Introduction

Neospora caninum is now accounted as a major cause of abortion and congenital diseases in the dairy animal industry worldwide. The infection can pass via placenta causing serious economic losses among dairy and beef cattle due to a decrease in milk and meat production. In the Neospora life cycle, dogs play roles as definitive hosts and cattle and a wide range of domestic and wild animals including water buffalo (Bubalus bubalis) act as intermediate hosts. Water buffalo is naturally susceptible to Neospora caninum and can be experimentally infected with the parasite. Due to the economical importance of water buffaloes in the livestock industry, different surveys have been performed to study the seroprevalence of N. caninum in these merit animals around the world. The N. caninum infection is regularly diagnosed by serological tests performed on the blood samples like indirect fluorescent antibody test, agglutination test and enzyme-linked immunosorbent assay (ELISA). Due to the difficulties associated with a clinical diagnosis of neosporosis, serological tests are necessary for Neospora detection. These tests propose information about the seroprevalence of the parasite in herds, regions and countries. On the other hand, the interaction of the parasite with the immune system, the stages of parasitemia and the correlation between parasitemia and antibody production in water buffalo or even other intermediate hosts are still unclear. The northwest region of Iran is one of the most important places of buffalo breeding in Iran and buffalo breeding plays an important role in the regional economy.

The main objective of this study was to determine the prevalence rate of Neospora infection among buffaloes in a survey study and illustrate the concurrence between the presences of anti-N. caninum antibodies and Neospora DNA in the serum of these animals using a new developed whole tachyzoite-based ELISA and polymerase chain reaction (PCR) techniques.

Materials and Methods

Samples. Blood samples were collected from 83 water buffaloes (32 males and 51 females) in Urmia abattoir in the northwest of Iran. The samples were centrifuged at 1600 g for 10 min and sera were collected and stored at −20 °C until used.

Parasites. The N. caninum tachyzoites were obtained from Razi Vaccine and Serum Research Institute, Shiraz, Iran. The parasites were washed twice in phosphate-buffered saline (PBS) and reproduced in Vero cell line (Razi Vaccine and Serum Research Institute, Shiraz, Iran) cultured in Dulbecco's modified Eagle medium (Bio-Idea, Tehran, Iran) containing 10.00% fetal bovine serum (BIO-IDEA, Tehran, Iran) and 100 mg mL⁻¹ gentamicin (Sigma-Aldrich, Stelnhelm, Germany).

ELISA. Tachyzoites were washed twice with PBS and counted by Neubauer chamber, then ELISA plates (Biofil, Indore, India) were coated with 2 × 10^6 tachyzoites suspended in 1 mL PBS per well and incubated at 25 °C for three days. The plates were then washed three times with a washing buffer (PBS and 0.05% Tween 20 (Merck, Darmstadt, Germany) and then blocked with a blocking buffer (PBS and marvel milk 5.00%) at 37 °C for 1 hr. A number of serum samples collected from Neospora positive cows was used as positive controls and the blocking buffer was used as a negative control. The serum samples (positive controls or buffaloes samples) were first diluted in the blocking buffer (1:100) and put onto the plates in duplicate followed by incubation at 37 °C for 1 hr. After three times washing, horseradish peroxidase-conjugated sheep anti-bovine immunoglobulin G (IgG)-heavy chain antibody (Bethyl Laboratories, Montgomery, USA) was diluted in PBS (1:1000) containing 5.00% marvel milk and added to the plates incubating at 37 °C for 1 hr. After washing three times with the blocking buffer and two times with distilled water, a substrate including 3,3',5,5'-tetramethylbenzidine (Sigma-Aldrich), 10 µg mL⁻¹ dimethyl sulfoxide (Merck), 0.10% sodium acetate (Merck) and 10% hydrogen peroxide (Merck) was added and the plates were incubated at room temperature for 40 min. To stop the reaction, 2M H₂SO₄ (Merck) was used and the plate was then read at 450 nm on a micro-plate ELISA reader (ELX808, Bio Tec, Winooski, USA). The ratio of sample/positive control (S/P) optical densities (ODs) was calculated according to the following equation:

\[
S/P = \frac{Sample - NC}{PC - NC}
\]

where, NC was negative control and PC was positive control.

PCR. Samples with the S/P ratio of 0.50 or above were accounted as positive for N. caninum infection. Buffalo serum samples were analyzed for N. caninum NC5 gene using Np6 forward (5’-CTGCCAGTCAACTGCTTT CCT>3’) and Np21 reverse (5’-CCCAGTGCTCACATGCTGAACACACAG>3’) primers. The PCR was programmed with ASTEC pc708 thermal cycler (ASTEC, Chattanooga, USA) as 10 min at 95 °C for primary denaturation and 35 cycles of 95 °C for 1 min, 65 °C for 1 min and 72 °C for 2 min for denaturation, annealing and extension respectively and a final extension at 72 °C for 10 min. To confirm the presence of N. caninum NC5 gene, 1.00 µL of the PCR products were subjected to nested PCR using 5’-GTGTTGCTCTGCTGACGTGTTGCTGT-3’ forward and 5’-TACCAACTCCCTCGGTTCAC-3’ reverse primers. After 10 min primary denaturation at 95 °C, 35 cycles of PCR were run with 1 min denaturation at 95 °C, 45 sec annealing at 54 °C and 1 min extension at 72 °C. Finally, the reaction was completed with 10 min final extension at 72 °C. The ELISA results were statistically analyzed using Excel (version 15.0; Microsoft Corporation, Redmond, USA) and SPSS (version
Results

A method of ELISA based by using the whole *Neospora* cell as an antigen was set up to detect the level of anti-*N. caninum* IgG in the serum. The ratio of S/P was calculated and the cut-off value of 0.50 was determined to detect the *Neospora* positive samples using a receiver operator characteristic curve analysis (Fig. 1). This cutoff point distinguished nearly 100% of *Neospora* positive cases. The positive and negative controls were already validated with a commercial kit. The S/P ratio of 16 samples (19.27%) including three males (3.61%) and 13 females (15.66%) and also all positive controls were ≥ 0.50. The OD of samples in this group ranged from 0.52 to 2.13, 0.86 ± 0.43.

The statistical analysis showed that the level of antibody in all samples with S/P ratio ≥ 0.50 and also in the positive controls were significantly higher than those of the negative controls (*p* < 0.05). Amongst the negative samples, the levels of anti-*Neospora* antibody in 33 samples (39.75%) were significantly higher than those of the negative controls (S/P < 0.50). The range of OD in this group was between 0.054 to 0.465, 0.16 to 0.20, while in non-significant negative samples (34 samples, 40.96%) the range of OD was between 0.013 to 0.424 and 0.11 to 0.16.

All statistical analyses were calculated with 95.00% confidence interval (Fig. 2). The prevalence of the parasitemia was evaluated by detection of the parasite DNA in the serum samples using PCR (Fig. 3) and nested PCR (Fig. 4).

The parasite DNA was detected in all samples with the S/P ratio ≥ 0.50 and all samples with the S/P ratio bellow 0.50 were negative for the parasite DNA.
**Discussion**

Because of the economical importance of water buffalo in the livestock industry and the lack of comprehensive information about *Neospora* infection in buffalo, the rate of infection as well as the relationship between parasitemia and production of anti-*Neospora* antibody in the serum of water buffalo in northwest of Iran was investigated. For detection of anti-*Neospora* antibody, an ELISA method was developed to detect the level of antibody in the serum using the whole *Neospora* cells. In this method of ELISA, instead of using the parasite proteins, the plates were coated with *Neospora* cells for 72 hr. The ELISA is shown to be a rapid and reliable method to analyze a large number of samples in a short time and the new whole cell-based ELISA showed to be capable of detecting anti-*Neospora* antibody in the water buffalo serum; since all positive samples tested by other commercial kits were positive and also negative samples were negative. The results showed that the rate of infection of water buffalo in the northwest of Iran was 19.27%. In another study, the infection rate of *Neospora* in buffalo was reported as 37.10% in the southwest of Iran. The different rate of *Neospora* infection between various regions is also reported in Thailand. Indeed, the difference in the rate of infection between the regions could be due to the epidemiology of the parasite in the regions including the rate of infection in dogs and other definitive hosts. In previous studies, the prevalence rate of *N. caninum* in water buffalo has been reported around the world; up to 1.50% in southern Vietnam, 64.00% in Argentina, 52.30% in India, 64.00% in southern Brazil, 70.90% in the northern region of Brazil, 34.60% in Italy, 28.00% in Turkey and 68.00% in Egypt. The difference in the infection rate is probably due to the environmental and management conditions or differences in the methods used for detection of the infection. The rate of infection in other intermediate hosts has also been evaluated in Iran and other countries. Many studies have shown that the rate of *Neospora* infection in water buffalo is higher than that of other intermediate hosts. The seroprevalence of antibody to *N. caninum* in cattle was 10.50% in Tabriz (northwest of Iran). In Mashhad (northeast of Iran), the infection rate of *N. caninum* in dairy cattle and camels was 15.18% and 5.83%, respectively. In northern Australia, *N. caninum* infection in water buffalo was highly endemic and the infection rate was higher than that for cattle. It is thought that the higher rate of the infection in buffalo comes from this fact that this animal is probably more sensitive and its life style is slightly different than other intermediate hosts. The PCR is a technique which has recently been widely used for detection of *Neospora* infections. In most of *Neospora* studies, PCR is performed using tissues of aborted fetus or blood cells. In the present study, to determine the presence of the parasite in the blood, serum samples were directly examined by PCR and nested PCR for amplification of *Neospora* Nc-5 gene which is specific for detection of *Neospora*. The results showed that the *Neospora* DNA was detectable in all samples with the S/P ratio ≥ 0.50. None of the samples with the S/P ratio less than 0.50 contained *Neospora* DNA, however, some of the DNA negative samples with the cutoff value of less than 0.50 showed significant levels of antibody (p-value in t-test below 0.05). The *Neospora* DNA has yet been isolated from sheep and cattle serum, but this is the first report on the isolation of *Neospora* from the serum of water buffalo. In another study, the infection rate of *Neospora* in buffalo was reported as 37.10% in the southwest of Iran. This was in contrast with our findings in buffalo, where we used the serum as a DNA template in PCR reaction without any purification process. This controversy indicates that after an increase in the level of antibody in the serum, the parasites are removed from the blood, but they still grow inside the blood cells. However, the relation between the parasitemia and level of anti-*Neospora* antibody in the serum is more complicated and still needs to be more clear. The concurrent presence of the parasite and antibody in the serum is an important phenomenon in buffalo and needs to be investigated in cattle as the main intermediate hosts for the parasite. Our results showed a rate of 19.27% for...
Neospora caninum infection in water buffalo in the northwest of Iran. A 100% concurrency was observed between the high levels of anti-Neospora antibody and parasitemia during Neospora life stages in buffalo.

Acknowledgments

The authors would like to thank the Department of Clinical Sciences, Faculty of Veterinary Medicine, Urmia University, Urmia, Iran for helping in the collection of samples, Razi Vaccine and Serum Research Institute, Shiraz, Iran for the generous donation of the N. caninum isolate and Miss Sakineh Azami and Mr. Hossein Khoshrouzi for their technical assistance.
