Converse Barrier Functions via Lyapunov Functions

Jun Liu, Senior Member, IEEE

Abstract—We prove a robust converse barrier function theorem via the converse Lyapunov theory. While the use of a Lyapunov function as a barrier function is straightforward, the existence of a converse Lyapunov function as a barrier function for a given safety set is not. We establish this link by a robustness argument. We show that the closure of the forward reachable set of a robustly safe set must be robustly asymptotically stable under mild technical assumptions. As a result, all robustly safe dynamical systems must admit a robust barrier function in the form of a Lyapunov function for set stability. We present the results in both continuous-time and discrete-time settings and remark on connections with various barrier function conditions.

Index Terms—Safety verification and control; barrier functions; stability; Lyapunov functions; robustness.

I. INTRODUCTION

The use of barrier functions to ensure set invariance and safety in control of dynamical systems has gained popularity in recent years in safety-critical control applications [11]–[12]. The readers are referred to [9] for a nice introduction on the background of barrier functions.

From the earlier work [11, 2] to recent results [13, 14], converse theorems for barrier functions played an important role in understanding how safety properties can indeed be characterized by barrier functions. The more stringent conditions in [11, 2] for the existence of converse barrier functions are relaxed in [13] to a class of structurally table dynamical systems (more precisely, Morse-Smale vector fields) and in [14] to a robust safety requirement.

In this paper, inspired by the recent work [14] and the connections made in [10] (see also [9]) between a barrier function and a Lyapunov function, we prove that, for all robustly safe dynamical functions, barrier functions can be constructed from Lyapunov functions. The use of Lyapunov functions to ensure set invariance is standard [15] (see also [1]). The authors of [9, 10] also highlighted that if the barrier function conditions are satisfied in a neighborhood of the safety set, then the barrier function can indeed be regarded as a Lyapunov function. What is missing, however, are conditions under which such barrier functions exist assuming safety of the system. We establish this link by proving that the closure of the robust reachable set of a robustly safe set must be robustly asymptotically stable under mild technical assumptions (Theorem 17). The results of this paper could help provide a potentially more unified view of the Lyapunov function and barrier function theories, because how to simultaneously satisfy Lyapunov and barrier function conditions are important in practice and but technically challenging [9, 12].

This work was supported in part by the Natural Sciences and Engineering Research Council of Canada, the Canada Research Chairs program, and the Government of Ontario through an Early Researcher Award.

II. PRELIMINARIES

Consider a continuous-time dynamical system

\[ x' = f(x), \quad (1) \]

where \( x \in \mathbb{R}^n \) and \( f : \mathbb{R}^n \rightarrow \mathbb{R}^n \) is assumed to be locally Lipschitz. For each \( x_0 \in \mathbb{R}^n \), we denote the unique solution starting from \( x(0) = x_0 \) and defined on the maximal interval of existence by \( x(t; x_0) \) or simply \( x(t) \) if \( x_0 \) is not emphasized.

Given a scalar \( \delta \geq 0 \), a \( \delta \)-perturbation of the dynamical system (1) is described by the differential inclusion

\[ x' \in F_\delta(x), \quad (2) \]

where \( F_\delta(x) = B_\delta(f(x)) \). An equivalent description of the \( \delta \)-perturbation of system (1) can be given by

\[ x'(t) = f(x(t)) + d(t), \quad (3) \]

where \( d : \mathbb{R} \rightarrow \delta \mathbb{B} \) is any measurable signal. We denote system (1) by \( S \) and its \( \delta \)-perturbation by \( S_\delta \). Note that \( S_\delta \) reduces to \( S \) when \( \delta = 0 \). A solution of \( S_\delta \) starting from \( x(0) = x_0 \) can be denoted by \( x(t; x_0, d) \) or simply \( x(t) \), where \( d \) is a given disturbance signal. The set of all solutions for \( S_\delta \) starting from \( x_0 \) is denoted by \( S_\delta(x_0) \). We are only interested in forward solutions (i.e., solutions defined in positive time) in this paper. Set invariance, defined below and used in this paper, also only concerns forward invariance.

Definition 1 (Invariant set): A set \( \Omega \subseteq \mathbb{R}^n \) is said to be an invariant set of \( S_\delta \) if all solutions of \( S_\delta \) starting in \( \Omega \) remain in \( \Omega \) in positive time.

Definition 2 (Robustly invariant set): A set \( \Omega \subseteq \mathbb{R}^n \) is said to be a \( \delta \)-robustly invariant set of \( S \) if it is an invariant set of \( S_\delta \) for some \( \delta \geq 0 \). It is said to be a robustly invariant set of \( S \) if it is a \( \delta \)-robustly invariant set for some \( \delta > 0 \).

Definition 3 (Robustly safe set): Given an unsafe set \( U \subseteq \mathbb{R}^n \), a set \( W \subseteq \mathbb{R}^n \) is said to be \( \delta \)-robustly safe w.r.t. to \( U \) if all solutions of \( S_\delta \) starting from \( W \) will not enter \( U \).
An immediate connection between robustly safe and invariant sets is the following.

**Proposition 4:** If there exists a $\delta$-robustly invariant set $\Omega$ such that $W \subseteq \Omega$ and $\Omega \cap U = \emptyset$, then $W$ is $\delta$-robustly safe w.r.t. to $U$.

**Definition 5 (Robust barrier function):** Given sets $W, U \subseteq \mathbb{R}^n$, a continuously differentiable function $B : \mathbb{R}^n \to \mathbb{R}$ is said to be a $\delta$-robust barrier function for $W$ and $U$ if the following conditions are satisfied:

1. $B(x) \geq 0$ for all $x \in W$;
2. $B(x) < 0$ for all $U$; and
3. $\nabla B(x) \cdot (f(x) + d) \geq 0$ for all $x$ such that $B(x) = 0$ and $d \in \delta \mathbb{B}$.

**Remark 6:** The choice of sign for $B$ to indicate a safe set is rather arbitrary because we can always negate it. Here we use the condition $B(x) \geq 0$ to describe the safe set (the same as [9] and [14]) instead of $B(x) \leq 0$ (as in the original work [3]).

A $\delta$-robust barrier function for $(W, U)$ provides a certificate for $\delta$-robust safety of $W$ w.r.t. $U$, as summarized in the following result.

**Proposition 7 (Sufficiency of barrier functions [3]):** If there exists a $\delta$-robust barrier function for $(W, U)$, then $W$ is $\delta$-robustly safe w.r.t. $U$.

Several converse theorems for barrier functions have been proved in the literature [1], [2], [13], [14]. We quote a most recent result by Ratschan as follows.

**Theorem 8 (Necessity of barrier functions [14]):** Suppose that the closure of $W$ and $U$ are disjoint and the complement of $U$ is bounded. If $W$ is $\delta$-robustly safe w.r.t. $U$, then there exists a continuously differentiable function $B : \mathbb{R}^n \to \mathbb{R}$ satisfying the following conditions:

1. $B(x) \geq 0$ for all $x \in W$;
2. $B(x) < 0$ for all $U$; and
3. $\nabla B(x) \cdot f(x) > 0$ for all $x$ such that $B(x) = 0$.

While condition (3) appears to be slightly different from item (3) in Definition 5, we will remark on the connections between them, as well as with other variants of barrier function conditions, in Section 11 (see Remark 20).

We say a continuous function $\alpha : [0, a) \to \mathbb{R}$ belongs to class $K$ and write $\alpha \in K$ if $\alpha$ is strictly increasing and $\alpha(0) = 0$.

**Definition 9 (Set stability):** A closed set $A \subseteq \mathbb{R}^n$ is said to be $\delta$-robustly uniformly asymptotically stable ($\delta$-RUAS) for $S$ if the following two conditions are met:

1. For every $\varepsilon > 0$, there exists a $\delta_\varepsilon > 0$ such that $\|x(0)\|_A < \delta_\varepsilon$ implies $\|x(t)\|_A < \varepsilon$ for any solution $x(t)$ of $S$; and
2. There exists some $\rho > 0$ such that, for every $\varepsilon > 0$, there exists some $T > 0$ such that $\|x(t)\|_A < \varepsilon$ for any solution $x(t)$ of $S$ whenever $\|x(0)\|_A < \rho$ and $t \geq T$.

It is not difficult to see that a $\delta$-robustly uniformly asymptotically stable set $A$ must be $\delta$-robustly invariant.

**Definition 10 (Robust Lyapunov function):** Let $D \subseteq \mathbb{R}^n$ be an open set containing a closed set $A \subseteq \mathbb{R}^n$. A continuously differentiable function $V : D \to \mathbb{R}$ is said to be a $\delta$-robust Lyapunov function for $S$ w.r.t. $A$ if the following two conditions are satisfied:

1. there exist class $K$ functions $\alpha_1$ and $\alpha_2$ such that $\alpha_1(\|x\|_A) \leq V(x) \leq \alpha_2(\|x\|_A)$ for all $x \in D$; and
2. there exists a class $K$ functions $\alpha_3$ such that $\nabla V(x) \cdot (f(x) + d) \leq -\alpha_3(\|x\|_A)$ for all $x \in D$ and $d \in \delta \mathbb{B}$.

There are well-known Lyapunov characterizations of set stability.

**Theorem 11 (Lyapunov characterization of set stability [10], [17]):** A closed set $A \subseteq \mathbb{R}^n$ is $\delta$-RUAS for $S$ if and only if there exists a $\delta$-robust Lyapunov function for $S$ w.r.t. $A$.

### III. ROBUST CONVERSE BARRIER FUNCTIONS VIA LYAPUNOV FUNCTIONS

In this section, we prove a version of converse barrier function theorem by resorting to Lyapunov theory.

We first introduce some notation. Let $R_\delta^S(x_0)$ denote the set reached by solutions of $S_\delta$ at time $t$ starting from $x_0$, i.e.,

$$R_\delta^S(x_0) = \{x(t) : x(\cdot) \in S_\delta(x_0)\}.$$  

We further define $R_\delta(x_0) = \bigcup_{t \geq 0} R_\delta^S(x_0)$, and, for a set $W \subseteq \mathbb{R}^n$, $R_\delta^S(W) = \bigcup_{x_0 \in W} R_\delta^S(x_0)$, $R_\delta(W) = \bigcup_{x_0 \in W} R_\delta(x_0)$.

Clearly, $R_\delta(W)$ is a $\delta$-robustly invariant set of $S$. If $W$ is $\delta$-robustly safe, then $R_\delta(W) \cap U \neq \emptyset$. If the complement of $U$ is bounded (as assumed in Theorem 8), then $R_\delta(W)$ is bounded. Let $\Omega = R_\delta^S(W)$. Then $\Omega$ is compact. Without further assumption, $\Omega$ may intersect with $U$ as shown in the following example.

**Example 12:** Consider $S$ defined by $x' = -x$. Let $W = [-0.1, 0.1]$ and $\delta = 0.2$. Then $R_\delta(W) = (-0.2, 0.2)$ and $\Omega = [-0.2, 0.2]$. If $U = (-\infty, -2] \cup [2, \infty)$, then $W$ is $\delta$-robustly safe w.r.t. $U$ because $R_\delta(W) \cap U = \emptyset$. Yet $\Omega \cap U \neq \emptyset$.

Note that the assumptions of Theorem 8 are indeed satisfied by the example above. While additionally assuming $U$ to be open will lead to $\Omega \cap U = \emptyset$, we need a slightly stronger assumption for the purpose of this section, that is, $\Omega \cap \overline{U} = \emptyset$. This is summarized in the following assumption.

**Assumption 13:** The set $W$ is $\delta$-robustly safe w.r.t. $U$ and $\Omega \cap \overline{U} = \emptyset$, where $\Omega = R_\delta^S(W)$. Furthermore, either $\Omega$ is compact or $f$ is globally Lipschitz.

With this assumption, we prove the following result on converse barrier functions.

**Theorem 14 (Robustly safe sets admit robust barrier functions):** Suppose that Assumption 13 holds. Then for any $\delta' \in (0, \delta)$, there exists a $\delta'$-robust barrier function for $(W, U)$.

The conclusion of the above result is slightly stronger than the main result in [14] (quoted as Theorem 8 in Section 11 above) in two aspects: (1) we show the existence of a $\delta'$-robust barrier function for any $\delta' \in (0, \delta)$; (2) we do not assume $\Omega$...
to be compact, when \( f \) is globally Lipschitz.\(^4\) Assumption \([13]\) appears to be stronger than that of Theorem \([8]\) in that it requires \( \Omega \cap \overline{U} = \emptyset \). Nonetheless, the proof of Theorem \([8]\) (see, e.g., Lemma 5 in \([13]\)) seems to be using this fact without explicitly mentioning or proving it. Example \([12]\) above shows that this does not readily follow from the assumptions of Theorem \([8]\).

Despite these subtle technical differences, the main message of this section, however, is that converse barrier functions can be constructed from Lyapunov functions.

The construction relies on showing that the closure of the reachable set of the robustly safe set, i.e., the set \( \Omega = \overline{R}_0(W) \), is robustly asymptotically stable (Theorem \([17]\)). The following technical lemma on reachable sets of a perturbed system plays an important role in proving Theorem \([17]\).

**Lemma 15:** Fix any \( \delta' \in (0, \delta) \) and \( \tau > 0 \). Let \( K \subseteq \mathbb{R}^n \) be a compact set. Then there exists some \( \tau = r(K, \delta', \delta) > 0 \) such that the following holds: if there is a solution \( x \) of \( S_{\delta'} \) such that \( x(s) \in K \) for all \( s \in [0, T] \), where \( T \geq \tau \), then for any \( y_0 \in B_r(x(0)) \) and any \( y_1 \in B_r(x(T)) \), we have \( y_1 \in R_\delta(y_0) \), i.e., \( y_1 \) is reachable at \( T \) from \( y_0 \) by a solution of \( S_\delta \). Furthermore, if \( f \) is globally Lipschitz, \( r \) can be chosen to be independent of \( K \).

**Proof:** Let \( y(s) = x(s) + \frac{s}{T}(y_1 - x_1 + (x_0 - y_0)) + (y_0 - x_0) \), \( s \in [0, T] \). Then \( y(0) = y_0 \) and \( y(T) = y_1 \). Furthermore,
\[
\|y(s) - x(s)\| \leq \|y_1 - x_1\| + \frac{s}{T}\|y_0 - x_0\| \leq r\left(\frac{s}{T} + 1 - \frac{s}{T}\right) = r,
\]
and
\[
\|y'(s) - x'(s)\| \leq \frac{1}{T}\|y_1 - x_1 + (x_0 - y_0)\| \leq \frac{2r}{T},
\]
for all \( s \in [0, T] \). Hence
\[
\|y'(s) - f(y(s))\| = \|y'(s) - x'(s) + x'(s) - f(x(s)) + f(x(s)) - f(y(s))\| \leq \frac{2r}{T} + \delta' + Lr,
\]
where we used the triangle inequality, the fact that \( x \) is a solution of \( S_{\delta'} \), and Lipschitz continuity of \( f \) on the set \( B_r(K) \). By picking \( r \) sufficiently small such that \( \frac{2r}{T} + \delta' + Lr < \delta \), then we have \( \|y'(s) - f(y(s))\| < \delta \) for all \( s \in [0, T] \). Thus \( y \) is a solution of \( S_\delta \) and the conclusion follows. Note that the choice of \( r \) only depends on \( K, \tau, \delta' \), and \( \delta \). The dependence on \( K \) is removed if \( f \) is globally Lipschitz.\[\]\[\]

**Remark 16:** Lemma \([15]\) extends the statement of Lemma 1 in \([14]\), where the proof was omitted. Lemma \([15]\) is slightly stronger because it says that we can steer any point in a small neighborhood of \( x(0) \) (as opposed to only \( x(0) \)) to a small neighborhood of \( x(T) \). This fact is needed in the proof of Theorem \([17]\) below. Lemma \([15]\) also allows \( T \) to vary as long as it is lower bounded by \( \tau \). The proof given here is elementary and constructive. Similar argument (of a simpler version) appeared in the proof of Theorem 1 in \([18]\).

**Theorem 17 (Robustly invariant sets are robustly asymptotically stable):** If Assumption \([13]\) holds, then for any \( \delta' \in (0, \delta) \), the set \( \Omega = \overline{R}_\delta(W) \) is \( \delta' \)-RUAS for \( S \).

**Proof:** We verify conditions (1) and (2) of Definition \([9]\).
(1) For any \( \varepsilon > 0 \), let \( \tau > 0 \) be the minimal time that is required for solutions of \( S_{\delta'} \) to escape from \( B_\frac{r}{2}(S) \) to \( B_\frac{r}{2}(\Omega) \). The existence of such \( \tau \) follows from that \( f \) is locally Lipschitz and an argument using Gronwall’s inequality. Pick \( \delta_x < \min(r, \frac{r}{2}) \), where \( r \) is from Lemma \([15]\) applied to the set \( B_r(\Omega) \) and scalars \( \tau, \delta' \), and \( \delta \). Let \( x \) be any solution of \( S_{\delta'} \) such that \( \|x(0)\|_\Omega < \delta_x \). We show that \( \|x(t)\|_\Omega < \varepsilon \) for all \( t \geq 0 \). Suppose that this is not the case. Then \( \|x(t_1)\|_\Omega \geq \varepsilon \) for some \( t_1 \geq \tau > 0 \). Since \( \delta_x < r \), we can always pick \( y_0 \in B_\frac{r}{2}(S) \) such that \( y_0 \in B_r(x(0)) \) by the triangle inequality. By Lemma \([15]\) there exists a solution of \( S_\delta \) from \( y_0 \in R_\delta(W) \) to \( x(t_1) \notin \Omega \). This contradicts that \( R_\delta(W) \) is \( \delta \)-robustly invariant.
(2) Fix any \( \varepsilon_0 > 0 \). Following part (1), choose \( \delta_x \) such that \( \|x(0)\|_\Omega < \delta_x \) implies \( \|x(t)\|_\Omega < \varepsilon_0 \) for any solution \( x(t) \) of \( S_{\delta'} \). Let \( r \) be chosen according to Lemma \([15]\) with the set \( B_\frac{r}{2}(\Omega) \) and scalars \( \tau, \delta' \), and \( \delta \). Choose \( \rho \in (0, r) \). Let \( x \) be any solution of \( S_{\delta'} \). We show that \( \|x(0)\|_\Omega < \rho \) implies that \( x(t) \in R_\delta(W) \) for all \( t \geq 1 \). Suppose that this is not the case. Then there exists some \( t_1 \geq 1 \) such that \( x(t_1) \in \partial \Omega \) or \( x(t_1) \notin \Omega \). In either case, we can pick \( y_1 \in B_\frac{r}{2}(x(t_1)) \) such that \( y_1 \notin \Omega \) and \( y_0 \in B_r(x(0)) \) such that \( y_0 \in R_\delta(W) \). By Lemma \([15]\) there exists a solution of \( S_\delta \) from \( y_0 \in R_\delta(W) \) to \( y_1 \notin \Omega \). This contradicts that \( R_\delta(W) \) is \( \delta \)-robustly invariant. Hence \( x(t) \in R_\delta(W) \subseteq \Omega \) for all \( t \geq 1 \). This clearly implies (2).\[\]

The conclusion of Theorem \([17]\) cannot be strengthened in the sense that the set \( \Omega = \overline{R}_\delta(W) \) may not be \( \delta \)-RUAS for \( S \) as shown in the simple example below.

**Example 18:** Consider \( S \) defined by \( -x - x^2 \). Let \( W = [-0.1, 0.1] \) and \( \delta = 0.25 \). Then \( R_0(W) = (-0.25, 0.25) \) and \( \Omega = [-0.25, 0.25] \). Solutions of \( S_\delta \) starting from \( x_0 = 0.25 + \varepsilon \), where \( \varepsilon > 0 \), with \( d(t) = \delta \) will tend to infinity. Hence \( \Omega \) cannot be \( \delta \)-RUAS.

**Theorem 14** can be obtained as a corollary of Theorem \([17]\) and Theorem \([11]\).

**Proof of Theorem \([17]\):** By Theorem \([17]\) \( \Omega \) is \( \delta' \)-RUAS for any \( \delta' \in [0, \delta] \). By Theorem \([11]\) there exists a neighborhood \( D \) of \( \Omega \) and a smooth \( V \) : \( D \to \mathbb{R} \) such that \( V \) satisfies conditions (1) and (2) in Definition \([10]\). Define
\[
B(x) = -V(x), \quad x \in D.
\]
It is straightforward to verify that \( B \) satisfies conditions (1)-(3) of Definition \([8]\) for a \( \delta' \)-robust barrier function.\[\]

**Remark 19:** The construction of a Barrier function via a Lyapunov function is inspired by the work \([10]\) (see also \([9]\)) and \([14]\). In \([10]\), the authors showed that if there exists of a barrier function \( B : \mathbb{R}^n \to \mathbb{R} \) satisfying the condition
\[
\nabla B(x) \cdot (f(x)) \geq -\alpha(B(x)), \quad \forall x \in D,
\]
for some open set $D$ containing $C = \{x \in \mathbb{R}^n : B(x) \geq 0\}$ and extended class $\mathcal{K}$ function\(^2\) $\alpha$, then $C$ is asymptotically stable. This is straightforward to see because one can construct a Lyapunov function based on $B$ by $V(x) = 0$ if $x \in C$ and $V(x) = -B(x)$ if $x \in D \backslash C$. The authors of \cite{10} also discussed robustness implied by condition \cite{4}. The results of this section can be seen as a converse fact. We start with the assumption that a set $X$ is never positive by this construction. Nonetheless, condition (7) does in a compact neighborhood of the closure of the robustly invariant reachable set $\Omega = \overline{R}(W)$ is robustly asymptotically stable. Our proof of the latter fact is inspired by the work in \cite{14}. A converse Lyapunov function is then used to construct a robust barrier function.

Remark 20: Condition (3) in Definition 5 for a barrier function has different variants. The original work \cite{5} had a condition like (3) and the following variant

$$\nabla B(x) \cdot f(x, d) \geq 0, \quad \forall (x, d) \in \mathcal{X} \times \mathcal{W},$$

where $\mathcal{X} \times \mathcal{W}$ is the set on which $f$ is defined and $\mathcal{W}$ is an arbitrary disturbance set. According to \cite{3}, this variant makes the set of functions satisfying the barrier function conditions convex and amenable to computation by convex optimization. Condition (5) appears to be restrictive (from a computational perspective) because it needs to be satisfied for all $(x, d) \in \mathcal{X} \times \mathcal{W}$. The authors of \cite{9} proposed (4) as a variant. Following the construction $B(x) = -V(x)$ in the proof of Theorem \cite{14} we have

$$\nabla B(x) \cdot (f(x) + d) = -\nabla V(x) \cdot (f(x) + d) \geq \alpha_3(\|x\|_A) \geq \alpha_3(\alpha_2^{-1}(V(x))) = \alpha_3(\alpha_2^{-1}(-B(x))),$$

for all $x \in D$ and $d \in \delta \mathbb{R}$. Defining $\alpha_0(s) = -\alpha_3(\alpha_2^{-1}(-s))$, we obtain

$$\nabla B(x) \cdot (f(x) + d) \geq -\alpha_0(B(x)), \quad \forall (x, d) \in D \times \delta \mathbb{R}.$$ \hspace{1cm} (7)

While in the absence of disturbance \cite{7} appears in the same form as \cite{4}, it has a subtle difference because $\alpha_0(s)$ in \cite{7} is not defined for $s > 0$. Note that, since $B(x) = -V(x)$, $B(x)$ is never positive by this construction. Nonetheless, \cite{7} does match \cite{4} when $B(x) \leq 0$ in the absence of disturbance. A variant of \cite{7} can be obtained by letting

$$B_c(x) = c - V(x),$$

where $c > 0$ is a scalar such that $B_c(x) \geq 0$ implies $x \not\in U$. For instance, one can take $c$ be the maximum value of $V(x)$ in a compact neighborhood of $\Omega$ that does not overlap with $U$. Then $B_c(x)$ also verifies all the conditions of a $\delta'$-robust barrier function. In particular, \cite{6} becomes

$$\nabla B_c(x) \cdot (f(x) + d) \geq \alpha_3(\alpha_2^{-1}(c - B_c(x))) = -\alpha(B_c(x))$$

with $\alpha_0(s) = -\alpha_3(\alpha_2^{-1}(c - s))$. Note that $B_c(x)$ now can take positive value and $\alpha_0(s)$ is defined for $s \in (0, c)$ as well. Nonetheless, while \cite{9} agrees with \cite{4} for $B_c(x) \leq 0$ in the absence of disturbance, it is in fact stronger than \cite{4}. When $B_c(x) > 0$ because $\alpha_0(s) < 0$ for $s \in (0, c)$. This is not surprising because $B_c(x)$ is constructed using a Lyapunov function. By condition \cite{9}, when $B_c(x) = 0$, we obtain

$$\nabla B_c(x) \cdot (f(x) + d) \geq \alpha_3(\alpha_2^{-1}(c) > 0.$$ \hspace{1cm} (10)

In the absence of disturbance $d$, this recovers condition (3) for the barrier function in Theorem 8. The author of \cite{14} seems to be using this strict positiveness, as well as strict positiveness of $B$ on $W$, to indicate a robust barrier certificate.

Here we formally define a robust barrier function by requiring condition (3) in Definition 5 (or even \cite{10}) to hold with under disturbance. This is in fact the case in the original definition \cite{3}. We also remark that, when the set $B(x) = 0$ is compact, condition (3) in Theorem 8 also holds under sufficiently small disturbance. The construction given by Theorem \cite{14} however, allows any disturbance of size $\delta' \in [0, \delta)$.

Remark 21: Another commonly used class of barrier functions is called reciprocal barrier functions \cite{9}, inspired by barrier methods from optimization \cite{19}. Given a set $C$ defined by

$$C = \{x \in \mathbb{R}^n : h(x) \geq 0\},$$

where $h : \mathbb{R}^n \rightarrow \mathbb{R}$ is a continuously differentiable function, a reciprocal barrier function $B : C^o \rightarrow \mathbb{R}$, where $C^o = \{x \in \mathbb{R}^n : h(x) > 0\}$ is the interior of $C$, such that

$$\frac{1}{\alpha_1(h(x))} \leq B(x) \leq \frac{1}{\alpha_2(h(x))},$$

$$\nabla B(x) \cdot f(x) \leq \alpha_3(h(x)),$$

for all $x \in C^o$, where $\alpha_i$ ($i = 1, 2, 3$) are class $\mathcal{K}$ functions. The reciprocal of the construction of barrier functions based on Lyapunov function directly gives a reciprocal barrier function. Let $h(x) = c - V(x)$ as in \cite{8} and $B(x) = \frac{1}{t}$. Then it is straightforward to verify that \cite{11} is satisfied and \cite{12} is robustly satisfied.

IV. DISCRETE-TIME CONVERSE BARRIER FUNCTIONS

Having built a link between Lyapunov functions and barrier functions, we extend the results in the previous section to the discrete-time setting and provide a converse theorem for discrete-time barrier function. The presentation parallels that of Section III but formulated for discrete-time systems. We first present the preliminaries for discrete-time systems.

A. Preliminaries on discrete-time systems

Consider a discrete-time dynamical system

$$x(t + 1) = f(x(t)),$$

where $x(t) \in \mathbb{R}^n$ for $t \in \mathbb{Z}^+ \{0, 1, 2, \ldots\}$ and $f : \mathbb{R}^n \rightarrow \mathbb{R}^n$ is assumed to be locally Lipschitz.

Given a scalar $\delta \geq 0$, a $\delta$-perturbation of the dynamical system \cite{13} is described by the difference inclusion

$$x(t + 1) \in F_\delta(x(t)),$$

where $F_\delta(x) = B_r(f(x))$, or equivalently

$$x(t + 1) = f(x(t)) + d(t),$$

where $d(t) \in B_r(0)$.
where $d(t) \in \mathbb{B}$ for each $t$. We denote system (\ref{eq:system}) by $DTS$ and its $\delta$-perturbation by $DTS_{\delta}$. Note that $DTS_{\delta}$ reduces to $DTS$ when $\delta = 0$. A solution of $DTS_{\delta}$ is a sequence denoted by $x(t; x_0, d)$ or $x(t)$, where $t = 0, 1, 2, \cdots$ and $d(t)$ is a disturbance sequence.

Since robustly safe sets, robustly invariant sets, and robust stability w.r.t. a closed set for $DTS$ can be defined almost verbatim as for continuous-time systems, by replacing solutions of $S_\delta$ with that of $DTS_{\delta}$, they are omitted. We define discrete-time barrier and Lyapunov functions as follows.

**Definition 22 (Discrete-time robust barrier function):** Given sets $W, U \subseteq \mathbb{R}^n$, a continuously differentiable function $B : \mathbb{R}^n \to \mathbb{R}$ is said to be a $\delta$-robust barrier function for $W$ and $U$ if the following conditions are satisfied:

1. $B(x) \geq 0$ for all $x \in W$;
2. $B(x) < 0$ for all $U$; and
3. $B(f(x) + d) \geq 0$ for all $x$ such that $B(x) \geq 0$ and all $d \in \mathbb{B}$.

**Proposition 23 ( Sufficiency of discrete-time barrier functions):** If there exists a $\delta$-robust barrier function for $(W, U)$, then $W$ is $\delta$-robustly safe w.r.t. $U$.

**Proof:** The conclusion follows from the fact that the set $C = \{x \in \mathbb{R}^n : B(x) \geq 0\}$ is $\delta$-robustly invariant and $C \cap U \neq \emptyset$. \hfill \Box

**Remark 24:** Condition (3) in Definition 22 for a discrete-time barrier function appears to be weaker than the ones used in practice. For instance, the following condition was proposed in (8):

$$B(f(x)) - B(x) \geq -\alpha(B(x)), \quad x \in D,$$

where $D \supseteq C = \{x \in \mathbb{R}^n : B(x) \geq 0\}$ and $\alpha$ is class $K$ function satisfying $\alpha(r) < r$ when $r > 0$. Note that one needs to extend the definition of $\alpha$ to $(-b, 0)$ for some $b > 0$ if the set $D$ contains $x$ such that $B(x) < 0$. A special case of (6) is given by $\alpha(r) = \eta r^p$ for $\eta \in (0, 1)$. When $\eta = 1$ and $D = C$, we obtain condition (3) of Definition 22 when $\eta = 0$, we obtain a condition that is stronger than (16) on $C$:

$$B(f(x)) - B(x) \geq -\alpha(B(x)), \quad x \in D,$$

which clearly implies (16) for any $\alpha \in K$ and $D = C$ because $\alpha(B(x)) \geq 0$ for $B(x) \geq 0$. Similar to Remark 20 on continuous-time barrier functions, the construction of discrete-time converse barrier functions by Lyapunov functions below in fact satisfy an even stronger form

$$B(f(x)) - B(x) \geq -\alpha(x)(B(x)), \quad x \in D,$$

where $D$ is an open neighborhood of $C$ and $\alpha(x)(s) \leq 0$ for all $s$ in its domain. Clearly, (18) implies both (17) and (16).

**Definition 25:** Let $D \subseteq \mathbb{R}^n$ be an open set containing a closed set $A \subseteq \mathbb{R}^n$. A continuously differentiable function $V : D \to \mathbb{R}$ is said to be a $\delta$-robust Lyapunov function for $DTS$ w.r.t. $A$ if the following two conditions are satisfied:

1. there exist class $K$ functions $\alpha_1$ and $\alpha_2$ such that
   $$\alpha_1(||x||_A) \leq V(x) \leq \alpha_2(||x||_A)$$
   for all $x \in D$; and
2. there exists a class $K$ functions $\alpha_3$ such that
   $$V(f(x) + d) - V(x) \leq -\alpha_3(||x||_A)$$
   for all $x \in D$ and $d \in \mathbb{B}$.

There are also Lyapunov characterizations of set stability for discrete-time systems.

**Theorem 26 (Lyapunov characterization of set stability for $DTS$):** A closed set $A \subseteq \mathbb{R}^n$ is $\delta$-RUAS for $DTS$ if and only if there exists a $\delta$-robust Lyapunov function for $DTS$ w.r.t. $A$.

**B. Converse barrier functions via Lyapunov functions for discrete-time systems**

The notion and definitions for reachable sets remain the same, with continuous-time solutions replaced with discrete-time ones. We define $R^d_\delta(x_0), R_\delta(x_0), R_\delta(W)$ and $\Omega = \bar{R}_\delta(W)$ as in Section 11 replacing continuous-time solutions with discrete-time ones. The following is a discrete-time version of Lemma 15.

**Lemma 27:** Fix any $\delta' \in (0, \delta)$. Let $K \subseteq \mathbb{R}^n$ be a compact set. Then there exists some $r = r(K, \delta', \delta) > 0$ such that the following holds: if there is a solution $x$ of $S_{\delta'}$ such that $x(s) \in K$ for all $s \in [0, T)$, then $T \geq 1$, then for any $y_0 \in B_r(x(0))$ and any $y_1 \in B_r(x(T))$, we have $y_1 \in R^d_\delta(y_0)$, i.e., $y_1$ is reachable at $T$ from $y_0$ by a solution of $S_\delta$. Furthermore, if $f$ is globally Lipschitz, $r$ can be chosen to be independent of $K$.

**Proof:** Let $y(s) = x(s) + \frac{s}{T}(y_1 - x_1 + (x_0 - y_0)) + (y_0 - x_0)$,

for $s \in \{0, 1, \cdots, T\}$. Then $y(0) = y_0$ and $y(T) = y_1$. Furthermore,

$$\|y(s) - x(s)\| \leq \|y_1 - x_1\| \frac{s}{T} + \|y_0 - x_0\| (1 - \frac{s}{T}) \leq \frac{r}{T} + \delta' + Lr, \quad s \in \{0, 1, \cdots, T - 1\},$$

where we used the triangle inequality, the fact that $x$ is a solution of $S_{\delta'}$, and Lipschitz continuity of $f$ on the set $B_r(K)$. By picking $r$ sufficiently small such that $r + \delta' + Lr < \delta$, then we have $\|y(s+1) - f(y(s))\| < \delta$ for all $s \in \{0, 1, \cdots, T - 1\}$. Thus $y$ is a solution of $DTS_{\delta}$ and the conclusion follows. Note that the choice of $r$ only depends on $K, \delta'$, and $\delta$. If $f$ is globally Lipschitz, the dependence on $K$ can be removed. \hfill \Box

The following is a discrete-time version of Theorem 17.

**Theorem 28 (Robustly invariant sets are robustly asymptotically stable):** If Assumption 13 holds, then $\Omega$ is $\delta'$-RUAS for $DTS$ for any $\delta' \in (0, \delta)$.

**Proof:** (1) For any $\varepsilon > 0$, let $r \epsilon$ be from Lemma 27 applied to the set $B_\varepsilon(\Omega)$ and scalars $\delta'$ and $\delta$. Pick $\delta = r$. Let
Let $x$ be any solution of $DTS_{\delta'}$, such that $\|x(t)\|_{Q} < \delta_c$. We show that $\|x(t)\|_{Q} < \varepsilon$ for all $t \geq 0$. Suppose that this is not the case. Then $\|x(k)\|_{Q} \geq \varepsilon$ for some $k \geq 1$. Since $\|x(0)\|_{Q} < r$, we can always pick $y_0 \in R_q(W)$ such that $y_0 \in B_r(x(0))$ by the triangle inequality. By Lemma 27, there exists a solution of $DTS_{\delta'}$ from $y_0 \in R_q(W)$ to $x(k) \not\in \Omega$. This contradicts that $R_q(W)$ is $\delta$-robustly invariant.

(2) Fix any $\varepsilon_0 > 0$. Following part (1), choose $\delta_{\varepsilon_0}$ such that $\|x(t)\|_{Q} < \delta_{\varepsilon_0}$ implies $\|x(t)\|_{Q} < \varepsilon_0$ for any solution $x(t)$ of $DTS_{\delta'}$. Let $r$ be chosen according to Lemma 27 with the set $B_{\varepsilon_0}(\Omega)$ and scalars $\delta'$ and $\delta$. Choose $\rho \in (0, r)$. Let $x$ be any solution of $DTS_{\delta'}$. We show that $\|x(0)\|_{A} < \rho$ implies that $x(t) \in R_q(W)$ for all $t \geq 1$. Suppose that this is not the case. Then there exists some $k \geq 1$ such that $x(k) \not\in \partial \Omega$ or $x(k) \not\in \Omega$. In either case, we can pick $y_1 \in B_r(x(k))$ such that $y_1 \not\in \Omega$ and $y_0 \in B_r(x(0))$ such that $y_0 \in R_q(W)$. By Lemma 27, there exists a solution of $DTS_{\delta'}$ from $y_0 \in R_q(W)$ to $y_1 \not\in \Omega$. This contradicts that $R_q(W)$ is $\delta$-robustly invariant. Hence $x(t) \in R_q(W)$ for all $t \geq 1$. This completes part (2) of the definition of $\delta'$-RUAS.

Theorem 29 (Robustly safe sets admit robust discrete-time barrier functions): Suppose that Assumption 13 holds. If either $\Omega$ is compact or $f$ is globally Lipschitz, then for any $\delta' \in (0, \delta)$, there exists a $\delta'$-robust barrier function for $(W, U)$.

Proof: By Theorem 28, $\Omega$ is $\delta'$-RUAS for $DTS$ with any $\delta' \in (0, \delta)$. By Theorem 26, there exists a neighborhood $D$ of $\Omega$ and a smooth $V : D \to \mathbb{R}$ such that

$$
\alpha_1(\|x\|_Q) \leq V(x) \leq \alpha_2(\|x\|_Q),
$$

and

$$
V(f(x) + d) - V(x) \geq -\alpha_3(\|x\|_Q),
$$

for all $x \in D$ and $d \in \delta' B$, where $\alpha_i (i = 1, 2, 3)$ are class $C$ functions. Define

$$
B(x) = -V(x), \quad x \in D.
$$

It is straightforward to verify that $B$ satisfies conditions (1)-(3) of Definition 22 for a $\delta'$-robust discrete-time barrier function.

Remark 30: By the construction of the barrier function $B(x)$ in the proof of Theorem 29, we in fact have a stronger condition than condition (3) in Definition 22:

$$
B(f(x) + d) - B(x) \geq -\alpha(B(x)),
$$

for all $x \in D$ and $d \in \delta' B$, where $\alpha$ is defined and increasing on $(-a, 0)$ for some $a > 0$ and $\alpha(0) = 0$.

Remark 31: Similar to Remark 21, we can construct discrete-time reciprocal barrier functions via Lyapunov functions. A discrete-time reciprocal barrier function $B : C^0 \to \mathbb{R}$ satisfies

$$
\frac{1}{\alpha_1(h(x))} \leq B(x) \leq \frac{1}{\alpha_2(h(x))},
$$

$$
B(f(x)) - B(x) \leq \alpha_3(h(x)),
$$

for all $x \in C^0$, where $C^0$ is the interior of the set $C = \{ x \in \mathbb{R}^n : h(x) \geq 0 \}$ for some continuously differentiable function $h : \mathbb{R}^n \to \mathbb{R}$. Clearly, $h(x) = c - V(x)$ for some sufficiently small $c > 0$ and $B(x) = \frac{1}{x}$ satisfy the above conditions robustly.

V. Conclusions

In this paper, we established a connection between Lyapunov functions and barrier functions. We proved that for all robustly safe dynamical systems, the closure of the robust reachable set of the robustly safe set must be robustly asymptotically stable. The converse Lyapunov function theory can then be brought to bear to yield a robust barrier function. We made remarks on several variants of the barrier function conditions and showed that they can all be satisfied by the construction of barrier functions using Lyapunov functions. We also formulated the results for discrete-time in a similar fashion.

For future work, it would be interesting to investigate how the viewpoint of robust barrier functions via Lyapunov functions can be utilized in practice. Potentially all the computational techniques for searching Lyapunov functions can be used for searching barrier functions. The key technical challenge, however, seems to be that, while safety requirements can be specified rather arbitrarily by a designer (e.g., by defining the unsafe region $U$ and safe initial region $W$ in this paper), the barrier function conditions are only met at the boundary of reachable set from the safe initial region $W$, if this set $W$ can indeed be certified to be safe. While the computing of reachable sets can be highly nontrivial, it would be interesting to investigate whether the adaptive refinement techniques for computing maximal controlled invariant sets (see, e.g., 21), combined with computational techniques for constructing barrier functions (see, e.g., 22), can be used to determine a smaller set on which (control) barrier functions can be algorithmically constructed. A related theoretical question is that whether such procedures can be approximately complete in the sense that any $\delta'$-robustly safe sets admit a computable $\delta'$-robust barrier certifications for any $\delta' \in [0, \delta)$. In view of the results of this paper, such questions can hopefully be answered in a unified fashion in regard to Lyapunov functions for set stability and barrier functions for safety.
