Abstract: We propose a study of a distribution registration model for general deformation functions. In this framework, we provide estimators of the deformations as well as a goodness of fit test of the model. For this, we consider a criterion which studies the Fréchet mean (or barycenter) of the warped distributions whose study enables to make inference on the model. In particular we obtain the asymptotic distribution and a bootstrap procedure for the Wasserstein variation.

AMS 2000 subject classifications: Primary 60K35, 60K35; secondary 60K35.

1. Introduction

Giving a sense to the notion of mean behaviour may be counted among the very early activities of statisticians. When confronted to large data sample, the usual notion of Euclidean mean is too rough since the information conveyed by the data possesses an inner geometry far from the Euclidean one. Indeed, deformations on the data such as translations, scale location models for instance or more general warping procedures prevent the use of the usual methods in data analysis. This problem arises naturally for a wide range of statistical research fields such as functional data analysis for instance Ramsay and Silverman (2005), Bercu and Fraysse (2012) and references therein, image analysis in Trouvé and Younes (2005) or Amit, Grenander and Piccioni (1991), shape analysis in Kendall et al. (1999), Grenander (1994) or Huckemann, Hotz and Munk (2010), with many applications ranging from biology in Bolstad et al. (2003) to pattern recognition Sakoe and Chiba (1978) just to name a few.

The same kind of issues arises when considering the estimation of distribution functions observed with deformations. This situation occurs often in biology, for
example when considering gene expression. However, when dealing with the registration of warped distributions, the literature is scarce. We mention here the method provided for biological computational issues known as quantile normalization in Bolstad et al. (2003) and the related work Gallón, Loubes and Maza (2013). Very recently using optimal transport methodologies, comparisons of distributions have been studied using a notion of Fréchet mean for distributions, see for instance in Agueh and Carlier (2011) or a notion of depth as in Chernozhukov et al. (2014).

Actually the observations are said to come from a deformation model if they can be written as

\[ X_{i,j} = \left( \varphi_j^* \right)^{-1}(\varepsilon_{i,j}), \]

for \( j = 1, \ldots, J \) where \( (\varepsilon_{i,j}) \) defined for all \( 1 \leq i \leq n, 1 \leq j \leq J \) are i.i.d. random variables with unknown distribution \( \mu \) and for deformation functions \( \varphi_j^* \). This model is the natural extension of the functional deformation models studied in the statistical literature for which estimation procedures are provided in Gamboa, Loubes and Maza (2007) while testing issues are tackled in Collier and Dalalyan (2015). Within this framework, statistical inference on deformation models for distributions have been studied first in Czado and Munk (1998), Munk and Czado (1998) and Freitag and Munk (2005), where tests are provided in the case of parametric functions, while the estimation of the parameters is studied in Agulló-Antolín et al. (2015).

In this work, after recalling the model we use in Section 2, we tackle the problem of providing a goodness of fit test in a general non parametric deformation model. For this, we will use an alignment criterion with respect to the Wasserstein’s barycenter of a deformation of the observed distributions. This requires an equivalent of a central limit theorem for the Wasserstein variation of a barycenter of measures in both the general case in Section 3 and under the null assumption (observations are drawn from the deformation model) in Section 4. We obtain the asymptotic distribution of the matching criterion in both cases, with a different normalization under the null assumption (only for the parametric case). For this, we will need to build estimates of the deformation parameters with respect to this particular alignment criterion and study their behavior in Section 4.1. Finally testing procedures are given in Section 5. They rely on the estimation of the quantiles of the empirical process of the Wasserstein’s variation which is obtained using a bootstrap procedure proved in Section 5.1. Proofs are postponed to Section 6.

2. A deformation model for distributions

Assume we observe \( J \) samples of \( n \) i.i.d random variables \( X_{i,j} \) with distribution \( \mu_j \), associated to a distribution function \( F_j : (e_j, d_j) \mapsto (0, 1) \) with density with respect to the Lebesgue measure \( f_j \). Let \( \mu_{n,j} \) and \( F_{n,j} \) be the empirical measure and empirical distribution function associated to the sample \( (X_{i,j})_{1 \leq i \leq n} \).

Our aim is to test the existence of a distribution’s deformation model, in the sense that all the distributions \( \mu_j \) would be warped from an unknown distribu-
tion template $\mu$ by a deformation function $\varphi_j^\star$. More precisely, consider a family of warping functions $G = G_1 \times \cdots \times G_J$ such that

For all $h \in G_j$, $h : (c_j, d_j) \to (a, b) \quad x \mapsto h(x)$ is invertible, increasing, 

and s.t. $-\infty \leq a < b \leq +\infty$, \quad $-\infty \leq c \leq c_j < d_j \leq d \leq +\infty$.

We would like to build a goodness-of-fit testing procedure for the following model

There exist $(\varphi_j^\star, \ldots, \varphi_J^\star) \in G$ and $(\varepsilon_{i,j})_{1 \leq i \leq n, 1 \leq j \leq J}$ i.i.d. such that

$X_{i,j} = (\varphi_j^\star)^{-1}(\varepsilon_{i,j}) \quad \forall 1 \leq j \leq J$ \hspace{1cm} (H)

Denote by $G$ the distribution function of $\varepsilon$ with law $\mu$ with support $(a, b)$, while $G_{n,j}$ is the corresponding empirical version.

Our criterion will be based on the Wasserstein distance $W^2_2$ since this distance is well suited to compared deformations between distributions. For $d \geq 1$, consider the following set

$W_2^2(\mathbb{R}^d) = \{P \text{ probability on } \mathbb{R}^d \text{ with finite second moment} \}$.

For two probabilities $\mu$ and $\nu$ in $W_2^2(\mathbb{R}^d)$, we denote by $\Pi(\mu, \nu)$ the set of all probability measures $\pi$ over the product set $\mathbb{R}^d \times \mathbb{R}^d$ with first (resp. second) marginal $\mu$ (resp. $\nu$).

The transportation cost with quadratic cost function, or quadratic transportation cost, between these two measures $\mu$ and $\nu$ is defined as

$T_2(\mu, \nu) = \inf_{\pi \in \Pi(\mu, \nu)} \int \|x - y\|^2 d\pi(x, y)$.

The quadratic transportation cost allows to endow the set $W_2^2(\mathbb{R}^d)$ with a metric by defining the 2-Wasserstein distance between $\mu$ and $\nu$ as $W_2^2(\mu, \nu) = T_2(\mu, \nu)^{1/2}$. More details on Wasserstein distances and their links with optimal transport problems can be found in Rachev (1984) or Villani (2009) for instance.

Here we will consider probabilities in $W_2^2(\mathbb{R})$. In this case, the Wasserstein distance can be written as

$W_2^2(\mu, \nu) = \int_0^1 (F^{-1}(t) - G^{-1}(t))^2 dt$, \hspace{1cm} (1)

where $F$ (resp. $G$) is the distribution function associated with $\mu$ (resp. $\nu$).

Moreover, we are dealing with more than two probabilities and so we are interested in a global measure of separation. So consider the Wasserstein 2-variation of $\nu_1, \ldots, \nu_J$, defined as follows. Given probabilities $\nu_1, \ldots, \nu_J$ on $\mathbb{R}^d$ with finite 2-th moment let

$V(\nu_1, \ldots, \nu_J) = \inf_{\eta \in W_2(\mathbb{R}^d)} \left( \frac{1}{J} \sum_{j=1}^J W_2^2(\nu_j, \eta) \right)^{1/2}$.
be the Wasserstein 2-variation of $\nu_1, \ldots, \nu_J$. In Agueh and Carlier (2011), the minimizer of $\eta \mapsto \frac{1}{J} \sum_{j=1}^{J} W_2^2(\nu_j, \eta)$ is proved to exist. This measure $\nu_B$ is called the barycenter or Fréchet mean of $\nu_1, \ldots, \nu_J$. The authors prove properties of existence and uniqueness for barycentres of measures in $W_2(\mathbb{R}^d)$, while the properties of the empirical version are provided in Boissard, Le Gouic and Loubes (2015).

We propose to use this Wasserstein 2-variation as a goodness of fit criterion for model $(H)$. Since the true distribution $\mu$ is unknown, we first try to invert the warping operator and thus compute for each observation its image through a candidate deformation $\varphi_j$,

$$Z_{i,j}(\varphi_j) = \varphi_j(X_{i,j}) \quad 1 \leq i \leq n, \quad 1 \leq j \leq J.$$ 

Note that $Z_{i,j}(\varphi_j) \sim \mu_{\varphi_j}$. Now, if we set $\varphi = (\varphi_1, \ldots, \varphi_J) \in \mathcal{G}$, then the Fréchet mean of $(\mu_{\varphi_j})_{1 \leq j \leq J}$ is the probability $\mu_B(\varphi)$ with quantile function

$$F_{B}^{-1}(\varphi)(t) = \frac{1}{J} \sum_{k=1}^{J} \varphi_k \circ F_{k}^{-1}(t),$$

(see Agueh and Carlier (2011)). We will write $\mu_{n,j}(\varphi_j)$ for the empirical measure on $Z_{i,j}(\varphi_j), 1 \leq i \leq n$ and $\mu_{n,B}(\varphi)$ for the corresponding Fréchet mean. It is important to remark that

under $(H)$ \quad $\mu_B(\varphi^*) = \mu = \mu_{\varphi_j}^*$, \quad $\forall 1 \leq j \leq J$.

Hence, a natural idea to test whether $(H)$ holds, is to consider the Wasserstein 2-variation of the $(\mu_{\varphi_j}), 1 \leq j \leq J$, that is to say the minimum alignment of the candidate warped distributions $(\mu_{\varphi_j})_{1 \leq j \leq J}$ with respect to their barycenter, namely $\mu_B(\varphi)$. This optimization program corresponds to the minimization in $\varphi \in \mathcal{G}$ of the following theoretical criterion

$$U(\varphi) := V^2(\mu_1(\varphi_1), \ldots, \mu_J(\varphi_J)) = \frac{1}{J} \sum_{j=1}^{J} W_2^2(\mu_{\varphi_j}, \mu_B(\varphi)).$$

Its empirical version is given by $U_n(\varphi) = \frac{1}{J} W_2^2(\mu_{n,j}(\varphi_j), \mu_{n,B}(\varphi))$. Inference about model $(H)$ can be based on the statistic $\inf_{\varphi \in \mathcal{G}} U_n(\varphi)$. In the next sections we analyse the behavior of this statistics under different setups.

3. Non parametric model for deformations

We provide in the section a CLT for $\inf_{\varphi \in \mathcal{G}} U_n(\varphi)$ under the following set of assumptions.

For all $j$, $F_j$ is $C^2$ on $(c_j; d_j)$, $f_j(x) > 0$ if $x \in (c_j; d_j)$ and 

$$(4.2)$$
are moment assumptions on the (possibly is satisfied by the Gaussian distribution to and Csörgő Rajput is related to the regularity of the deformation. The integrability condition \( L^p(\mathcal{X}) \) the norm \( \|h\|_{\mathcal{H}_j} = \sup_{(c_j,d_j)} \|h\|_{\mathcal{H}_j} + \mathbb{E}[\|h(X_j)\|_{L^p}] \), and on the product space \( \mathcal{H}_1 \times \cdots \times \mathcal{H}_J, \|h\|_{\mathcal{H}} = \sum_{j=1}^J \|h_j\|_{\mathcal{H}_j} \). The we make the following additional assumptions.

\[
\mathcal{G}_j \subset \mathcal{H}_j \text{ is compact for } \|\cdot\|_{\mathcal{H}_j} \text{ and } \sup_{h \in \mathcal{G}_j} |h'(x_n^j) - h'(x)| \to 0. \tag{4.4}
\]

for some \( r > 4 \) and \( 1 \leq j \leq J \), \( \mathbb{E}[|X_j|^r] < \infty \tag{4.5} \)

for some \( r > \max(4,p_0) \) and \( 1 \leq j \leq J \), \( \mathbb{E}\left[ \sup_{h \in \mathcal{G}_j} |h(X_j)|^r \right] < \infty \tag{4.6} \)

Under Assumptions \( A1 \) to \( A6 \), we are able to provide the asymptotic distribution of \( \inf_{\varphi \in \mathcal{G}} \sqrt{n}U_n(\varphi) \). It is convenient at this point to give some explanation about the meaning of these assumptions. \( A2 \) is a is a regularity condition on the distributions of the \( X_j \)'s (it holds, for instance, for Gaussian or Pareto distributions) required for strong approximation of the quantile process, see Csörgő (1983) for details. The integrability condition \( A3 \) is satisfied by the Gaussian distribution if \( q < 2 \), see, e.g., Rajput (1972). \( A4 \) is related to the regularity of the deformation functions. Finally, \( A5 \) and \( A6 \) are moment assumptions on the (possibly warped) observations.

**Theorem 3.1.** Under Assumptions \( A1 \) to \( A6 \)

\[
\sqrt{n} \left( \inf_{\varphi \in \mathcal{G}} U_n(\varphi) - \inf_{\varphi \in \mathcal{G}} U(\varphi) \right) \to \inf_{\varphi \in \Gamma} \frac{2}{\sqrt{n}} \sum_{j=1}^J \left( \int_0^1 \varphi_j' \circ F_j^{-1} \frac{B_j}{f_j \circ F_j}(\varphi_j \circ F_j^{-1} - F_B^{-1}(\varphi)) \right),
\]

where \( \Gamma = \{ \varphi \in \mathcal{G} : U(\varphi) = \inf_{\varphi \in \mathcal{G}} U(\phi) \} \) and \( (B_j)_{1 \leq j \leq J} \) are independent Brownian bridges.

A proof of Theorem 3.1 is given in the Appendix below. We note that continuity of \( U \) is follows easily from the choice of the norm on \( \mathcal{G} \). Recall that \( \mathcal{G} \) is compact and, consequently, \( \inf_{\varphi \in \mathcal{G}} U(\varphi) \) is attained. Hence, \( \Gamma \) is a nonempty closed subset of \( \mathcal{G} \) (in particular, it is also a compact set). We note further that the random variables \( \int_0^1 \varphi_j' \circ F_j^{-1} \frac{B_j}{f_j \circ F_j}(\varphi_j \circ F_j^{-1} - F_B^{-1}(\varphi)) \) are centered.
Gaussian, with covariance

\[
\int_{[0,1]^2} (\min(s,t) - st) \frac{\phi'(F^{-1}_j(t))}{f_j(F^{-1}_j(t))} (\varphi_j(F^{-1}_j(t)) - F_B^{-1}(\varphi)(t)) \times \frac{\phi'(F^{-1}_j(s))}{f_j(F^{-1}_j(s))} (\varphi_j(F^{-1}_j(s)) - F_B^{-1}(\varphi)(s)) ds dt.
\]

In particular, if \(U\) has a unique minimizer the limiting distribution in Theorem 3.1 is normal. However, our result works in more generality, even without uniqueness assumptions.

We remark also that although we have focused for simplicity on the case of samples of equal size, the case of different sample sizes, \(n_j, j = 1, \ldots, J\), can also be handled with straightforward changes. If we assume

\[
\forall j : n_j \to +\infty \quad \text{and} \quad \frac{n_j}{n_1 + \cdots + n_J} \to (\gamma_j)^2 > 0,
\]

then the result can be restated as

\[
\sqrt{n_1 \cdots n_J} \left( \inf_{\varphi} U_{n_1, \ldots, n_J} - \inf_{\varphi} U \right) \to \inf_{\varphi \in \Gamma} \frac{2}{J} \sum_{j=1}^J \tilde{S}_j,
\]

where \(U_{n_1, \ldots, n_J}\) denotes the empirical Wasserstein variation computed from the samples and \(\tilde{S}_j(\varphi) = (\Pi_{p \neq j} \gamma_p) \int_0^1 \phi' \circ F^{-1}_j \frac{B_j}{f_j \circ F_j} (\varphi_j \circ F^{-1}_j - F_B^{-1}(\varphi)).\)

As a final remark in this section we note that in the case where \(\mathcal{H}\) holds, we have \(\varphi_j \circ F^{-1}_j = F_B^{-1}(\varphi)\) for each \(\varphi \in \Gamma\). Thus, the result of Theorem 3.1 becomes

\[
\inf_{\varphi \in \mathcal{G}} \sqrt{n} U_n(\varphi) \to 0.
\]

Hence, in this case we have to refine our study to understand well the behavior of \(\inf_{\varphi} U_n\) when \(n\) tends to infinity. This is what we consider in the next section. In this case we restrict ourselves to a to a semiparametric warping model where \(\mu\) is unknown but where the deformations are indexed by a parametric family.

4. A parametric model for deformations

In many cases, deformation functions can be made more specific in the sense that they follow a known shape depending on parameters that are different for each sample. So consider the parametric model \(\theta^\ast = (\theta^\ast_1, \ldots, \theta^\ast_J)\) such that \(\varphi_j^\ast = \varphi_{\theta^\ast_j}, \quad \text{for all } j = 1, \ldots, J.\) Each \(\theta^\ast_j\) represents the warping effect that undergoes the \(j\)th sample, which must be removed to recover the unknown distribution by inverting the warping operator. So Assumption \(\mathcal{H}\) becomes

\[
X_{i,j} = \varphi_{\theta^\ast_j}^{-1}(\varepsilon_{i,j}), \quad \text{for all } 1 \leq i \leq n, 1 \leq j \leq J.
\]

Hence, from now on, we will consider the following family of deformations, indexed by a parameter \(\lambda \in \Lambda \subset \mathbb{R}^p:\)

\[
\varphi : \Lambda \times (c;d) \to (a,b) \\
(\lambda, x) \mapsto \varphi_{\lambda}(x)
\]
Thus, the functions $U$ and $U_n$ are now defined on $\Theta = \Lambda^J$, and the criterion of interest becomes $\inf_{\lambda \in \Theta} U(\lambda)$. We also use the simplified notation $\mu_j(\theta_j)$ instead of $\mu_j(\varphi_{\theta_j})$, $F_B(\theta)$ for $F_B(\varphi_{\theta_1}, \ldots, \varphi_{\theta_J})$ and similarly for the empirical versions. Throughout this section we assume that model $\mathcal{H}$ holds. This means, in particular, that the d.f.’s of the samples, $F_j$, satisfy $F_j = G \circ \varphi_{\theta_j}$, with $G$ the d.f. of the $\varepsilon_{ij}$’s.

For the analysis of this setup, we adapt Assumptions $\mathcal{A}_1$ to $\mathcal{A}_6$, replacing them by the following versions.

For all $\lambda \in \Lambda, \varphi_\lambda : (c; d) \rightarrow (a; b)$ is invertible, increasing, \hspace{1cm} (A1)

and s.t. $-\infty \leq a < b \leq +\infty, \hspace{0.5cm} -\infty \leq c \leq c_j < d_j \leq d \leq +\infty$.

We replace $\mathcal{A}_2$ by: $G$ is $C^2$ with $G'(x) = g(x) > 0$ on $(a, b)$ and

$$\sup_{a < x < b} \frac{G(x)(1 - G(x))g'(x)}{g(x)^2} < \infty$$ \hspace{1cm} (A2)

Now, instead of $\mathcal{A}_3$ to $\mathcal{A}_5$ we assume

$\varphi$ is continuous w.r.t. $x$ and $\lambda$ \hspace{1cm} (A3)

$\forall \lambda \in \Lambda, \varphi_\lambda$ is $C^1$ with respect to $x$, $\Lambda$ is compact

$d\varphi$ is bounded on $\Lambda \times [c_j; d_j]$ and continuous with respect to $\lambda$ \hspace{1cm} (A4)

and $\sup_{\lambda \in \Lambda, |x_n - x| \rightarrow 0} \left| \frac{d\varphi_\lambda(x_n) - d\varphi_\lambda(x)}{|x_n - x|} \right| \rightarrow 0$.

$\forall 1 \leq j \leq J \hspace{0.5cm} \mathbb{E} [|X_j|^r] < \infty$ for some $r > 4$ \hspace{1cm} (A5)

Here $d$ is the derivation operator w.r.t. $x$, while $\partial$ will be the derivation operator w.r.t. $\lambda$. Finally $\mathcal{A}_6$ becomes

$\forall 1 \leq j \leq J \hspace{0.5cm} \mathbb{E} \left[ \sup_{\lambda \in \Lambda} |\varphi_\lambda(X_j)|^r \right] < \infty$ for some $r > 4$ \hspace{1cm} (A6)

Note that Assumption $\mathcal{A}_6$ implies that $\varepsilon$ has a moment of order $r > 4$ and also that Assumption $\mathcal{A}_3$ becomes simpler in a parametric model which does not require a particular topology.

We impose as identifiability condition,

$U$ has a unique minimizer, $\theta^*$, that belongs to the interior of $\Lambda$. \hspace{1cm} (A7)

Note that, equivalently, this means that $\theta^*$ is the unique zero of $U$, since we are assuming that $\mathcal{H}$ holds.

Now, to get sharper result about the convergence of $\inf_{\theta \in \Theta} U_n(\theta)$, one has to add the following assumptions, first on the deformation functions.

$\forall 1 \leq j \leq J \hspace{0.5cm} \varphi_{\theta_j}^{-1}$ is $C^1$ w.r.t. $x$ and $d\varphi_{\theta_j}^{-1}$ is bounded on $[a, b]$ \hspace{1cm} (A8)

$\varphi$ is $C^2$ w.r.t. $x$ and $\lambda$
\[ \forall 1 \leq j \leq J \quad \mathbb{E} \left[ \sup_{\lambda \in \Lambda} \left| \partial^2 \varphi_{\lambda} \left( \varphi^{-1}_{\theta^*} (\varepsilon) \right) \right|^2 \right] < \infty \quad \text{(A9)} \]

As said for Assumption \( A_3 \), the following one is more restrictive on the tail of the distribution of \( \varepsilon \), excluding the Gaussian case. Examples of such variables with unbounded support are given in del Barrio, Deheuvels and van de Geer (2007) p.76. Note that distributions with compact support and strictly positive, continuous density satisfy this assumption.

\[ \int_0^1 \frac{t(1-t)}{g^2(G^{-1}(t))} \, dt < \infty \quad \text{(A10)} \]

**4.1. Estimation of the deformation model**

Set

\[ \hat{\theta}^n \in \arg \min_{\theta \in \Theta} U^n(\theta). \]

The results in this section are stated in the case where \( \Lambda \) is a subset of \( \mathbb{R} \). However they are still true if \( \Lambda \subset \mathbb{R}^p \) with corresponding changes. The following result implies that \( \hat{\theta}^n \) is a good candidate to estimate \( \theta^* \). It is a simple consequence of continuity of \( U \) plus uniform convergence in probability of \( U_n \) to \( U \), as shown in the proof of Theorem 3.1. We omit details.

**Proposition 4.1.** Under \( A_1 \) to \( A_7 \), then

\[ \hat{\theta}^n \to \theta^* \text{ in probability.} \]

We can refine this result by making the following additional assumption,

\[ R_j := \partial \varphi_{\theta^*} \circ \varphi^{-1}_{\theta^*} \] is continuous and bounded on \([a, b], 1 \leq j \leq J\). \( \text{(TCL)} \)

Define now \( \Phi = [\Phi_{i,j}]_{1 \leq i,j \leq J} \) with

\[ \Phi_{i,j} = -\frac{2}{J^2} \langle R_i, R_j \rangle_{\mu}, \quad \Phi_{i,i} = \frac{2(J-1)}{J^2} \| R_i \|_{\mu}, \quad \text{(3)} \]

where \( \| \cdot \|_{\mu} \) and \( \langle \cdot, \cdot \rangle_{\mu} \) denote norm and inner product, respectively, in \( L^2(\mu) \). \( \Phi \) is a symmetric, positive semidefinite matrix. To see this, consider \( x \in \mathbb{R}^J \) and note that

\[ x' \Phi x = \frac{2}{J^2} \int \left( \sum_i (J-1)x_i^2 R_i^2 - 2 \sum_{i<j} x_ix_j R_i R_j \right) d\mu \]
\[ = \frac{2}{J^2} \int \sum_{i<j} (x_i R_i - x_j R_j)^2 d\mu \geq 0. \]

In fact, \( \Phi \) is positive definite, hence invertible, unless all the \( R_i \) are proportional \( \mu \)-a.s.. Now, we have the following Central limit Theorem, which is proved in the Appendix.
Proposition 4.2. Under Assumptions A1 to A9 and TCL, if, in addition, $\Phi$ is invertible, then

$$\sqrt{n}(\hat{\theta}^n - \theta^*) \to \Phi^{-1}Y,$$

where $Y \overset{d}{=} (Y_1, \ldots, Y_J)$ with

$$Y_j = \frac{2}{J} \int_0^1 R_j \circ G^{-1} \frac{\tilde{B}_j}{g \circ G^{-1}},$$

$\tilde{B}_j = B_j - \frac{1}{J} \sum_{k=1}^J B_k$ and $(B_j)_{1 \leq j \leq J}$ independent Brownian bridges.

We note that, while, for simplicity, we have formulated Proposition 4.1 assuming that the deformation model holds, a similar version can be proved (with some additional assumptions and changes in $\Phi$) in the case when the model is false and $\theta^*$ is not the true parameter, but the one that gives the best (but imperfect) alignment.

Remark 1. The identifiability condition A7 can be too strong to be realistic. Actually, for some deformation models it could happen that $\varphi_0 \circ \varphi_\eta = \varphi_{\theta \ast \eta}$ for some $\theta \ast \eta \in \Theta$. In this case, if $X_{i,j} = \varphi_{\theta \ast \eta}^{-1}(\varepsilon_{i,j})$ with $\varepsilon_{i,j}$ i.i.d., then, for any $\theta$, $X_{i,j} = \varphi_{\theta \ast \eta}^{-1}(\delta_{i,j})$ which are also i.i.d. and, consequently, $(\theta \ast \theta_1^*, \ldots, \theta \ast \theta_J^*)$ is also a zero of $U$. This applies, for instance, to location and scale models. A simple fix to this issue is to select one of the signals as the reference, say the $J$-th signal, and assume that $\theta_J^*$ is known (since it can be, in fact, chosen arbitrarily). The criterion function becomes then $\hat{U}(\theta_1, \ldots, \theta_{J-1}) = U(\theta_1, \ldots, \theta_{J-1}, \theta_J^*)$. One could then make the (more realistic) assumption that $\theta^* = (\theta_1^*, \ldots, \theta_{J-1}^*)$ is the unique zero of $\hat{U}$ and base the analysis on $\hat{U}_n(\theta_1, \ldots, \theta_{J-1}) = U_n(\theta_1, \ldots, \theta_{J-1}, \theta_J^*)$ and $\hat{\theta}^n = \arg \min_{\hat{\theta}} \hat{U}_n(\hat{\theta})$.

The results in this section can be adapted almost verbatim to this setup. Proposition 4.2 holds, namely, $\sqrt{n}(\hat{\theta}^n - \theta^*) \to \Phi^{-1}Y$, with $Y \overset{d}{=} (Y_1, \ldots, Y_{J-1})$ and $\Phi = [\Phi_{i,j}]_{1 \leq i,j \leq J-1}$. We note further that invertibility of $\Phi$ is almost granted. In fact, arguing as above, we see that

$$x'\Phi x = \frac{2}{J^2} \int \left( \sum_{1 \leq i < j \leq J-1} (x_i R_i - x_j R_j)^2 + \sum_{1 \leq j \leq J-1} x_j^2 R_j^2 \right) d\mu \geq 0$$

and $\Phi$ is positive definite unless $R_i = 0$ $\mu$-c.s. for $i = 1, \ldots, J - 1$.

4.2. Asymptotic behavior of Wasserstein’s variation under the null

Here we are able to specify the speed of convergence of $\inf_{\theta \in \Theta} U_n(\theta)$ to zero when $H$ holds, providing the asymptotic distribution of this statistic.

Theorem 4.3. Under assumptions A1 to A10, TCL and invertibility of $\Phi$,

$$n \inf_{\hat{\theta} \in \Theta} U_n(\hat{\theta}) \to - \frac{1}{J} \sum_{j=1}^J \int_0^1 \left( \frac{\tilde{B}_j}{g \circ G^{-1}} \right)^2 - \frac{1}{2} Y' \Phi^{-1} Y$$

9
with \( Y = (Y_1, \ldots, Y_J) \), \( Y_j = \frac{2}{\gamma} \int_0^1 R_j \circ G^{-1} \frac{\hat{G}_j}{\gamma} \), \( \tilde{B} = B_j - \frac{1}{J} \sum_{k=1}^J B_k \) and \((B_j)_{1 \leq j \leq J}\) independent Brownian bridges.

A proof of Theorem 4.3 is given in the Appendix. As for Theorem 3.1, this result can be generalized to the case of different sample sizes with straightforward changes. We also note that the result can also be adapted to the setup of Remark 1, replacing the correction term \( \frac{1}{2} Y' \Phi^{-1} Y \) by \( \frac{1}{2} \tilde{Y}' \tilde{\Phi}^{-1} \tilde{Y} \).

Turning back to our goal of assessment of the deformation model \( \mathcal{H} \) based on the observed value of \( \inf_{\theta \in \Theta} U_n(\theta) \), Theorem 4.3 gives some insight into the threshold levels for rejection of \( \mathcal{H} \). However, the limiting distribution still depends on unknown objects and designing a tractable test requires to estimate the quantiles of this distribution. This will be achieved in the next section.

5. Testing procedure with Wasserstein distance

5.1. Bootstrap with Wasserstein distance

In this section we present general results on Wasserstein distances that we will apply to estimate the asymptotic distribution of a statistic test based on an alignment with respect to the Wasserstein’s barycenter. More precisely, here we consider distributions on \( \mathbb{R}^d \) with a moment of order \( r \geq 1 \), that is, distributions in \( \mathcal{W}_r(\mathbb{R}^d) \). \( W_r \) will denote Wasserstein distance with \( L_r \) cost, namely,

\[
W_r(\nu, \eta) = \inf_{\pi \in \Pi(\nu, \eta)} \int \|y - z\|^r d\pi(y, z),
\]

where \( \| \cdot \| \) is any norm on \( \mathbb{R}^d \). Finally, we write \( \mathcal{L}(Z) \) for the law of any random variable \( Z \). We note the abuse of notation in the following, in which \( W_r \) is used both for Wasserstein distance on \( \mathbb{R} \) and on \( \mathbb{R}^d \), but this should not cause much confusion.

The next result shows that the laws of empirical transportation costs are continuous (and even Lipschitz) functions of the underlying distributions.

**Proposition 5.1.** Set \( \nu, \nu', \eta \) probability measures in \( \mathcal{W}_r(\mathbb{R}^d) \), \( Y_1, \ldots, Y_n \) i.i.d. random vectors with common law \( \nu \), \( Y'_1, \ldots, Y'_n \) i.i.d. with law \( \nu' \) and write \( \nu_n, \nu'_n \) for the corresponding empirical measures. Then

\[
W_r(\mathcal{L}(W_r(\nu_n, \eta)), \mathcal{L}(W_r(\nu'_n, \eta))) \leq W_r(\nu, \nu').
\]

Our deformation assessment criterion concerns a particular version of the Wasserstein \( r \)-variation of distributions \( \nu_1, \ldots, \nu_J \) in \( \mathcal{W}_r(\mathbb{R}^d) \), that we will denote in its general form by

\[
V_r(\nu_1, \ldots, \nu_J) := \inf_{\eta \in \mathcal{W}_r(\mathbb{R}^d)} \left( \frac{1}{J} \sum_{j=1}^J W_r(\nu_j, \eta) \right)^{1/r}.
\]

\( V_r \) is just the average distance to the \( r \)-barycenter of the set.
It is convenient to note that $V_r^*(\nu_1, \ldots, \nu_J)$ can also be expressed as

$$V_r^*(\nu_1, \ldots, \nu_J) = \inf_{\pi \in \Pi(\nu_1, \ldots, \nu_J)} \int T(y_1, \ldots, y_J) d\pi(y_1, \ldots, y_J), \quad (4)$$

where $\Pi(\nu_1, \ldots, \nu_J)$ denotes the set of probability measures on $\mathbb{R}^d$ with marginals $\nu_1, \ldots, \nu_J$ and $T(y_1, \ldots, y_J) = \min_{z \in \mathbb{R}^d} \frac{1}{r} \sum_{j=1}^J \|y_j - z\|^r$. A discussion about this formulation for $r = 2$ and a result on existence and uniqueness of a minimizer in problem (4) are given in Proposition 4.2 in Agueh and Carlier (2011).

Here we are interested in empirical Wasserstein $r$-variations, namely, the $r$-variations computed from the empirical measures $\nu_{n,j}$ coming from independent samples $Y_1, \ldots, Y_{n,j}$ of i.i.d. random variables with distribution $\nu_j$. Note that in this case problem (4) is a linear optimisation problem for which a minimizer always exists.

As before, we consider the continuity of the law of empirical Wasserstein $r$-variations with respect to the underlying probabilities. This is covered in the next result.

**Proposition 5.2.** With the above notation

$$W_r^*(\mathcal{L}(V_r(\nu_{n,1}, \ldots, \nu_{n,J}))), \mathcal{L}(V_r(\nu'_{n,1}, \ldots, \nu'_{n,J}))) \leq \frac{1}{J} \sum_{j=1}^J W_r^*(\nu_j, \nu'_j).$$

A useful consequence of the above results is that empirical Wasserstein distances or $r$-variations can be bootstrapped under rather general conditions. To be more precise, we take in Proposition 5.1 $\nu' = \nu_n$, the empirical measure on $Y_1, \ldots, Y_n$, and consider a bootstrap sample $Y_1^*, \ldots, Y_n^*$ of i.i.d. (conditionally given $Y_1, \ldots, Y_n$) observations with common law $\nu_n$. We write $\nu_m^*$ for the empirical measure on $Y_1^*, \ldots, Y_n^*$ and $\mathcal{L}^*(Z)$ for the conditional law of $Z$ given $Y_1, \ldots, Y_n$. Proposition 5.1 now reads

$$W_r^*(\mathcal{L}^*(W_r(\nu_m^*, \nu)), \mathcal{L}(W_r(\nu_m^*, \nu))) \leq W_r(\nu_n, \nu).$$

Hence, if $W_r(\nu_n, \nu) = O_p(1/r_n)$ for some sequence $r_n > 0$ such that $r_m/r_n \to 0$ as $n \to \infty$, then, using that $W_r(\mathcal{L}(aX), \mathcal{L}(aY)) = aW_r(\mathcal{L}(X), \mathcal{L}(Y))$ for $a > 0$, we see that

$$W_r^*(\mathcal{L}^*(r_m W_r(\nu_m^*, \nu)), \mathcal{L}(r_m W_r(\nu_m^*, \nu))) \leq \frac{r_m}{r_n} r_n W_r(\nu_n, \nu) \to 0 \quad (5)$$

in probability.

If in addition $r_n W_r(\nu_n, \nu) \to \gamma(\nu)$ for a distribution $\gamma(\nu)$ then

$$r_m W_r(\nu_m^*, \nu) \to \gamma(\nu)$$

which entails that if $\hat{c}_n(\alpha)$ denotes the $\alpha$ quantile of the conditional law $\mathcal{L}^*(r_m W_r(\nu_m^*, \nu))$ then under some regularity conditions on the distribution $\gamma(\nu)$

$$\mathbb{P}(r_n W_r(\nu_n, \nu) \leq \hat{c}_n(\alpha)) \to \alpha \quad \text{as } n \to \infty. \quad (6)$$
We conclude in this case that the quantiles of $r_n W_r (\nu_n, \nu)$ can be consistently estimated by the bootstrap quantiles, that is, the conditional quantiles of $r_m W_r (\nu_{m_n}^*, \nu)$ (which, in turn, can be approximated through Monte-Carlo simulation).

As an example, if $d = 1$ and $r = 2$, under integrability and smoothness assumptions on $\nu$ we have
\[\sqrt{n} W_2 (\nu_n, \nu) \to \left( \int_0^1 \frac{B^2(t)}{f^2(F^{-1}(t))} \, dt \right)^{1/2},\]
where $f$ and $F^{-1}$ are the density and the quantile function of $\nu$.

### 5.2. Bootstrap for Wasserstein’s barycenter alignment

In the non parametric deformation model, statistical inference is based on the minimal Wasserstein variation
\[v_n^2 := \inf_{\phi \in \Phi} V_2^2 (\mu_1, \ldots, \mu_n, \theta) = \inf_{\phi \in \Phi} U_n,\]
where $\mu_{n,j} (\theta)$ denotes the empirical measure on $Z_{1,j} (\theta), \ldots, Z_{n,j} (\theta)$, where $Z_{i,j} (\theta) = \varphi_j^{-1} (X_{1, j})$ and $X_{1,j}, \ldots, X_{n,j}$ are independent i.i.d. samples from $\mu_j$. Consider $v_n^2$, the corresponding version obtained from samples with underlying distributions $\mu_j^*$, and denote by $\mathcal{L} (v_n)$ (resp. $\mathcal{L} (v_n^*)$) the law of the random variable $v_n$ (resp. $v_n^*$).

Then, the following result holds, setting $\| \varphi_j \|_\infty = \sup_{x \in (c_j, d_j)} |\varphi_j (x)|$.

**Theorem 5.3.** Under Assumption A1, if for all $j$ $\mathcal{G}_j \subset C^1 (c_j, d_j)$ and $\sup_{\varphi \in \Phi} \| \varphi_j \|_\infty < \infty$, then
\[W_2^2 (\mathcal{L} (v_n), \mathcal{L} (v_n^*)) \leq \sup_{\varphi \in \Phi} \| \varphi_j \|_\infty^2 \frac{1}{j} \sum_{j=1}^j W_2^2 (\mu_j, \mu_j^*).\]

Now consider bootstrap samples $X_{1,j}^*, \ldots, X_{m_n,j}^*$ of i.i.d. observations sampled from $\mu_{n,j}$, write $\mu_{n,j}^*$ for the empirical measure on $X_{1,j}^*, \ldots, X_{m_n,j}^*$ (conditionally to the $X_{1,j}, \ldots, X_{n,j}$) and denote $V_2^2 (\mu_{n,j}^*, \theta_1, \ldots, \mu_{n,j}^*, \theta_j) = U_{m_n}^* (\theta)$. Then we get

**Corollary 5.4.** If $m_n \to \infty$, and $m_n / \sqrt{n} \to 0$, then under Assumptions A1 to A6, and if $\inf_{\mathcal{G}} U > 0$, writing $\gamma$ for the limit distribution in Theorem 3.1, we have that
\[\mathcal{L}^* \left( \sqrt{m_n} \left( \inf_{\mu} U_{m_n}^* - \inf_{\mu} U \right) \right) \to \gamma\]
in probability. In particular, if $\hat{c}_n (\alpha)$ denotes the conditional (given the $X_{1,j}$’s) $\alpha$-quantile of $\sqrt{m_n} \left( \inf_{\mu} U_{m_n}^* - \inf_{\mu} U \right)$ then
\[\mathbb{P} \left( \sqrt{m_n} \left( \inf_{\mu} U_{m_n}^* - \inf_{\mu} U \right) \leq \hat{c}_n (\alpha) \right) \to \alpha. \quad (7)\]

Now consider the parametric deformation model and note that the inference about it is based on the minimal Wasserstein variation
\[v_n^2 := \inf_{\theta \in \Theta} V_2^2 (\mu_{n,1} (\theta), \ldots, \mu_{n,j} (\theta)) = \inf_{\theta} U_n,\]
where \( \mu_{n,j}(\theta) \) denotes the empirical measure on \( Z_{1,j}(\theta), \ldots, Z_{n,j}(\theta) \), \( Z_{i,j}(\theta) = \varphi_{ij}^{-1}(X_{1,j}) \) and \( X_{1,j}, \ldots, X_{n,j} \) are independent i.i.d. samples from \( \mu_j \). We consider \( v'_n \), the corresponding version obtained from \( v_n \) (resp. \( v'_n \)) the law of the random variable \( v_n \) (resp. \( v'_n \)).

Then, we are able to prove the following result.

**Theorem 5.5.** Under Assumptions A1, A3 and A4

\[
W^2(L(v_n), L(v'_n)) \leq \sup_{x \in (c,d), \lambda \in \Lambda} |d\varphi_\lambda(x)|^2 \frac{1}{J} \sum_{j=1}^J W^2(\mu_j, \mu'_j).
\]

Now consider bootstrap samples \( X^*_1, \ldots, X^*_m,j \) of i.i.d. observations sampled from \( \mu^*_j \), write \( \mu^*_{n,j} \) for the empirical measure on \( X^*_1, \ldots, X^*_m,j \) (conditionally to the \( X_{1,j}, \ldots, X_{n,j} \)) and denote \( V^2(\mu^*_{n,1}(\theta), \ldots, \mu^*_{n,J}(\theta)) = U^*_{m,n}(\theta) \).

**Corollary 5.6.** If \( m_n \to \infty \), and \( m_n/n \to 0 \), then under Assumptions A1 to A10, TCL and writing \( \gamma(G; \theta^*) \) for the limit distribution in Theorem 4.3, we have that

\[
\mathcal{L}^* \left( \inf_{\theta \in \Theta} U^*_{m,n} \right) \Rightarrow \gamma(G; \theta^*)
\]

in probability. In particular, if \( \hat{c}_n(\alpha) \) denotes the conditional (given the \( X_{i,j} \)'s) \( \alpha \)-quantile of \( \inf_{\theta \in \Theta} U^*_{m,n} \) then if the quantile function of \( \gamma(G; \theta^*) \) is continuous w.r.t \( \alpha \)

\[
P \left( \inf_{\theta \in \Theta} U^* \leq \hat{c}_n(\alpha) \right) \to \alpha.
\]  

(8)

### 5.3. Goodness of fit

In the semi parametric model, we can now provide a goodness of fit procedure. Under Assumptions of Theorem 4.3 (A1 to A10 and TCL) one can test the null assumption

\[
\inf_{\theta \in \Theta} U(\theta) = 0 \quad (H_0)
\]

versus its complementary denoted by \( H_1 \).

In this case the test statistic is \( n \inf_{\Theta} U_n \) and one can get the asymptotic level of a reject region of the form \( \{ n \inf_{\Theta} U_n > \lambda_n \} \) by using Corollary 5.6.

More precisely, consider bootstrap samples \( X^*_1, \ldots, X^*_m,j \) of i.i.d. observations sampled from \( \mu_{n,j} \), and write \( U^*_{m,n}(\theta) \) for the corresponding criterion. Then, if \( \hat{c}_n(\alpha) \) denotes the conditional (given the \( X_{i,j} \)'s) \( (1 - \alpha) \)-quantile of \( m_n \inf_{\Theta} U^*_{m,n} \)

\[
P \left( \inf_{\theta \in \Theta} U_n(\theta) > \hat{c}_n(\alpha) \right) \to \alpha.
\]

Thus \( \{ n \inf_{\Theta \in \Theta} U_n(\theta) > \hat{c}_n(\alpha) \} \) will be a reject region of asymptotic level \( \alpha \), and \( \hat{c}_n(\alpha) \) can be computed using a Monte-Carlo method.
Note that in the case of a non parametric model, a test can be designed
switching the null hypothesis. Hence set for \( \Delta_0 > 0 \) set
\[
\inf_{\Theta} U = \Delta_0 \tag{\mathcal{H}_0^1}
\]
\[
\inf_{\Theta} U < \Delta_0 \tag{\mathcal{H}_1^1}
\]
The test statistic in this case is \( U_n (\Delta_0) := \sqrt{n} (\inf_{\Theta} U_n - \Delta_0). \) Then, under
assumptions of Corollary 5.4 (A1 to A6), if \( \hat{c}_n (\alpha) \) denotes the conditional (given
the \( X_{i,j} \)'s) \( \alpha \)-quantile of the bootstrap version \( \sqrt{m_n} (\inf_{\Theta} U_{m,n} - \Delta_0), \) under \( \mathcal{H}_0^1 \)
\[
P (U_n (\Delta_0) \leq \hat{c}_n (\alpha)) \to \alpha,
\]
which gives the asymptotic level of the reject region \( \{ U_n (\Delta_0) \leq \hat{c}_n (\alpha) \} \), where
\( \hat{c}_n (\alpha) \) can be computed using a Monte-Carlo method.

This procedure can be made more precise under Assumptions of Theorem
3.1 in the parametric case (A1 to A6). Set for \( 1 \leq j \leq J, \) set \( S_j (\theta) = \int_0^1 \phi_j \frac{B_j (t)}{f_j^{-1} (t)} \left( \frac{F_j (t)}{f_j (t)} - F_j^{-1} (\theta) (t) \right) dt, \) independent centered
Gaussian variables. Then the result of Theorem 3.1 can be restated as
\[
\sqrt{n} \left\{ \inf_{\Theta} U_n - \inf_{\Theta} U \right\} \to \frac{2}{J} \sum_{j=1}^J S_j (\theta^*) .
\]
Let \( \sigma_j^2 \) the variance of \( S_j (\theta^*). \) Set \( \hat{L}_j \left( \frac{1}{n} \right) = \frac{1}{n} \left\{ \bar{Z}_{(1),j} \left( \hat{\theta}^n \right)^2 - \bar{Z}_{(1),j} \left( \hat{\theta}^n \right)^2 \right\} - \sum_{k=2}^i \left\{ 1 \right\} \sum_{p=1}^J \bar{Z}_{(k),p} \left( \hat{\theta}^n \right) \right\} \left( \bar{Z}_{(k),j} \left( \hat{\theta}^n \right) - \bar{Z}_{(k-1),j} \left( \hat{\theta}^n \right) \right) \]
Then we could prove that
\[
\hat{\sigma}_n^2 = \frac{n}{n-1} \sum_{i=2}^n \hat{L}_j \left( \frac{i}{n} \right) - \frac{1}{n^2} \sum_{k,j=2}^{n} \hat{L}_j \left( \frac{i}{n} \right) \hat{L}_j \left( \frac{k}{n} \right)
\]
converges in probability to \( \sigma_j^2. \) Hence, we can now provide a test procedure for
the null assumption
\[
\inf_{\Theta} U \geq \Delta_0 \tag{\mathcal{H}_0^2}
\]
versus its complementary denoted by \( \mathcal{H}_1^2. \)

Here we set the test statistic as \( V_n (\Delta_0) := \sqrt{n} \inf_{\Theta} U_n - \Delta_0. \) Then
\[
V_n (\Delta_0) = \sqrt{n} \inf_{\Theta} U_n - \inf_{\Theta} U + \sqrt{n} \inf_{\Theta} U - \Delta_0
\]
and if \( \inf_{\Theta} U = \Delta_0 \)
\[
V_n (\Delta_0) \to Z \sim N (0, 1)
\]
else, if \( \inf_{\Theta} U > \Delta_0, \) we get that for all \( m \in \mathbb{R} \)
\[
P (V_n (\Delta_0) \geq m) \to 1.
\]
Then,
\[ \sup_{(\mu_1, \ldots, \mu_J)} \lim_{n \to \infty} \mathbb{P}(\mathcal{V}_n(\Delta_0) \leq \lambda) \leq \Phi(\lambda) \]

where \( \Phi \) is the distribution function of the standard normal distribution. Thus we can construct a test of asymptotic level \( \alpha \) by choosing the reject region \( \{ \mathcal{V}_n(\Delta_0) \leq \Phi^{-1}(\alpha) \} \).

6. Appendix

We provide here proofs of the main results in this paper. For those in Sections 3 and 4 our approach relies on the consideration of quantile processes, namely,

\[ \rho_{n,j}(t) = \sqrt{n} f_j(F_j^{-1}(t))(F_{n,j}^{-1}(t) - F_j^{-1}(t)), \quad 0 < j < 1, \quad j = 1, \ldots, J, \]

and on strong approximations of quantile processes, as in the following result that we adapt from Csörgő and Horváth (1993) (Theorem 2.1, p. 381 there).

**Theorem 6.1.** Under \( \mathcal{A}_2 \), there exist, on a rich enough probability space, independent versions of \( \rho_{n,j} \) and independent families of Brownian bridges \( \{B_{n,j}\}_{n=1}^{\infty}, \quad j = 1, \ldots, J \) satisfying

\[ n^{1/2 - \nu} \sup_{1/n \leq t \leq 1/n} \frac{|\rho_{n,j}(t) - B_{n,j}(t)|}{(t(1-t))^{3/4}} = \begin{cases} O_p(\log(n)) & \text{if } \nu = 0 \\ O_p(1) & \text{if } 0 < \nu \leq 1/2 \end{cases} \]

We will make frequent use in this section of the following technical Lemma which generalizes a result in Álvarez-Esteban et al. (2008).

**Lemma 6.2.** Under Assumption \( \mathcal{A}_6 \)

i) \( \sup_{h \in \mathcal{G}_j} \sqrt{n} \int_0^1 h(F_j^{-1}(t))^2 dt \to 0, \quad \sup_{h \in \mathcal{G}_j} \sqrt{n} \int_{1-1/n}^{1/2} (h(F_j^{-1}(t)))^2 dt \to 0 \)

ii) \( \sup_{h \in \mathcal{G}_j} \sqrt{n} \int_0^{1/2} (h(F_{n,j}^{-1}(t)))^2 dt \to 0, \quad \sup_{h \in \mathcal{G}_j} \sqrt{n} \int_{1-1/n}^{1/2} (h(F_{n,j}^{-1}(t)))^2 dt \to 0 \) in probability.

iii) If moreover \( \mathcal{A}_3 \) holds

\[ \forall k, j \int_0^1 \frac{\sqrt{t(1-t)}}{f_k(F_k^{-1}(t))} \sup_{\varphi \in \mathcal{G}} \left| \varphi_j(F_j^{-1}(t)) - F_B^{-1}(\varphi)(t) \right| dt < \infty \quad (9) \]

iv) In the parametric case, under Assumptions \( \mathcal{A}_3, \mathcal{A}_6 \) and if \( \forall k, F_k \) is \( C^1 \) with \( F_k' = f_k > 0 \) on \( (c_k, d_k) \)

\[ \forall k, j \int_0^1 \frac{\sqrt{t(1-t)}}{f_k(F_k^{-1}(t))} \sup_{\theta \in \Theta} \left| \varphi_j^{-1}(F_j^{-1}(t)) - F_B^{-1}(\theta)(t) \right| dt < \infty \quad (10) \]

Our next proof is inspired by Álvarez-Esteban et al. (2008). The main part concerns the study of \( \sqrt{n} \mathcal{U}_n(\varphi) \) uniformly in \( \varphi \) in probability by using strong approximations of the quantile process with Brownian bridges.
Proof of Theorem 3.1. We will work with the versions of $\rho_{n,j}$ and $B_{n,j}$ given by Theorem 6.1. We show first that

$$\sup_{\varphi \in \mathcal{G}} \left| \sqrt{n} \left( U_n(\varphi) - U(\varphi) \right) - \frac{1}{J} \sum_{j=1}^{J} S_{n,j}(\varphi) \right| \to 0 \text{ in probability} \quad (11)$$

with $S_{n,j}(\varphi) = 2 \int_0^1 \varphi_j' \circ F_{n,j}^{-1}(\varphi_j \circ F_{j}^{-1} - F_B^{-1}(\varphi)) \frac{B_{n,j}}{f_j \circ f_j'}$. To check this we note that the fact that $\frac{1}{J} \sum_{j=1}^{J} \varphi_j \circ F_{j}^{-1} = F_B^{-1}(\varphi)$ and simple algebra yield

$$\sqrt{n}(U_n(\varphi) - U(\varphi)) = \frac{2}{J} \sum_{j=1}^{J} \tilde{S}_{n,j} + \frac{1}{J} \sum_{j=1}^{J} \tilde{R}_{n,j}$$

with

$$\tilde{S}_{n,j} = \sqrt{n} \int_0^1 (\varphi_j \circ F_{n,j}^{-1} - \varphi_j \circ F_{j}^{-1})(\varphi_j \circ F_{j}^{-1} - F_B^{-1}(\varphi)),$$

$$\tilde{R}_{n,j} = \sqrt{n} \int_0^1 [(\varphi_j \circ F_{n,j}^{-1} - \varphi_j \circ F_{j}^{-1}) - (F_{n,B}(\varphi) - F_B^{-1}(\varphi))]^2.$$

From the elementary inequality $(a_1 + \cdots + a_J)^2 \leq J a_1^2 + \cdots + J a_J^2$ we get that

$$\frac{1}{J} \sum_{j=1}^{J} \tilde{R}_{n,j} \leq \frac{4}{J} \sqrt{n} \sum_{j=1}^{J} \int_0^1 (\varphi_j \circ F_{n,j}^{-1} - \varphi_j \circ F_{j}^{-1})^2$$

Now, for every $t \in (0, 1)$ we have

$$\varphi_j \circ F_{n,j}^{-1}(t) - \varphi_j \circ F_{j}^{-1}(t) = \varphi_j' (K_{n,j}(t))(F_{n,j}^{-1}(t) - F_{j}^{-1}(t)) \quad (12)$$

for some $K_{n,j}(t)$ between $F_{n,j}^{-1}(t)$ and $F_{j}^{-1}(t)$. Assumption $A4$ implies $C_j := \sup_{\varphi_j \in \mathcal{G}_j, \varphi_j(x) \in (c_j, d_j)} |\varphi_j'(x)| < \infty$. Hence, we have

$$\int_0^1 (\varphi_j \circ F_{n,j}^{-1} - \varphi_j \circ F_{j}^{-1})^2 \leq C_j^2 \int_0^1 (F_{n,j}^{-1} - F_{j}^{-1})^2.$$

Now we can use $A5$ and argue as in the proof of Theorem 2 in Álvarez-Esteban et al. (2008) to conclude that $\sqrt{n} \int_0^1 (F_{n,j}^{-1} - F_{j}^{-1})^2 \to 0$ in probability and, as a consequence, that

$$\sup_{\varphi \in \mathcal{G}} \left| \sqrt{n} \left( U_n(\varphi) - U(\varphi) \right) - \frac{1}{J} \sum_{j=1}^{J} \tilde{S}_{n,j}(\varphi) \right| \to 0 \text{ in probability}. \quad (13)$$

On the other hand, the Cauchy-Schwarz's inequality shows that

$$n \left( \int_0^1 (\varphi_j \circ F_{n,j}^{-1} - \varphi_j \circ F_{j}^{-1})(\varphi_j \circ F_{j}^{-1} - F_B^{-1}(\varphi)) \right)^2 \leq \sqrt{n} \int_0^1 (\varphi_j \circ F_{n,j}^{-1} - \varphi_j \circ F_{j}^{-1})^2 \sqrt{n} \int_0^1 (\varphi_j \circ F_{j}^{-1} - F_B^{-1}(\varphi))^2$$

16
and using i) and ii) of Lemma 6.2, the two factors converge to zero uniformly in \( \varphi \). A similar argument works for the upper tail and allows to conclude that we can replace in (13) \( \tilde{S}_{n,j}(\varphi) \) with \( \tilde{S}_{n,j}(\varphi) := 2\sqrt{n} \int_0^{1/2} (\varphi_j \circ F_n^{-1} - \varphi_j \circ F_j^{-1})(\varphi_j \circ F_j^{-1} - F_B^{-1}(\varphi)) \). Moreover,

\[
\sup_{\varphi \in \mathcal{G}} \left| \int_0^{1/2} \frac{B_{n,j}}{f_j \circ F_j} \varphi_j \circ F_j^{-1} (\varphi_j \circ F_j^{-1} - F_B^{-1}(\varphi)) \right| \leq C_j \int_0^{1/2} \sup_{\varphi \in \mathcal{G}} \left| (\varphi_j \circ F_j^{-1} - F_B^{-1}(\varphi)) \right|
\]

and by iii) of Lemma 6.2 and Cauchy-Schwarz’s inequality

\[
\mathbb{E} \left[ \int_0^{1/2} \left| \frac{B_{n,j}}{f_j \circ F_j} \sup_{\varphi \in \mathcal{G}} \left| (\varphi_j \circ F_j^{-1} - F_B^{-1}(\varphi)) \right| \right| \right] \leq \int_0^{1/2} \sqrt{I(t)} \sup_{\varphi \in \mathcal{G}} \left| \varphi_j(F_j^{-1}(t)) - F_B^{-1}(\varphi)(t) \right| dt \to 0.
\]

Hence, \( \sup_{\varphi \in \mathcal{G}} \left| \int_0^{1/2} \frac{B_{n,j}}{f_j \circ F_j} (\varphi_j \circ F_j^{-1} - F_B^{-1}(\varphi)) \right| \to 0 \) in probability and similarly for the right tail. Thus (recall (12)), to prove (11) it suffices to show that

\[
\sup_{\varphi \in \mathcal{G}} \left| \int_{1/2}^{1} \frac{B_{n,j}(t)}{f_j(F_j^{-1}(t))} (\varphi_j(F_j^{-1}(t)) - F_B^{-1}(\varphi)(t)) dt \right| \to 0
\]

in probability. To check it we take \( \nu \in (0,1/2) \) and use Theorem 6.1 to get

\[
\int_{1/2}^{1} \frac{|p_{n,j}(t) - B_{n,j}(t)|}{f_j(F_j^{-1}(t))} \sup_{\varphi \in \mathcal{G}} \left| \varphi_j(F_j^{-1}(t)) - F_B^{-1}(\varphi)(t) \right| dt \\
\leq \nu^{1/2} O_P(1) \int_{1/2}^{1} \frac{(t(t - 1))^{1/2}}{f_k(F_k^{-1}(t))} \sup_{\varphi \in \mathcal{G}} \left| \varphi_j(F_j^{-1}(t)) - F_B^{-1}(\varphi)(t) \right| dt \to 0
\]

in probability (using dominated convergence and iii) of Lemma 6.2).

We observe next that, for all \( t \in (0,1) \), \( \sup_{\varphi \in \mathcal{G}} |K_n,\varphi_j(t) - F_j^{-1}(t)| \) \( \to 0 \) almost surely, since \( K_n,\varphi_j(t) \) lies between \( F_n^{-1}(t) \) and \( F_j^{-1}(t) \). Therefore, using Assumption .44 we see that \( \sup_{\varphi \in \mathcal{G}} |\varphi_j'(K_n,\varphi_j(t)) - F_j^{-1}(t)| \) \( \to 0 \) almost surely while, on the other hand \( \sup_{\varphi \in \mathcal{G}} |\varphi_j'(K_n,\varphi_j(t)) - F_j^{-1}(t)| \leq 2C_j \).

But then, by dominated convergence we get that

\[
\mathbb{E} \left[ \sup_{\varphi \in \mathcal{G}} |\varphi_j'(K_n,\varphi_j(t)) - F_j^{-1}(t)|^2 \right] \to 0.
\]
Since by iii) of Lemma 6.2 we have that \( t \to \sqrt{(1-t)} f_j(F_j^{-1}(t)) \) is integrable we conclude that

\[
\mathbb{E} \sup_{\varphi \in \mathcal{G}} \int_{\frac{1}{n}}^{\frac{1}{n-\frac{1}{2}}} |\varphi'_j(K_{n,\varphi_j}(t)) - \varphi'_j(F_j^{-1}(t))| \left| \frac{B_{n,j}(t)}{f_j(F_j^{-1}(t))} \right| \varphi_j(F_j^{-1}(t)) - F_B^{-1}(\varphi)(t) \] \[dt\]

tends to 0 as \( n \to \infty \) and, consequently,

\[
\sup_{\varphi \in \mathcal{G}} \int_{\frac{1}{n}}^{\frac{1}{n-\frac{1}{2}}} |\varphi'_j(K_{n,\varphi_j}(t)) - \varphi'_j(F_j^{-1}(t))| \left| \frac{B_{n,j}(t)}{f_j(F_j^{-1}(t))} \right| \varphi_j(F_j^{-1}(t)) - F_B^{-1}(\varphi)(t) \] \[dt\]

vanishes in probability. Combining this fact with (15) we prove (14) and, as a consequence, (11).

Observe now that for all \( n \in \mathbb{N} \), \( (S_{n,j}(\varphi))_{1 \leq j \leq J} \) has the same law as \( (S_j(\varphi))_{1 \leq j \leq J} \) with

\[
S_j(\varphi) = 2 \int_0^1 \varphi'_j \circ F_j^{-1}(\varphi_j \circ F_j^{-1} - F_B^{-1}(\varphi)) \frac{B_j}{f_j \circ F_j^{-1}}
\]

and \( (B_j)_{1 \leq j \leq J} \) independent standard Brownian bridges. Set \( S = \frac{1}{J} \sum_{j=1}^J S_j \). Now, (11) implies that

\[
\sqrt{n} (U^n(\cdot) - U(\cdot)) \rightarrow S(\cdot)
\]

in the space \( L^\infty(\mathcal{G}) \) (we denote by \( \| \cdot \|_\infty \) the norm on this space). From Skorohod Theorem we know that there exists some probability space on which the convergence (16) holds almost surely. From now on, we place us on this space. Then, for \( \varphi, \rho \in \mathcal{G} \)

\[
|S_j(\varphi) - S_j(\rho)| \leq 2 \sup_{(c_j,d_j)} |\varphi'_j - \rho'_j| \int_0^1 \left| \frac{B_j}{f_j \circ F_j^{-1}}(\varphi_j \circ F_j^{-1} - F_B^{-1}(\varphi)) \right| \]
\[
+ 2 \left| \int_0^1 \frac{B_j}{f_j \circ F_j^{-1}} \rho'_j \circ F_j^{-1}(\varphi_j \circ F_j^{-1} - \rho_j \circ F_j^{-1}) \right|
\]
\[
\leq 2 \sup_{(c_j,d_j)} |\varphi'_j - \rho'_j| \sup_{\varphi \in \mathcal{G}} \left| \int_0^1 \frac{B_j}{f_j \circ F_j^{-1}}(\varphi_j \circ F_j^{-1} - F_B^{-1}(\varphi)) \right| \]
\[
+ 2 \sup_{(c_j,d_j)} |\rho'_j| \left( \int_0^1 \left| \frac{B_j}{f_j \circ F_j^{-1}} \right|^q \right)^{1/q} \left( \int_0^1 |\varphi_j \circ F_j^{-1} - \rho_j \circ F_j^{-1}|^{p_0} \right)^{1/p_0}
\]

But using iii) of Lemma 6.2

\[
\mathbb{E} \left[ \sup_{\varphi \in \mathcal{G}} \left| \int_0^1 \frac{B_j}{f_j \circ F_j^{-1}}(\varphi_j \circ F_j^{-1} - F_B^{-1}(\varphi)) \right| \right]
\]
\[
\leq \int_0^1 \sqrt{(1-t)} \sup_{\varphi \in \mathcal{G}} |\varphi_j(F_j^{-1}(t)) - F_B^{-1}(\varphi)(t)| \] \[dt < \infty
\]
Hence, almost surely, \( \sup_{\varphi \in G} \left| \int_0^1 \frac{B_j}{f_j \circ F_j} (\varphi_j \circ F_j^{-1} - F_j^{-1}(\varphi)) \right| < \infty \). Furthermore, from Assumption \( \mathcal{A}3 \), we get that a.s.

\[
\int_0^1 \left( \frac{B_j}{f_j \circ F_j} \right)^q < \infty
\]

and thus, for some random variable \( T \) a.s. finite, and \( \varphi, \rho \in G \), we get

\[ |S_j(\varphi) - S_j(\rho)| \leq T \| \varphi - \rho \|_G. \]

Thus, we deduce that \((S_j)_{1 \leq j \leq J}\) are almost surely continuous functions on \( G \), endowed with the norm \( \| \cdot \|_G \).

Observe now that

\[
\sqrt{n} \left( \inf_{\varphi} U_n - \inf_{\varphi} U \right) \leq \sqrt{n} \inf_{\Gamma} U_n - \sqrt{n} \inf_{\Gamma} U = \inf_{\Gamma} \sqrt{n} (U_n - U). \quad (17)
\]

On the other hand, if we consider the (a.s.) compact set \( \Gamma_n = \{ \varphi \in G : U(\varphi) \leq \inf_G U + \frac{2}{\sqrt{n}} \| \sqrt{n} (U_n - U) \|_{\infty} \} \), then, if \( \varphi \notin \Gamma_n \),

\[
U_n(\varphi) \geq \inf_{\varphi} U + 2 \| (U_n - U) \|_{\infty} - \| (U_n - U) \|_{\infty},
\]

which implies

\[
U_n(\varphi) \geq \inf_{\varphi} U + \| (U_n - U) \|_{\infty},
\]

while if \( \varphi \in \Gamma \), then,

\[
U_n(\varphi) = \inf_{\varphi} U + U^n(\varphi) - U^n(\varphi) < \inf_{\varphi} U + \| (U_n - U) \|_{\infty}.
\]

Thus, necessarily, \( \inf_{\varphi} U_n = \inf_{\Gamma_n} U_n = \inf_{\Gamma_n} (U_n - U) \geq \inf_{\Gamma_n} (U_n - U) + \inf_{\Gamma_n} U = \inf_{\Gamma_n} (U_n - U) + \inf_{\Gamma_n} U \). Together with (17) this entails

\[
\inf_{\Gamma_n} \sqrt{n} (U_n - U) \leq \sqrt{n} \left( \inf_{\varphi} U_n - \inf_{\varphi} U \right) \leq \inf_{\Gamma} \sqrt{n} (U_n - U). \quad (18)
\]

Note that for the versions that we are considering \( \| \sqrt{n} (U_n - U) - S \|_{\infty} \to 0 \) a.s.. In particular, this implies that \( \inf_{\Gamma} \sqrt{n} (U_n - U) \to \inf_{\Gamma} S \) a.s.. Hence, the proof will be complete if we show that a.s.

\[
\inf_{\Gamma_n} \sqrt{n} (U_n - U) \to \inf_{\Gamma} S. \quad (19)
\]

To check this last point, consider a sequence \( \varphi_n \in \Gamma_n \) such that \( \sqrt{n} (U_n(\varphi_n) - U(\varphi_n)) \leq \inf_{\Gamma_n} \sqrt{n} (U_n - U) + \frac{1}{n} \). By compactness of \( G \), taking subsequences if necessary, \( \varphi_n \to \varphi_0 \) for some \( \varphi_0 \). Continuity of \( U \) yields \( U(\varphi_n) \to U(\varphi_0) \) and as a consequence, that \( U(\varphi_0) \leq \inf_{\varphi} U \), that is, \( \varphi_0 \in \Gamma \) a.s.. Furthermore,

\[
\left| \sqrt{n} (U_n - U)(\varphi_n) - S(\varphi_0) \right| \leq \left| \sqrt{n} (U_n - U) - S \right|_{\infty} + \left| S(\varphi_n) - S(\varphi_0) \right| \to 0.
\]

19
This shows that
\[
\liminf_{1} \sqrt{n} (U_n - U) \geq S(\varphi_0) \geq \inf_{1} S
\]  
and yields (19). This completes the proof. 

\[\Box\]

**Proof of Proposition 4.2**. We denote by \( \partial_j \) the derivative operator w.r.t. \( \theta_j \), \( 1 \leq j \leq J \) and \( \partial_{j,k} \) for second order partial derivatives. We note that \( H \) entails that the empirical d.f. on the \( j \)-th sample, \( F_{n,j}(t) \), satisfies \( F_{n,j}(t) = G_{n,j}(\varphi_{\theta_j}^j(t)) \) with \( G_{n,j} \) the empirical d.f. on the \( \varepsilon_{i,j} \)'s (which are i.i.d. \( \mu \), with d.f. \( G \)). We write now \( \rho_{n,j} \) for the quantile process based on the \( \varepsilon_{i,j} \)'s. We write \( B_{n,j} \) for independent Brownian bridges as given by Theorem (A2) grants the existence of such \( B_{n,j} \)'s.

Assumption TCL implies that \( \partial \varphi_{\theta_j}^j \in L^2(X_j) \). Moreover, with Assumptions A8, A9 and compactness of \( \Theta \), we deduce that \( \sup_{\lambda \in \Lambda} \partial \varphi_\lambda \in L^2(X_j) \). On the other hand, since \( \varepsilon \) has a moment of order \( r > 4 \), arguing as in the proof of point 3 in Lemma 6.2 we have that
\[
\int_0^1 \frac{\sqrt{t(1-t)}}{g(G^{-1}(t))} dt < \infty.  
\]  
From A8 and A9 we have that \( U_n \) is a \( C^2 \) function and derivatives can be computed by differentiation under the integral sign. This implies that
\[
\partial_j U_n(\theta) = \frac{2}{J} \int_0^1 \partial \varphi_{\theta_j}(F_{n,j}^{-1}(t))(\varphi_{\theta_j}(F_{n,j}^{-1}(t)) - \frac{1}{J} \sum_{k=1}^J \varphi_{\theta_k}(F_{n,k}^{-1}(t))) dt, 
\]
\[
\partial_{p,q}^2 U_n(\theta) = -\frac{2}{J^2} \int_0^1 \partial \varphi_{\theta_p}(F_{n,p}^{-1}(t)) \partial \varphi_{\theta_q}(F_{n,q}^{-1}(t)) dt, \quad p \neq q
\]
and
\[
\partial_{p,p}^2 U_n(\theta) = \frac{2}{J} \int_0^1 \partial^2 \varphi_{\theta_p}((F_{n,p})^{-1}(t))(\varphi_{\theta_p}(F_{n,p}^{-1}(t)) - \frac{1}{J} \sum_{k=1}^J \varphi_{\theta_k}(F_{n,k}^{-1}(t))) 
\]
\[
\quad + \frac{2(J-1)}{J^2} \int_0^1 (\partial \varphi_{\theta_p}(F_{n,p}^{-1}(t))^2 dt. 
\]
Similar expressions are obtained for the derivatives of \( U(\theta) \) (replacing everywhere \( F_{n,j} \) with \( F_j^{-1} = \varphi_{\theta_j}^{-1} \circ G^{-1} \)). We write \( DU_n(\theta) = (\partial_j U_n(\theta))_{1 \leq j \leq J} \), \( DU(\theta) = (\partial_j U(\theta))_{1 \leq j \leq J} \) for the gradients and \( \Phi_n(\theta) = [\partial_{p,q}^2 U_n(\theta)]_{1 \leq p,q \leq J} \), \( \Phi(\theta) = [\partial_{p,q}^2 U(\theta)]_{1 \leq p,q \leq J} \) for the Hessians of \( U_n \) and \( U \). Note that \( \Phi^* = \Phi(\theta^*) \) is assumed to be invertible.

Recalling that \( R_j = \partial \varphi_{\theta_j} \circ \varphi_{\theta_j}^{-1} \), from the fact \( DU(\theta^*) = 0 \) we see that
\[
\sqrt{n} \partial_j U_n(\theta^*) = \frac{2}{J} \int_0^1 R_j(G_{n,j}^{-1}(t)) \frac{\rho_{n,j}(t) - \frac{1}{J} \sum_{k=1}^J \rho_{n,k}(t)}{g(G^{-1}(t))} dt. 
\]
Now, using Assumption \textbf{TCL} and arguing as in the proof of Theorem 3.1 we conclude that
\[\left| \int_0^1 R_j(G_n^{-1}(t)) \frac{\rho_{n,k}(t)}{g(G^{-1}(t))} dt - \int_0^1 R_j(G^{-1}(t)) \frac{B_{n,k}(t)}{g(G^{-1}(t))} dt \right| \to 0\]
in probability and, consequently,
\[\left| \sqrt{n} \partial_j U_n(\theta^*) - \frac{2}{J} \int_0^1 R_j(G^{-1}(t)) \frac{B_{n,j}(t)}{g(G^{-1}(t))} dt \right| \to 0 \quad (24)\]
in probability.
A Taylor expansion of \(\partial_j U_n\) around \(\theta^*\) shows that for some \(\hat{\theta}_j^n\) between \(\hat{\theta}_j^n\) and \(\theta^*\) we have
\[\partial_j U_n(\hat{\theta}_j^n) = \partial_j U_n(\theta^*) + (\partial^2_{j,j} U_n(\hat{\theta}_j^n), \ldots, \partial^2_{J,j} U_n(\hat{\theta}_j^n)) \cdot (\hat{\theta}_j^n - \theta^*)\]
and because \(\hat{\theta}_j^n\) is a zero of \(DU_n\), we obtain
\[-\partial_j U_n(\theta^*) = (\partial^2_{j,j} U_n(\hat{\theta}_j^n), \ldots, \partial^2_{J,j} U_n(\hat{\theta}_j^n)) \cdot (\hat{\theta}_j^n - \theta^*).\]
Writing \(\hat{\Phi}_n\) for the \((J-1) \times (J-1)\) matrix whose \(J-1\)-th row equals \((\partial^2_{j,j} U_n(\hat{\theta}_j^n), \ldots, \partial^2_{J,j} U_n(\hat{\theta}_j^n)), j = 2, \ldots, J,\) we can rewrite the last expansion as
\[-\sqrt{n} DU_n(\theta^*) = \hat{\Phi}_n \sqrt{n}(\hat{\theta}_j^n - \theta^*). \quad (25)\]

We show next that \(\hat{\Phi}_n \to \Phi^* = \Phi(\theta^*)\) in probability. Recalling (22), we consider first \(\int_0^1 (\partial \varphi_{\hat{\theta}_p}^n(F_n^{-1}(t)))^2 dt\). We have
\[
\left( \int_0^1 (\partial \varphi_{\hat{\theta}_p}^n(F_n^{-1}(t)))^2 dt \right)^{1/2} \leq \left( \int_0^1 (\partial \varphi_{\hat{\theta}_p}^n(F_n^{-1}(t)) - \partial \varphi_{\theta^*}(F_n^{-1}(t)))^2 dt \right)^{1/2} + \left( \int_0^1 (\varphi_{\hat{\theta}_p}^n(F_n^{-1}(t)) - \varphi_{\theta^*}(F_n^{-1}(t)))^2 dt \right)^{1/2} \leq \left( \int_0^1 \sup_{\lambda \in \Lambda} |\partial^2 \varphi_{\lambda}(F_n^{-1})(t)|^2 dt \right)^{1/2} |\hat{\theta}_p^n - \theta^*| + \left( \int_0^1 \left( R_p(G_n^{-1}(t)) - R_p(G^{-1}(t))^2 dt \right) \right)^{1/2} \to 0\]
in probability, where we have used assumptions \textbf{A9}, \textbf{TCL} and Proposition 4.1. A similar argument shows that \(\int_0^1 (\varphi_{\hat{\theta}_p}^n(F_n^{-1}(t)) - \varphi_{\theta^*}(F_n^{-1}(t)))^2 dt\) in probability. As a consequence, we conclude
\[\hat{\Phi}_n \to \Phi^*, \quad \text{in probability.} \quad (26)\]
Now, (25), (24) (26) together with Slutsky's Theorem complete the proof.

□

**Proof of Theorem 4.3.** We consider the same notation and setup as in the proof of Proposition 4.2. Since $DU_n(\hat{\theta}^n) = 0$, a Taylor expansion around $\hat{\theta}^n$ shows that

$$nU_n(\theta^*) - nU_n(\hat{\theta}^n) = \frac{1}{2}(\sqrt{n}(\hat{\theta}^n - \theta^*))' \Phi(\hat{\theta}^n)(\sqrt{n}(\hat{\theta}^n - \theta^*))$$

(27)

for some $\tilde{\theta}_n$ between $\hat{\theta}^n$ and $\theta^*$. Arguing as in the proof of Proposition 4.2 we see that $\Phi(\tilde{\theta}_n) \to \Phi^*$ in probability. Hence, to complete the proof it suffices to show that

$$nU_n(\theta^*) - \frac{1}{J} \sum_{j=1}^{k} \int_{0}^{1} \frac{(B_{n,j}(t) - \frac{1}{J} \sum_{k=1}^{J} B_{n,k}(t))^2}{g(G^{-1}(t))^2} dt \to 0$$

in probability. Since

$$nU_n(\theta^*) = \frac{1}{J} \sum_{j=1}^{k} \int_{0}^{1} \frac{\left(\rho_{n,j}(t) - \frac{1}{J} \sum_{k=1}^{J} \rho_{n,k}(t)\right)^2}{g(G^{-1}(t))^2} dt,$$

this amounts to proving that

$$\int_{0}^{1} \frac{\left(\rho_{n,j}(t) - B_{n,j}(t)\right)^2}{g(G^{-1}(t))^2} dt \to 0$$

in probability.

Taking $\nu \in (0, \frac{1}{2})$ in Theorem 6.1 we see that

$$\int_{\frac{1}{n}}^{1-\frac{1}{n}} \frac{\left(\rho_{n,j}(t) - B_{n,j}(t)\right)^2}{g(G^{-1}(t))^2} dt \leq O_P(1) \frac{1}{n^{1-2\nu}} \int_{\frac{1}{n}}^{1-\frac{1}{n}} \frac{(t(1-t))^{2\nu}}{g(G^{-1}(t))^2} dt \to 0,$$

using condition (A10) and dominated convergence. From (A10) we also see that $\int_{\frac{1}{n}}^{1-\frac{1}{n}} \frac{B_{n,j}(t)^2}{g(G^{-1}(t))^2} dt \to 0$ in probability. Condition (A10) implies also that $\int_{\frac{1}{n}}^{1-\frac{1}{n}} \frac{\rho_{n,j}(t)^2}{g(G^{-1}(t))^2} dt \to 0$ in probability, see Samworth and Johnson (2004). Similar considerations apply to the left tail and complete the proof.

□

**Proof of Proposition 5.1.** We set $T_n = W_r(\nu_n, \eta)$ and $T_n' = W_r(\nu'_n, \eta)$ and $\Pi_n(\eta)$ for the set of probabilities on $\{1, \ldots, n\} \times \mathbb{R}^d$ with first marginal equal to the discrete uniform distribution on $\{1, \ldots, n\}$ and second marginal equal to $\eta$ and note that we have $T_n = \inf_{\pi \in \Pi_n(\eta)} a(\pi)$ if we denote

$$a(\pi) = \left(\int_{\{1, \ldots, n\} \times \mathbb{R}^d} ||Y_i - z||^r d\pi(i, z)\right)^{1/r}.$$
We define similarly $a'(\pi)$ from the $Y'_i$ sample to get $T'_n = \inf_{x \in \Pi_n(\eta_n)} a'(\pi)$. But then, using the inequality $||a - b|| \leq ||a - b||$, 

$$|a(\pi) - a'(\pi)| \leq \left( \int_{\{1, \ldots, n\} \times \mathbb{R}^d} |Y_i - Y'_i|^r d\pi(i, z) \right)^{1/r} = \left( \frac{1}{n} \sum_{i=1}^n |Y_i - Y'_i|^r \right)^{1/r}$$

This implies that 

$$|T_n - T'_n|^r \leq \frac{1}{n} \sum_{i=1}^n |Y_i - Y'_i|^r.$$

If we take now $(Y, Y')$ to be an optimal coupling of $\nu$ and $\nu'$, so that $E[|Y - Y'|^r] = W_r(\nu, \nu')$ and $(Y_1, Y'_1, \ldots, Y_n, Y'_n)$ to be i.i.d. copies of $(Y, Y')$ we see that for the corresponding realizations of $T_n$ and $T'_n$ we have 

$$\mathbb{E}[|T_n - T'_n|^r] \leq \frac{1}{n} \sum_{i=1}^n \mathbb{E}[|Y_i - Y'_i|^r] = W_r(\nu, \nu').$$

But this shows that $W_r(L(T_n), L(T'_n)) \leq W_r(\nu, \nu')$, as claimed. 

\[\square\]

**Proof of Proposition 5.2.** We write $V_{r,n} = V_r(\nu_{n_1,1}, \ldots, \nu_{n_j,j})$ and $V'_{r,n} = V_r(\nu'_{n_1,1}, \ldots, \nu'_{n_j,j})$. We note that 

$$V'_{r,n} = \inf_{\pi \in \Pi_n(i_1, \ldots, i_j)} \int T(i_1, \ldots, i_j) d\pi(i_1, \ldots, i_j),$$

where $U_j$ is the discrete uniform distribution on $\{1, \ldots, n_j\}$ and 

$$T(i_1, \ldots, i_j) = \min_{z \in \mathbb{R}^d} \frac{1}{j} \sum_{j=1}^j |Y_{i_j,j} - z|^r. \text{ We write } T'(i_1, \ldots, i_j) \text{ for the equivalent function computed from the } Y'_{i,j}\text{'s. Hence we have}$$

$$|T(i_1, \ldots, i_j)^{1/r} - T'(i_1, \ldots, i_j)^{1/r}|^r \leq \frac{1}{j} \sum_{j=1}^j |Y_{i_j,j} - Y'_{i_j,j}|^r,$$

which implies 

$$\left( \int T(i_1, \ldots, i_j) d\pi(i_1, \ldots, i_j) \right)^{1/r} - \left( \int T(i_1, \ldots, i_j) d\pi(i_1, \ldots, i_j) \right)^{1/r} \right) |^r \leq \frac{1}{j} \sum_{j=1}^j |Y_{i_j,j} - Y'_{i_j,j}|^r d\pi(i_1, \ldots, i_j)$$

$$= \frac{1}{j} \sum_{j=1}^j |Y_{i_j,j} - Y'_{i_j,j}|^r \frac{1}{n} \sum_{i=1}^n Y_{i,j} - Y'_{i,j}|^r \right)$$

So, 

$$|V_{r,n} - V'_{r,n}|^r \leq \frac{1}{j} \sum_{j=1}^j \left( \frac{1}{n_j} \sum_{i=1}^{n_j} |Y_{i,j} - Y'_{i,j}|^r \right).$$
If we take \((Y_j, Y'_j)\) to be an optimal coupling of \(\nu_j\) and \(\nu'_j\) and \((Y_{n,j}, Y'_{n,j})\) to be i.i.d. copies of \((Y_j, Y'_j)\), for \(j = 1, \ldots, J\), then we obtain

\[
\mathbb{E} [ |V_{r,n} - V'_{r,n}|^r ] \leq \frac{1}{J} \sum_{j=1}^{J} \left( \frac{1}{n_j} \sum_{i=1}^{n_j} \mathbb{E} [ ||Y_{i,j} - Y'_{i,j}||^r ] \right) = \frac{1}{J} \sum_{j=1}^{J} W^r_r(\nu_j, \nu'_j).
\]

The conclusion follows.

\[ \square \]

**Proof of Theorem 5.3.** We can mimic the argument in the proof of Proposition 5.2 to get an upper bound on the Wasserstein distance between the laws of \(v_n\) and \(v'_n\), the corresponding version obtained from samples with underlying distributions \(\mu_j\). In fact, arguing as above, we can write

\[
v_n^2 = \inf_{\varphi \in \mathcal{G}} \left[ \inf_{\pi \in \Pi(U_{i,1}, \ldots, U_{i,J})} \int T(\varphi; i_1, \ldots, i_J) d\pi(i_1, \ldots, i_J) \right],
\]

where \(T(\varphi; i_1, \ldots, i_J) = \min_{y \in \mathbb{R}} \frac{1}{J} \sum_{j=1}^{J} (Z_{i,j}(\varphi) - y)^2\). We write \(T'(\varphi; i_1, \ldots, i_J)\) for the same function computed on the \(Z_{i,j}'(\varphi)\)'s and set

\[
||\varphi'||_\infty := \sup_{x \in (v,d)} |\varphi'_j(x)|.
\]

Now, from the fact \((Z_{i,j} - Z_{i,j}')^2 \leq ||\varphi'||^2_\infty (X_{i,j} - X_{i,j}')^2\) we see that

\[
|T(\varphi; i_1, \ldots, i_J)|^{1/2} - T'(\varphi; i_1, \ldots, i_J)|^{1/2} | \leq ||\varphi'||^2_\infty \frac{1}{J} \sum_{j=1}^{J} (X_{i,j} - X_{i,j}')^2
\]

and, as a consequence, that

\[
|V_2(\mu^n_j(\varphi), \ldots, \mu^n_j(\varphi)) - V_2(\mu'^n_j(\varphi), \ldots, \mu'^n_j(\varphi))|^2 \leq \frac{1}{J} \sum_{j=1}^{J} \sum_{i,j=1}^{n_j} \frac{1}{n_j} ||\varphi'||^2_\infty (X_{i,j} - X_{i,j}')^2
\]

and then

\[
(v_n - v'_n)^2 \leq ||\varphi'||^2_\infty \frac{1}{J} \sum_{j=1}^{J} \left( \frac{1}{n_j} \sum_{i,j=1}^{n_j} (X_{i,j} - X_{i,j}')^2 \right).
\]

If, as in the proof of Proposition 5.2, we assume that \((X_{i,j}, X'_{i,j})\), \(i = 1, \ldots, n_j\) are i.i.d. copies of an optimal coupling for \(\mu_j\) and \(\mu'_j\), with different samples independent from each other we obtain that

\[
\mathbb{E} [ (v_n - v'_n)^2 ] \leq ||\varphi'||^2_\infty \frac{1}{J} \sum_{j=1}^{J} W^2_2(\mu_j, \mu'_j).
\]
Proof of Corollary 5.4. In Theorem 5.3, take \( \mu'_j = \mu_{n,j} \), and set \( v_{mn}^* := \inf_{\varphi \in \mathcal{V}} V_2(\mu_{mn,1}^*(\varphi), \ldots, \mu_{mn,J}^*(\varphi)) \). Then, conditionally to the \( X_{1,j}, \ldots, X_{n,j} \), the result of Theorem 5.3 reads now
\[
W_2^2(\mathcal{L}(v_{mn}), \mathcal{L}(v_{mn}^*)) \leq \sup_{\varphi \in \mathcal{V}} \|\varphi'_j\|_\infty^2 \frac{1}{J} \sum_{j=1}^J W_2^2(\mu_j, \mu_{n,j}).
\]

Now, let \( v^2 := \inf_{\varphi \in \mathcal{V}} M(\varphi) \). Then,
\[
W_2^2(\mathcal{L}(v_{mn}), \mathcal{L}(v_{mn}^*)) = W_2^2(\mathcal{L}(v_{mn} - v), \mathcal{L}(v_{mn}^* - v)) \leq \sup_{\varphi \in \mathcal{V}} \|\varphi'_j\|_\infty^2 \frac{1}{J} \sum_{j=1}^J W_2^2(\mu_j, \mu_{n,j}).
\]

Now, recall that in the proof of Theorem 3.1 one gets that \( W_2^2(\mu_j, \mu_{n,j}) = O_p\left(\frac{1}{\sqrt{n}}\right) \). Then, using that \( W_r(\mathcal{L}(aX), \mathcal{L}(aY)) = aW_r(\mathcal{L}(X), \mathcal{L}(Y)) \) for \( a > 0 \), (28) gives
\[
W_2^2\left(\mathcal{L}\left(\sqrt{\frac{m}{n}}(v_{mn}^* - v)\right), \mathcal{L}\left(\sqrt{\frac{m}{n}}(v_{mn}^* - v)\right)\right) \leq \frac{m}{\sqrt{n}} \sup_{\varphi \in \mathcal{V}} \|\varphi'_j\|_\infty^2 \frac{1}{J} \sum_{j=1}^J nW_2^2(\mu_j, \mu_{n,j}) \to 0
\]

Moreover, under Assumptions \( A1 \) to \( A6 \), Theorem 3.1 gives \( \sqrt{\frac{m}{n}}(v_{mn}^* - v) \rightharpoonup \gamma \). If \( v > 0 \), the classical Delta Method (see for instance in Van der Vaart (2000) p.25) gives
\[
\sqrt{\frac{m}{n}}(v_{mn}^* - v) \rightharpoonup \frac{1}{2v}\gamma.
\]

Hence (29) enables to say that
\[
\sqrt{\frac{m}{n}}(v_{mn}^* - v) \rightharpoonup \frac{1}{2v}\gamma.
\]

Applying again a Delta Method leads to
\[
\sqrt{\frac{m}{n}}((v^*)^2_{mn} - v^2) = \sqrt{\frac{m}{n}}\left(\inf_{\mathcal{V}} U_{mn}^* - \inf_{\mathcal{V}} U\right) \rightharpoonup \gamma.
\]

(7) is obtained by using Glivenko Cantelli Theorem and convergence of the empirical quantiles.
