + 1)}{6} \),
   - if \( \min(b - c, a - b) = 2 \mod 3 \) then \( \downarrow \frac{\min(b - c + 1, a - b + 1)}{6} \). \( \square \)

The following Lemma 6.3 and Corollary 6.4 are classical. A variation of them can be found for example in [CT92] 5.8, 5.9. However, the proofs that we know usually take advantage of properties of Schur polynomials. We propose a very simple, direct approach, that not only provides equality of multiplicities of isotypic components, but also explicitly gives an isomorphism.

**Lemma 6.3** (Reduction Lemma). Let \( \mu \) be any Young diagram of weight \( n \). Let \( \lambda \) be a Young diagram with \( n \) columns and weight \( nk \). Let \( \lambda' \) be \( \lambda \) with the first row removed. The multiplicity of the component corresponding to \( \lambda \) in \( S^\mu(\bigwedge^k W) \) equals the multiplicity of the component corresponding to \( \lambda' \) in \( S^\mu(\bigwedge^{k-1} W) \).

**Proof.** Consider the inclusion \( S^\mu(\bigwedge^k V) \subset (\bigwedge^k V)^{\otimes n} \) with a basis given by tensor products of wedge product of basis elements of \( V \). Each vector in the highest weight space corresponding to \( \mu \) must contain exactly one \( e_i \) in each tensor. We get an isomorphism of highest weight spaces by removing \( e_1 \) and decreasing by one the indices of other basis vectors. \( \square \)

Due to the dualities we get the following corollary.

**Corollary 6.4.** Let \( \mu \) be any Young diagram of weight \( n \). Let \( \lambda \) be a Young diagram with \( n \) rows and weight \( nk \). Let \( \lambda' \) be equal to \( \lambda \) with the first column removed. The multiplicity of the component corresponding to \( \lambda \) in \( S^\mu(S^k W) \) equals the multiplicity of the component corresponding to \( \lambda' \) in \( S^\mu(S^{k-1} W) \).

Let us give some applications of these easy observations. First we prove the classical decompositions, first obtained by Thrall [Thr], [CGR] 4.1-4.6:

**Proposition 6.5.** One has \( Gl(W) \)-modules decompositions

\[ S^2(S^n W) = \bigoplus S_\lambda W, \quad \bigwedge^2(S^n W) = \bigoplus S_\delta W, \]

where the first sum runs over representations corresponding to \( \lambda \) of weight \( 2n \) with two rows of even length and the second sum runs over representations corresponding to \( \delta \) of weight \( 2n \) with two rows of odd length.
Proof. Consider the multiplicity inside $S^2(S^nW)$ of a component with rows $\lambda_1, \lambda_2$, where $\lambda_1 + \lambda_2 = 2n$. From Lemma 6.4 we know that this multiplicity is equal to the multiplicity of the component with one row of length $\lambda_1 - \lambda_2$ inside $\wedge^2(S^{n-\lambda_2}W)$ for $\lambda_2$ odd, and inside $S^2(S^{n-\lambda_2}W)$ for $\lambda_2$ even. Hence it is one for $\lambda_2$ even and zero for $\lambda_2$ odd. A similar argument leads to the second equality.

We proceed to the proof of Theorem 6.2. Due to the dualities 6.1 we may consider only $S^\mu(S^kW)$ for $S^\mu$ a third symmetric or skew-symmetric power. Let us introduce some notation for symmetric polynomials.

**Definition 6.6** $(h_k(x^a), \psi_\alpha(h_k))$. Consider $d$ variables $x_1, \ldots, x_d$. For $\alpha \in \mathbb{N}$ let $h_k(x^a)$ be the complete symmetric polynomial of degree $k$ in the variables $x_1^a, \ldots, x_d^a$. We also define for a multi-index $\alpha$ of length $j$:

$$\psi_\alpha(h_k) := \prod_{i=1}^{j} h_k(x^{\alpha_i}).$$

The character of the representation $S^\mu(S^kW)$ equals $\sum \pm \frac{d!}{\alpha!} \psi_\alpha(h_k)$, where the sum is taken over all partitions $\alpha$ of $d$ and $z_\alpha$ is the number of permutations of combinatorial type $\alpha$ in the group $S_d$. Our aim is to decompose $\psi_\alpha(h_k)$ into a sum of Schur polynomials. To do this we multiply $\psi_\alpha(h_k)$ by the discriminant $\prod_{i<j}(x_i - x_j)$. Assume that there are $d-1$ variables.

The coefficient of $s_\lambda$ inside $\psi_\alpha(h_k)$ equals the coefficient of the monomial $x_1^{\lambda_1+d-2} \cdots x_d^{\lambda_{d-1}}$ in $\psi_\alpha(h_k) \prod_{i<j}(x_i - x_j)$ [FH91, Appendix], [Mac98].

Let $d = 3$. By Lemma 6.4 we can assume that $\lambda$ has two rows $\lambda_1, \lambda_2$ with $\lambda_1 + \lambda_2 = 3k$. There are 3 partitions of the number 3 to consider.

1. $3 = 1 + 1 + 1$. Here we need to compute the contribution of $h_3(x^3)$. This follows from Pieri’s rule. This contribution is equal to $\lambda_2 + 1$ for $\lambda_2 \leq k$, and $\lambda_1 - \lambda_2 + 1$ for $\lambda_2 \geq k$.

2. $3 = 2 + 1$. Note that the coefficient of a monomial $x_1^{3k-a}x_2^a$ in $h_k(x^3)h_k(x)$ for $a \leq 2k$ equals the number of even integers less or equal to $a$ and greater or equal to $\max(0, a-k)$. We can easily deduce the coefficient of $x_1^{\lambda_1+1}x_2^{\lambda_2}$ in $(x_1 - x_2)h_k(x)h_k(x)$. When $\lambda_2 \leq k$, we get 0 for $\lambda_2$ odd, and 1 for $\lambda_2$ even. When $\lambda_2 \geq k$, we get 0 for $k$ odd, while for $k$ even we get 1 if $\lambda_2$ is even, and $-1$ if $\lambda_2$ is odd.

3. $3 = 3$. The coefficient of $x_1^{3k-a}x_2^a$ in $h_k(x^3)$ is equal to 1 if $a$ is divisible by 3 and 0 otherwise. Thus the coefficient of $x_1^{\lambda_1+1}x_2^{\lambda_2}$ in $(x_1 - x_2)S^k(x^3)$ is equal to 1 if $\lambda_2 = 0 \pmod{3}$, $-1$ if $\lambda_2 = 1 \pmod{3}$, 0 if $\lambda_2 = 2 \pmod{3}$.

Finally, recall that the contribution form 1) is taken with coefficient $\frac{1}{6}$, from 2) with $\frac{1}{2}$ and from 3) with $\frac{1}{3}$. This finishes the proof.
