MODULI OF REGULAR SINGULAR PARABOLIC CONNECTIONS OF SPECTRAL TYPE ON SMOOTH PROJECTIVE CURVES

MICHIAKI INABA AND MASAHIKO SAITO

ABSTRACT. We define a moduli space of stable regular singular parabolic connections of spectral type on smooth projective curves and show the smoothness of the moduli space and give a relative symplectic structure on the moduli space. Moreover, we define the isomonodromic deformation on this moduli space and prove the geometric Painlevé property of the isomonodromic deformation.

INTRODUCTION

Let $T$ be a smooth covering of the moduli stack of $n$-pointed smooth projective curves of genus $g$. Take a universal family $(\mathcal{C}, \hat{t})$ over $T$. In the paper [4], the first author constructed the relative moduli space

$$M^\alpha_{C/T}(\hat{t}, r, d) \to T \times \Lambda_r^{(n)}(d)$$

of regular singular $\alpha$-stable parabolic connections of rank $r$ and degree $d$ on $\mathcal{C}/T$. Here $\alpha = (\alpha_{i,j})_{1 \leq i,j \leq r}$ are rational numbers such that $0 < \alpha_{1} < \cdots < \alpha_{r} < 1$ and that $\alpha_{i,j} \neq \alpha_{i',j'}$ for any $(i,j) \neq (i',j')$. $\Lambda_r^{(n)}(d)$ is given by

$$\Lambda_r^{(n)}(d) := \left\{ (\lambda_i)_{1 \leq i \leq n} \in \mathbb{C}^r \mid d + \sum_{i=1}^{n-1} \sum_{j=0}^{r-1} \lambda_i = 0 \right\}.$$

Then for any point $(x, \lambda) \in T \times \Lambda_r^{(n)}(d)$, the fiber $M^\alpha_{C/T}(\hat{t}, r, d)_{(x, \lambda)}$ is smooth of dimension $2r^2(g-1) + nr(r-1) + 2$. He also constructed the algebraic splitting

$$D : \pi^*(\Theta_T) \to \Theta_{M^\alpha_{C/T}(\hat{t}, r, d)}$$

of the canonical surjection $\Theta_{M^\alpha_{C/T}(\hat{t}, r, d)} \to \pi^*(\Theta_T)$, where $\pi : M^\alpha_{C/T}(\hat{t}, r, d) \to T$ is the structure morphism. The subbundle $D(\pi^*(\Theta_T)) \subset \Theta_{M^\alpha_{C/T}(\hat{t}, r, d)}$ satisfies the integrability condition and the associated foliation $\mathcal{F}_{M^\alpha_{C/T}(\hat{t}, r, d)}$ is nothing but the isomonodromic deformation. One of the important results in [4] is that the isomonodromic deformation determined by $D(\pi^*(\Theta_T))$ has the geometric Painlevé property.

There is a locus $Y$ in $M^\alpha_{C/T}(\hat{t}, r, d)$ such that $(E, \nabla, \{l_{i,j}^{(i)}\}) \in M^\alpha_{C/T}(\hat{t}, r, d)$ lies in $Y$ if and only if the residue matrix of $\nabla$ at $t_i$ is given by

$$
\begin{pmatrix}
\mu_1^{(i)} I_{r_{s_i-1}} & * & * \\
0 & \mu_2^{(i)} I_{r_{s_i-2}} & * \\
\vdots & \vdots & \ddots & \ddots \\
0 & 0 & \cdots & \mu_r^{(i)} I_{r_0}
\end{pmatrix}.
$$

We can easily see that the locus $Y$ is preserved by the isomonodromic deformation. However, the dimension of $Y$ is too big because it parameterizes the parabolic structure $\{l_{i,j}^{(i)}\}$. So we contract $Y$ by forgetting the data $\{l_{i,j}^{(i)}\}$ and obtain a moduli space $\mathcal{T}$. We say $\mathcal{T}$ the moduli space of regular singular parabolic connections of spectral type $(\hat{t})$. By construction, $\mathcal{T}$ is preserved by the isomonodromic deformation. So we obtain a low dimensional phase space arising from the isomonodromic deformation. Such low dimensional phase spaces get an attention from the viewpoint of the theory of integrable systems.

T. Oshima studied in [9] the isomonodromic deformation of the Fuchsian system of spectral types in detail. In particular, he studied additive Deligne-Simpson problem on Fuchsian systems on trivial bundles on $P^1$ and a combinatorial structure of middle convolutions and their relation to a Kac-Moody root system discovered by Crawley-Boevey [1].

Let us fix a smooth projective curve $C$ of genus $g$ and a set of $n$-distinct points $t = (t_1, \cdots, t_n)$ on $C$. Spectral types are given by tuples $(r_j^{(i)})_{0 \leq j \leq s_i-1}$ of partitions of integers, where $r$ is a fixed rank of vector bundles and at each singular point $t_i$, $r_i^{(i)}$ are positive integers such that $\sum_{j=0}^{s_i-1} r_{j}^{(i)} = r$. Fixing a degree $d$ and a spectral type $(r_j^{(i)})_{0 \leq j \leq s_i-1}$, let us take any local exponents $\nu \in N(d, (r_j^{(i)})_{1 \leq i \leq n})$ (see [4]). Then we can define the moduli space $M^\alpha(C, t, \nu, d, (r_j^{(i)}))$ of $\alpha$-stable $\nu$-parabolic connections on $(C, t)$ of spectral type $(r_j^{(i)})$. In §1, we show that $M^\alpha(C, t, \nu, d, (r_j^{(i)}))$ is a smooth quasi-projective scheme of dimension (see Theorem 13)

$$\dim M^\alpha(C, t, \nu, d, (r_j^{(i)})) = 2r^2(g-1) + 2 + 2 \sum_{i=1}^{n} \sum_{j=0}^{s_i-1} r_{j}^{(i)} r_{j'}^{(i)}.$$

If we set

$$N = r^2(g-1) + 1 + n \frac{r(r-1)}{2},$$

one can rewrite as

$$\dim M^\alpha(C, t, \nu, d, (r_j^{(i)})) = 2(N - \sum_{i=1}^{n} \sum_{j=0}^{s_i-1} \frac{r_{j}^{(i)} (r_{j}^{(i)} - 1)}{2}).$$

The moduli space of $\alpha$-stable parabolic connections of spectral types $(r_j^{(i)})$ is a deformation of the moduli space of $\alpha$-stable parabolic Higgs bundles on $(C, t)$ of spectral types $(r_j^{(i)})$. Then the genus of spectral curves of parabolic Higgs bundles should be the half of dimension of the moduli spaces. The formula suggests that the genus of spectral curves equal to $N - \sum_{i=1}^{n} \sum_{j=0}^{s_i-1} \frac{r_{j}^{(i)} (r_{j}^{(i)} - 1)}{2}$ where $N$ is the genus of spectral curve with trivial spectral types $r_j^{(i)} = 1$. It will be interesting to see the explicit geometry of the moduli space of parabolic connections and parabolic Higgs bundles. An approach by using the apparent singularities and their duals will be treated in [10].

For example, if we consider the case $g = 0, n = 4, r = 2, d = -1$ and $r_j^{(i)} = 1$ for all $i, j$, then the spectral type will be denoted as $(11, 11, 11, 11, 11)$. The corresponding moduli spaces $M$ are nothing but the fiber of the phase space, or Okamoto’s space of initial conditions of Painlevé VI equations and dim $M = 2$.

H. Sakai studied in [11] the Fuchsian system of spectral type which gives 4-dimensional isomonodromic deformation equations. Here the 4-dimensional means that the dimension of the moduli space of parabolic connection of spectral type is 4. The interesting point of [11] is that a Fuji-Suzuki system ([2], [3]) and a Sasano system ([12]) can be obtained from the isomonodromic deformations of the Fuchsian system of certain spectral types. Including them, there exists only 4-types of 4-dimensional isomonodromic deformation equations of Fuchsian systems of spectral types over $P^1$. They are corresponding to the spectral types $r = 2, n = 5, (11, 11, 11, 11, 11)$ (Garnier), $r = 3, n = 4, (21, 21, 111, 1111)$ (the Fuji-Suzuki), $r = 4, n = 4, (31, 22, 22, 11111)$ (Sasano) and $r = 4, n = 4, (22, 22, 22, 2211)$ (the sixth matrix Painlevé).

The main results in this paper are the smoothness and a symplectic structure of the moduli space of stable regular singular parabolic connections of any spectral type on smooth projective curves over $C$. (Cf. Theorem 12 and Theorem 5.1). Moreover, the more important result (cf. Theorem 4.1) is that the isomonodromic deformation defined on the moduli space of regular singular parabolic connections of spectral type has the geometric Painlevé property. So we can say that the moduli space of stable regular singular parabolic connections of spectral type is the space of initial conditions for the isomonodromic deformations.

Here the definition of the geometric Painlevé property is given in [6] and the geometric Painlevé property implies the usual Painlevé property.

As a corollary, 4-dimensional isomonodromic deformation considered by H. Sakai in [11] has the Painlevé property.

It will be also interesting to consider similar problems for parabolic connections with irregular singularities of fixing spectral types. Classifications of spectral types of dimension 4 cases are treated in [7] and [8].
1. Definition and properties of the moduli space of regular singular parabolic connections of spectral type

Let $C$ be a smooth projective irreducible curve over $\mathbb{C}$ of genus $g$. We set

$$T_n := \{ t = (t_1, \ldots, t_n) \in C \times \cdots \times C | t_i \neq t_j \text{ for } i \neq j \}. $$

Let $r, d$ be integers with $r > 0$. For each $i$ with $1 \leq i \leq n$, take positive integers $r_0^{(i)}, \ldots, r_{s_i-1}^{(i)}$ such that $r = \sum_{j=0}^{s_i-1} r_j^{(i)}$ for any $i$. Set

$$N(d, (r_j^{(i)})) := \left\{ \left( \nu_j^{(i)} \right)_{0 \leq j \leq s_i-1} | \nu_j^{(i)} \in \mathbb{C} \text{ for any } i, j \text{ and } d + \sum_{i=1}^n \sum_{j=0}^{s_i-1} r_j^{(i)} \nu_j^{(i)} = 0 \right\}. $$

**Definition 1.1.** Take $t \in T_n$ and $\nu = (\nu_j^{(i)}) \in N(d, (r_j^{(i)}))$. We say $(E, \nabla, \{ l_j^{(i)} \})$ is a regular singular $(t, \nu)$-parabolic connection of spectral type $(r_j^{(i)})$ if

1. $E$ is a vector bundle on $C$ of rank $r$ and degree $d$,
2. $\nabla: E \to E \otimes \Omega_C^1(t_1 + \cdots + t_n)$ is a connection,
3. for each $i$, $E|_{t_i} = l_0^{(i)} \supset l_1^{(i)} \supset \cdots \supset l_{s_i}^{(i)} = 0$ is a filtration such that $\dim_{\mathbb{C}} (l_j^{(i)}/l_{j+1}^{(i)}) = r_j^{(i)}$ and
4. $(\text{res}_{t_i}(\nabla) - \nu_j^{(i)} \text{id})(l_j^{(i)}) \subset l_{j+1}^{(i)}$ for any $i, j$.

Take rational numbers $\alpha = (\alpha_j^{(i)})_{1 \leq j \leq s_i}$, such that $0 < \alpha_1^{(i)} < \alpha_2^{(i)} < \cdots < \alpha_{s_i}^{(i)} < 1$ for any $i, j$ and $\alpha_j^{(i)} \neq \alpha_{j'}^{(i')}$ for $(i, j) \neq (i', j')$.

**Definition 1.2.** A regular singular $(t, \nu)$-parabolic connection $(E, \nabla, \{ l_j^{(i)} \})$ of spectral type $(r_j^{(i)})$ is said to be $\alpha$-stable (resp. $\alpha$-semistable) if

$$\frac{\deg F + \sum_{i=1}^n \sum_{j=1}^{s_i} \alpha_j^{(i)} \dim_{\mathbb{C}}((F|_{t_i} \cap l_j^{(i)})/(F|_{t_i} \cap l_{j+1}^{(i)}))}{\text{rank } F} < \frac{\deg E + \sum_{i=1}^n \sum_{j=1}^{s_i} \alpha_j^{(i)} \dim_{\mathbb{C}}(l_j^{(i)}/l_{j+1}^{(i)})}{\text{rank } E}$$

for any subbundle $0 \neq F \subseteq E$ with $\nabla(F) \subset F \otimes \Omega_C^1(t_1 + \cdots + t_n)$.

Let $T$ be a smooth algebraic scheme which is a smooth covering of the moduli stack of n-pointed smooth projective irreducible curves of genus $g$ over $\mathbb{C}$ and $(C, t)$ be the universal family over $T$ ($t = (t_1, \ldots, t_n)$), where each $t_i$ is a section of $C \to T$ and $t_i \cap t_j = \emptyset$ for any $i \neq j$.

**Theorem 1.1.** There exists a relative coarse moduli space $\pi: M_{C/T}^\alpha(d, (r_j^{(i)})) \to T \times N(d, (r_j^{(i)}))$ of $\alpha$-stable regular singular parabolic connections of spectral type $(r_j^{(i)})$. Moreover $\pi$ is a quasi-projective morphism.

**Proof.** Proof is the same as that of [3, Theorem 2.1] which essentially uses [5, Theorem 5.1] and we omit the proof here. \qed

**Theorem 1.2.** The relative moduli space $\pi: M_{C/T}^\alpha(d, (r_j^{(i)})) \to T \times N(d, (r_j^{(i)}))$ is smooth.

**Proof.** Let $M_{C/T}(d, (1))$ be the moduli space of pairs $(L, \nabla_L)$ of a line bundle $L$ on $C$ and a connection $\nabla_L : L \to L \otimes \Omega_C^1(t_1 + \cdots + t_n)$. Then $M_{C/T}(d, (1))$ is an affine space bundle over $\text{Pic}^d_{C/T} \times N(d, (1))$, where

$$N(d, (1)) := \left\{ \left( \nu_j^{(i)} \right) \in \mathbb{C}^n | d + \sum_{i=1}^n \nu_j^{(i)} = 0 \right\}. $$

Since $\text{Pic}^d_{C/T}$ is smooth over $T$, $M_{C/T}(d, (1))$ is smooth over $T \times N(d, (1))$. Consider the morphism

$$\text{det}: M_{C/T}^\alpha(d, (r_j^{(i)})) \to M_{C/T}(d, (1)) \times N(d, (1)) \times N(d, (r_j^{(i)}));$$

$$(E, \nabla, \{ l_j^{(i)} \}) \to ((\text{det}(E), \text{det}(\nabla)), \pi(E, \nabla, \{ l_j^{(i)} \}))$$

It is sufficient to show that the morphism $\text{det}$ is smooth. Let $A$ be an artinian local ring over $M_{C/T}(d, (1)) \times N(d, (1))$ with the maximal ideal $m$ and $I$ be an ideal of $A$ such that $mI = 0$. Let $(L, \nabla_L) \in M_{C/T}(d, (1)) \times N(d, (r_j^{(i)}))$ and $\nu = (\nu_j^{(i)}) \in N(d, (r_j^{(i)}))$ be the elements corresponding to the morphism $\text{Spec} A \to M_{C/T}(d, (1)) \times N(d, (1))$.
N(d, (ρ_j(1)). Take any member (E, ∇, {l_j(1)}) ∈ M^0_{C/T}(d, (ρ_j(1)))(A/I) such that (res_{t×A/I}(∇) − ρ_j(1)id)(l_j(1)) ⊂ l_{j+1}(1) for any i, j. and that det(E, ∇, {l_j(1)}) ≃ (L, ∇_L, ν) ⊗ A/I. It is sufficient to show that (E, ∇, {l_j(1)}) can be lifted to a flat family (♯, ∇, {♯_j(1)}) over A such that det(♯, ∇, {♯_j(1)}) ≃ (L, ∇_L, ν). We define a complex F^0 by

\[ F^0 := \{ a ∈ End(E ⊗ A/m) | Tr(a) = 0 \text{ and } a|_{t×A/m}((l_j(1))A/m) ⊂ (l_j(1))A/m \text{ for any } i, j \} \]

\[ F^1 := \{ b ∈ End(E ⊗ A/m) ⊗ \Omega^1_{C/T}(♯_1 + ⋯ + ♯_n) | Tr(b) = 0 \text{ and } res_{t×A/m}(b)((l_j(1))A/m) ⊂ (l_{j+1}(1))A/m \text{ for any } i, j \} \]

\[ F^r_0 \ni a → ∇ \circ a - a \circ ∇ ∈ F^0. \]

Let C_A = \bigcup_a U_a be an affine open covering such that E|_{U_a} ⊗ A/I ≃ O_{U_a}^r ⊗ A/I, and that \{♯(t_i)A | (♯_i)A ∈ U_a \} ≤ 1 for any α and ≥ A(I). Take a free O_{U_a}-module E_α of rank r with isomorphisms \varphi_α: det(E_α) → L|_{U_a} and φ_α: E_α ⊗ A/I → E|_{U_a} ⊗ A/I such that

\[ φ_α ⊗ A/I = det(φ_α): det(E_α) → det(E)|_{U_a} ⊗ A/I = (L ⊗ A/I)|_{U_a} ⊗ A/I. \]

If (♯_i)A ∈ U_a, we may assume that the parabolic structure \{l_j(1)\} is given by

\[ l_j(1) = (e_1|_{♯(t_i)A}, ⋯, e_r|_{♯(t_i)A}) \]

where e_1, ⋯, e_r is the standard basis of E_α. We define a parabolic structure \{(l_α)j\} on E_α by

\[ (l_α)j := (e_1|_{♯(t_i)A}, ⋯, e_r|_{♯(t_i)A}) \]

The connection φ_α^{-1} ○ (∇|_{U_a}) ○ φ_α: E_α ⊗ A/I → E_α ⊗ \Omega^1_{C/T}(♯_1 + ⋯ + ♯_n) ⊗ A/I is given by a connection matrix \overline{B}_α ∈ H^0(E_α ⊗ E_α ⊗ \Omega^1_{C/T}(♯_1 + ⋯ + ♯_n) ⊗ A/I). Then we have

\[ res_{♯(t_i)A}(\overline{B}_α) = \begin{pmatrix} (ν_{s_1} ⊗ A/I)I_{s_1} & * & ⋯ & * \\ 0 & (ν_{s_2} ⊗ A/I)I_{r_2} & ⋯ & * \\ ⋮ & ⋮ & ⋱ & ⋮ \\ 0 & 0 & ⋯ & (ν_0 ⊗ A/I)I_{r_0} \end{pmatrix}, \]

where I_{r_0} is the identity r_0 × r_0 matrix. We can take a lift B_α ∈ H^0(E_α ⊗ E_α ⊗ \Omega^1_{C/T}(♯_1 + ⋯ + ♯_n)) of \overline{B}_α such that

\[ res_{♯(t_i)A}(B_α) = \begin{pmatrix} (ν_{s_1} ⊗ A/I)I_{s_1} & * & ⋯ & * \\ 0 & (ν_{s_2} ⊗ A/I)I_{r_2} & ⋯ & * \\ ⋮ & ⋮ & ⋱ & ⋮ \\ 0 & 0 & ⋯ & (ν_0 ⊗ A/I)I_{r_0} \end{pmatrix}. \]

and that \text{Tr}(B_α)(e_1 ∧ ⋯ ∧ e_r) = (φ_α ⊗ id)^{-1}(∇L|_{U_a}(φ_α(e_1 ∧ ⋯ ∧ e_r))). Consider the connection ∇_α: E_α → E_α ⊗ \Omega^1_{C/T}(♯_1 + ⋯ + ♯_n) defined by

\[ ∇ \begin{pmatrix} f_1 \\ ⋮ \\ f_r \end{pmatrix} = \begin{pmatrix} df_1 \\ ⋮ \\ df_r \end{pmatrix} + B_α \begin{pmatrix} f_1 \\ ⋮ \\ f_r \end{pmatrix}. \]

Then we obtain a local parabolic connection (E_α, ∇_α, \{(l_α)j\}) on U_α. If (♯_i)A \not∈ U_α for any i, then we can easily obtain a local parabolic connection (E_α, ∇_α, \{(l_α)j\}) on U_α (in this case, a parabolic structure \{(l_α)j\} is nothing). We put U_{αβ} := U_α ∩ U_β and U_{αβγ} := U_α ∩ U_β ∩ U_γ. Take an isomorphism

\[ θ_{βα}: E_α|_{U_{αβ}} → E_β|_{U_{αβ}}. \]
such that \( \theta_{\beta \alpha} \otimes A/I = \phi_{\beta}^{-1} \circ \phi_{\alpha} \) and that \( \varphi_{\beta} \circ \det(\theta_{\beta \alpha}) = \varphi_{\alpha} \). We put
\[
\begin{align*}
  u_{\alpha \beta r} & := \phi_{\alpha} \circ \left( \theta_{\gamma \alpha}^{-1} |_{u_{\alpha \beta r}} \cdot \theta_{\alpha \beta} |_{u_{\alpha \beta r}} \cdot \theta_{\beta \alpha} |_{u_{\alpha \beta r}} - \text{id}_{E_{\alpha}|_{u_{\alpha \beta r}}} \right) \circ \phi_{\alpha}^{-1},
  \\
v_{\alpha \beta} & := \phi_{\alpha} \circ \left( \nabla_{\alpha} |_{u_{\alpha \beta}} - \theta_{\gamma \alpha}^{-1} \circ \nabla_{\beta} |_{u_{\alpha \beta}} \circ \theta_{\alpha \beta} \right) \circ \phi_{\alpha}^{-1}.
\end{align*}
\]
and then we have \( \{ u_{\alpha \beta r} \} \in C^2(\{ U_{\alpha} \}, F_r^0 \otimes I) \) and \( \{ v_{\alpha \beta} \} \in C^1(\{ U_{\alpha} \}, F_0^1 \otimes I) \). We can easily see that
\[
d \{ u_{\alpha \beta r} \} = 0 \quad \text{and} \quad \nabla^\dagger \{ u_{\alpha \beta r} \} = -d \{ v_{\alpha \beta} \}.
\]
So we can define an element
\[
\omega(E, \nabla, \{ t^{(i)}_j \}) := \{ u_{\alpha \beta r} \}, \{ v_{\alpha \beta} \} \in \mathbf{H}^2(F_0^*) \otimes I.
\]
We can check that \( \omega(E, \nabla, \{ t^{(i)}_j \}) = 0 \) if and only if \( (E, \nabla, \{ t^{(i)}_j \}) \) can be lifted to a flat family \( (\tilde{E}, \tilde{\nabla}, \{ \tilde{t}^{(i)}_j \}) \) over \( A \) such that \( \det(\tilde{E}, \tilde{\nabla}, \{ \tilde{t}^{(i)}_j \}) \cong ((L, \nabla_L), \nu) \). From the spectral sequence \( H^q(F^0_r) \Rightarrow H^{p+q}(F^*_0) \), there is an isomorphism
\[
\mathbf{H}^2(F^*_0) \cong \text{coker} \left( H^1(F^0_0) \rightarrow H^1(\nabla_1) \right).
\]
Since \( (F^0_0)^\vee \otimes \Omega^1_{C/T} \cong F^0_1 \) and \( (F^1_0)^\vee \otimes \Omega^1_{C/T} \cong F_1^0 \), we have
\[
\begin{align*}
\mathbf{H}^2(F^*_0) & \cong \text{coker} \left( H^1(F^0_0) \rightarrow H^1(\nabla_1) \right) \\
& \cong \ker \left( H^1(F^1_0) \rightarrow H^1(\nabla_1) \right) \\
& \cong \ker \left( H^0(\nabla_0^0) \otimes \Omega^1_{C/T} \rightarrow H^0(\nabla_1) \right) \\
& \cong \ker \left( H^0(F^0_0) \rightarrow H^0(\nabla_1) \right).
\end{align*}
\]
Take any element \( a \in \ker \left( H^0(F^0_0) \rightarrow H^0(\nabla_1) \right) \). Then we have \( a \in \text{End}((E, \nabla, \{ t^{(i)}_j \}) \otimes A/m) \). Since \( (E, \nabla, \{ t^{(i)}_j \}) \otimes A/m \) is \( \alpha \)-stable, we have \( a = c \cdot \text{id}_{E \otimes A/m} \) for some \( c \in A/m \). So we have \( a = 0 \), because \( \text{Tr}(a) = 0 \). Thus we have \( \ker \left( H^0(F^0_0) \rightarrow H^0(\nabla_1) \right) = 0 \) and so we have \( \mathbf{H}^2(F^*) = 0 \). In particular, we have \( \omega(E, \nabla, \{ t^{(i)}_j \}) = 0 \). Thus \( (E, \nabla, \{ t^{(i)}_j \}) \) can be lifted to a flat family \( (\tilde{E}, \tilde{\nabla}, \{ \tilde{t}^{(i)}_j \}) \) over \( A \) such that \( (\tilde{E}, \tilde{\nabla}, \{ \tilde{t}^{(i)}_j \}) \otimes A/I \cong ((E, \nabla, \{ t^{(i)}_j \}) \) and that \( \det(\tilde{E}, \tilde{\nabla}, \{ \tilde{t}^{(i)}_j \}) = ((L, \nabla_L), \nu) \). Hence \( \det \) is a smooth morphism.

**Theorem 1.3.** For any \((x, \nu) \in T \times N(d, (r^{(i)}_j))\), the fiber \( M^\alpha_{C/T}(d, (r^{(i)}_j))(x, \nu) := \pi^{-1}(x, \nu) \) is of equidimension \( 2r^2(g - 1) + 2 + 2 \sum_{i=1}^n \sum_{j=0}^{s_i - 1} \sum_{j' > j} r^{(i)}_j r^{(i)}_{j'} = 2r^2(g - 1) + 2 + nr(r - 1) - \sum_{i=1}^n \sum_{j=0}^{s_i - 1} r^{(i)}_j (r^{(i)}_{j'} - 1) \) if \( M^\alpha_{C/T}(d, (r^{(i)}_j))(x, \nu) \neq \emptyset \).

**Proof.** Since \( M^\alpha_{C/T}(d, (r^{(i)}_j))(x, \nu) \) is smooth, it is sufficient to show that the tangent space \( \Theta_{M^\alpha_{C/T}(d, (r^{(i)}_j))(x, \nu)}(y) \) of \( M^\alpha_{C/T}(d, (r^{(i)}_j))(x, \nu) \) at any point \( y = (E, \nabla, \{ t^{(i)}_j \}) \in M^\alpha_{C/T}(d, (r^{(i)}_j))(x, \nu) \) is of dimension
\[
2r^2(g - 1) + 2 + 2 \sum_{i=1}^n \sum_{j'=j}^{s_i - 1} r^{(i)}_j r^{(i)}_{j'}.
\]
Set
\[
\begin{align*}
  \mathcal{F}^0 & := \left\{ a \in \text{End}(E) \mid a_{(i_j)_i}(t^{(i)}_j) \subset t^{(i)}_j \right\} \quad \text{for any } i, j \\
  \mathcal{F}^1 & := \left\{ b \in \text{End}(E) \otimes \Omega^1_{C/T}(t_1 + \cdots + t_n) \mid \text{res}_{(i_j)_i}(b)(t^{(i)}_j) \subset t^{(i)}_j \right\} \quad \text{for any } i, j \\
  \nabla^\dagger : \mathcal{F}^0 & \ni a \mapsto \nabla \circ a - a \circ \nabla \in \mathcal{F}^1
\end{align*}
\]
Note that we have an isomorphism

$$\Theta_{M^b_{C/F}(d,(r^{(i)}_j))} \cong H^1(F^\bullet),$$

where $$\Theta_{M^b_{C/F}(d,(r^{(i)}_j))}$$ is the algebraic relative tangent bundle of $$M^b_{C/F}(d,(r^{(i)}_j))$$ over $$T \times N(d,(r^{(i)}_j)).$$

From the spectral sequence $$H^p(F^q) \Rightarrow H^{p+q}(F^\bullet),$$ we obtain an exact sequence

$$0 \rightarrow C \rightarrow H^0(F^0) \rightarrow H^0(F^1) \rightarrow H^1(F^\bullet) \rightarrow H^1(F^0) \rightarrow H^1(F^1) \rightarrow C \rightarrow 0.$$

So we have

$$\dim H^1(F^\bullet) = \dim H^0(F^1) + \dim H^1(F^0) - \dim H^0(F^0) - \dim H^1(F^1) + 2 \dim_C C$$

$$= \dim H^0((F^0) \vee \Omega^1_{C/T}) + \dim H^1(F^0) - \dim H^0(F^0) - \dim H^1(F^0) \vee + 2$$

$$= 2 - 2\chi(F^0).$$

Here we used the isomorphism $$F^1 \cong (F^0) \vee \Omega^1_{C/T}$$ and Serre duality. We define a subsheaf $$E_1 \subset End(E)$$ by the exact sequence

$$0 \rightarrow E_1 \rightarrow End(E) \rightarrow \bigoplus_{i=1}^n \text{Hom}(l^{(i)}_1, l^{(i)}_0/l^{(i)}_1) \rightarrow 0.$$ 

Inductively we define a subsheaf $$E_k \subset End(E)$$ by the exact sequence

$$0 \rightarrow E_k \rightarrow E_{k-1} \rightarrow \bigoplus_{i=1}^n \text{Hom}(l^{(i)}_k, l^{(i)}_{k-1}/l^{(i)}_k) \rightarrow 0.$$ 

Then we have $$E_{\max,{n,s_i-1}} = F^0$$ and

$$\chi(F^0) = \chi(End(E)) - \sum_{i=1}^n \sum_{j=1}^{s_i-1} \dim \text{Hom}(l^{(i)}_j, l^{(i)}_j/l^{(i)}_j)$$

$$= r^2(1-g) - \sum_{i=1}^n \sum_{j=1}^{s_i-1} \sum_{j'=j}^{s_i-1} r^{(i)}_{j-1}r^{(i)}_{j'}.$$ 

So we have

$$\dim H^1(F^\bullet) = 2 - \chi(F^0) = 2r^2(g - 1) + 2 + 2 \sum_{i=1}^n \sum_{j=0}^{s_i-1} \sum_{j'=j}^{s_i-1} r^{(i)}_{j-1}r^{(i)}_{j'},$$

$$\square$$

2. Riemann-Hilbert Correspondence

Let $$T, C$$ and $$\tilde{t} = (\tilde{t}_1, \ldots, \tilde{t}_n)$$ be as in section 1. Take a point $$x \in T.$$ Then $$C_x$$ is a smooth projective curve of genus $$g$$ over $$C$$ and $$(\tilde{t}_1)_x, \ldots, (\tilde{t}_n)_x$$ are distinct points of $$C_x.$$ Consider the categorical quotient

$$RP_r(C_x, \tilde{t}_x) := \text{Hom}(\pi_1(C_x \setminus \{(\tilde{t}_1)_x, \ldots, (\tilde{t}_n)_x\}, \ast), GL_r(C))/GL_r(C)$$

by the adjoint action. We set

$$B := \left\{ b := (b_j^{(i)})_{0 \leq j \leq s_i-1} \prod_{i=1}^n \prod_{j=0}^{s_i-1} (b_j^{(i)})^{r^{(i)}} = 1 \right\}.$$ 

For $$b \in B$$ and $$x \in T,$$ we denote by $$RP_r(C_x, \tilde{t}_x, b)$$ the categorical quotient of

$$\rho \in \text{Hom}(\pi_1(C_x \setminus \{(\tilde{t}_1)_x, \ldots, (\tilde{t}_n)_x\}, \ast), GL_r(C))$$

for each $$i,$$ there is a filtration

$$C^r = W_0^{(i)} \supset W_1^{(i)} \supset \cdots \supset W_{s_i-1}^{(i)} \supset W_{s_i}^{(i)} = 0$$

such that $$(\rho(\gamma_i) - b_j^{(i)}\text{id})|W_j^{(i)} \subset W_{j+1}^{(i)}$$ for any $$i, j.$$ 

by the adjoint action of $$GL_r(C),$$ where $$\gamma_i$$ is a loop around $$(\tilde{t}_i)_x.$$ Then we have a canonical closed immersion

$$RP_r(C_x, \tilde{t}_x, b) \hookrightarrow RP_r(C_x, \tilde{t}_x).$$
For $\nu \in N(d,(r_j^{(i)}))$, consider the moduli space $M^\alpha_{\mathcal{C}/T}(d,(r_j^{(i)}))(x,\nu)$. We define $b = (b_j^{(i)}) = rh(\nu)$ by

$$b_j^{(i)} = \exp(-2\pi \sqrt{-1} \nu_j^{(i)})$$

for any $i,j$. For $(E, \nabla, \{l_j^{(i)}\}) \in M^\alpha_{\mathcal{C}/T}(d,(r_j^{(i)}))(x,\nu)$, ker $\nabla_{an} \mid \mathcal{C}_x \setminus \{l_1^{(i)}, \ldots, l_n^{(i)}\}$ becomes a local system and corresponds to a representation $\rho : \pi_1(\mathcal{C}_x \setminus \{l_1^{(i)}, \ldots, l_n^{(i)}\},*) \to GL_r(\mathbb{C})$. Then we put $RH(E, \nabla, \{l_j^{(i)}\}) := [p] \in \text{RP}_r(\mathcal{C}_x, \tilde{t}_x, b)$. So we can define a morphism

$$RH : M^\alpha_{\mathcal{C}/T}(d,(r_j^{(i)}))(x,\nu) \to \text{RP}_r(\mathcal{C}_x, \tilde{t}_x, b).$$

Consider the scheme

$$p : M^\alpha_{\mathcal{C}/T}(d,(r_j^{(i)})) \to M^\alpha_{\mathcal{C}/T}(d,(r_j^{(i)}))$$

such that for an affine scheme $U$ over $M^\alpha_{\mathcal{C}/T}(d,(r_j^{(i)}))$,

$$\tilde{M}^\alpha_{\mathcal{C}/T}(d,(r_j^{(i)}))(U) = \left\{ (V_j^{(i)}) \mid \begin{array}{c}
(t_j^{(i)}) / (t_j^{(i)})_{j+1} = V_j^{(i)} \supset V_j^{(i)} \supset \cdots \supset V_j^{(i)}_{j-1} \supset V_j^{(i)}_{j-1} = 0 \\
\text{is a filtration such that } V_j^{(i)} / V_j^{(i)}_{j+1} \text{ is a line bundle on } \tilde{t}_i \times U
\end{array} \right\},$$

where $M^\alpha_{\mathcal{C}/T}(d,(r_j^{(i)}))$ is the moduli functor of $\alpha$-stable regular singular parabolic connections of spectral type $(r_j^{(i)}$) and $(E, \nabla, \{l_j^{(i)}\})$ is the member corresponding to $U \to M^\alpha_{\mathcal{C}/T}(d,(r_j^{(i)}))$. Then $M^\alpha_{\mathcal{C}/T}(d,(r_j^{(i)}))$ is a flag scheme over $M^\alpha_{\mathcal{C}/T}(d,(r_j^{(i)}))$ and so $p$ is a smooth projective surjective morphism. A point of $M^\alpha_{\mathcal{C}/T}(d,(r_j^{(i)}))$ corresponds to a regular singular parabolic connection considered in [4]. Assume that we can choose $\alpha$ so that $\alpha$-stable $\Leftrightarrow$ $\alpha$-semistable. If we choose $\alpha' = ((\alpha')^{(i)}_{k})_{1 \leq k \leq r}$ suitably, any parabolic connection $(E, \nabla, \{l_j^{(i)}\}, \{V_j^{(i)}\})$ in $M^\alpha_{\mathcal{C}/T}(d,(r_j^{(i)}))$ is automatically $\alpha'$-stable. So we can define an inclusion

$$\iota : \tilde{M}^\alpha_{\mathcal{C}/T}(d,(r_j^{(i)})) \to M^\alpha_{\mathcal{C}/T}(\tilde{t}, r, d),$$

where $M^\alpha_{\mathcal{C}/T}(\tilde{t}, r, d)$ is the moduli space of $\alpha'$-stable regular singular parabolic connections defined in [4, Theorem 2.1]. If we take $\alpha'$ suitably, $\iota$ becomes a closed immersion.

For $\nu = (\nu_j^{(i)}) \in N(d,(r_j^{(i)}))$, we define $\nu' = ((\nu')^{(i)}_{k})_{1 \leq k \leq r}$ by $(\nu')^{(i)}_{j} = \nu_j^{(i)}$ if $q = m + \sum_{j' < j} r_{j'}^i$ with $0 \leq m \leq r_j^{(i)} - 1$. Now assume that $rn - 2r - 2 > 0$ if $g = 0$, $n > 1$ if $g = 1$ and $n \geq 1$ if $g = 2$. Since the Riemann-Hilbert morphism

$$RH : M^\alpha_{\mathcal{C}/T}(\tilde{t}, r, d)(x,\nu') \to \text{RP}_r(\mathcal{C}_x, \tilde{t}_x, b).$$

is a proper surjective morphism by [4], the restriction

$$RH |_{\tilde{M}^\alpha_{\mathcal{C}/T}(d,(r_j^{(i)}))(x,\nu')} : \tilde{M}^\alpha_{\mathcal{C}/T}(d,(r_j^{(i)}))(x,\nu) \to \text{RP}_r(\mathcal{C}_x, \tilde{t}_x, b)$$

is also proper. We have a commutative diagram

$$\begin{array}{ccc}
\tilde{M}^\alpha_{\mathcal{C}/T}(d,(r_j^{(i)}))(x,\nu) & \xrightarrow{p} & M^\alpha_{\mathcal{C}/T}(d,(r_j^{(i)}))(x,\nu) \\
\text{RH} \downarrow & & \text{RH} \\
\text{RP}_r(\mathcal{C}_x, \tilde{t}_x, b) & & \text{RP}_r(\mathcal{C}_x, \tilde{t}_x, b).
\end{array}$$

Since $p$ is surjective, the morphism

$$RH : M^\alpha_{\mathcal{C}/T}(d,(r_j^{(i)}))(x,\nu) \to \text{RP}_r(\mathcal{C}_x, \tilde{t}_x, b)$$

becomes a proper morphism.

**Remark 2.1.** D. Yamakawa gives in [43], 4.3, 4.4, the Riemann-Hilbert isomorphism from the moduli space $M^\alpha_{\mathcal{C}/T}(d,(r_j^{(i)}))(x,\nu)$ to the moduli space of stable filtered local systems which is constructed as a quiver variety. The properness of the morphism $RH : M^\alpha_{\mathcal{C}/T}(d,(r_j^{(i)}))(x,\nu) \to \text{RP}_r(\mathcal{C}_x, \tilde{t}_x, b)$ can be obtained also from this Yamakawa’s precise result.

**Remark 2.2.** It is somewhat a complicated problem whether the morphism $RH : M^\alpha_{\mathcal{C}/T}(d,(r_j^{(i)}))(x,\nu) \to \text{RP}_r(\mathcal{C}_x, \tilde{t}_x, b)$ defined above is surjective. For example, it happens that for $g = 0$ and for small $n$, the moduli space $M^\alpha_{\mathcal{C}/T}(d,(r_j^{(i)}))(x,\nu)$ becomes empty but the moduli space $\text{RP}_r(\mathcal{C}_x, \tilde{t}_x, b)$ is not empty.
3. Relative symplectic form on the moduli space

**Theorem 3.1.** Assume that we can take $\alpha$ so that $\alpha$-stable $\Leftrightarrow$ $\alpha$-semistable. Then there exists a relative symplectic form $\omega \in H^0 \left( M_{C/T}^\alpha(d, (r_j^{(i)})), \Omega^2_{M_{C/T}^\alpha(d, (r_j^{(i)}))/T \times N(d, (r_j^{(i)}))} \right)$.

**Remark 3.1.** We need some assumption on $(r_j^{(i)})$ for the existence of such $\alpha$. For example, if some $r_j^{(i)}$ is coprime to $r$, then we can take such $\alpha$.

**Proof.** There are an affine scheme $U$ and an étale surjective morphism $\tau : U \to M_{C/T}^\alpha(d, (r_j^{(i)}))$, which factors through the moduli functor $M_{C/T}^\alpha(d, (r_j^{(i)}))$, namely there is a universal family $(\tilde{E}, \tilde{\nabla}, \{\tilde{l}_j^{(i)}\})$ on $C \times T$. We define a complex $F_\bullet$ on $C \times T$ by

$$ F^0 := \left\{ a \in \text{End}(\tilde{E}) \mid a(l_{i,j}) \subset \tilde{l}_j^{(i)} \right\} \text{ for any } i, j 
$$

$$ F^1 := \left\{ b \in \text{End}(\tilde{E}) \otimes \Omega^1_{C/T}(\tilde{l}_1 + \cdots + \tilde{l}_n) \mid \text{res}(l_{i,j})(b) \subset \tilde{l}_j^{(i)} \right\} \text{ for any } i, j 
$$

$$ \nabla^1 : F^0 \ni a \mapsto \tilde{\nabla} \circ a - a \circ \tilde{\nabla} \in F^1. $$

Let $\pi_U : C \times T \to U$ be the projection. Then we have

$$ \Theta_{U/T \times N(d, (r_j^{(i)}))} \cong \pi_U^* (\Theta_{M_{C/T}^\alpha(d, (r_j^{(i)}))/T \times N(d, (r_j^{(i)}))} \cong \Omega^1_{C \times T}(F_\bullet). $$

Take an affine open covering $C \times T = \bigcup \alpha U$ and a member $v \in H^0(U, \Omega^1_{\pi_U} F_\bullet) = H^1(C \times T, F_\bullet)$, $v$ is given by $\{(u_{\alpha\beta}), \{v_{\alpha\beta}\}\}$, where $\{u_{\alpha\beta}\} \subset C^1(U_a, F^0)$, $\{v_{\alpha\beta}\} \subset C^0(U_a, F^1)$ and

$$ d(u_{\alpha\beta}) = \{u_{\beta\gamma} - u_{\alpha\gamma} + u_{\alpha\beta}\} = 0, \quad \nabla^1 \{v_{\alpha\beta}\} = \{v_{\beta} - v_{\alpha}\} = d(v_{\alpha}). $$

We define a pairing

$$ \omega_U : H^1(C \times T, F_\bullet) \times H^1(C \times T, F_\bullet) \to H^2(C \times T, \Omega^\bullet_{C \times T U/U}) \cong H^0(U, O_U) $$

by

$$ \omega_U(\{(u_{\alpha\beta}), \{v_{\alpha\beta}\}\}, \{(u'_{\alpha\beta}), \{v'_{\alpha\beta}\}\}) := \{(\text{Tr}(u_{\alpha\beta} \circ u'_{\beta\gamma}), -\text{Tr}(u_{\alpha\beta} \circ v'_{\beta}) - \text{Tr}(v_{\alpha} \circ u'_{\alpha\beta})\}). $$

By definition, we can easily see that $\omega_U$ descends to a pairing

$$ \omega : \Theta_{M_{C/T}^\alpha(d, (r_j^{(i)}))/T \times N(d, (r_j^{(i)}))} \times \Theta_{M_{C/T}^\alpha(d, (r_j^{(i)}))/T \times N(d, (r_j^{(i)}))} \to \Omega_{M_{C/T}^\alpha(d, (r_j^{(i)}))}. $$

Take any $C$-valued point $y = (E, \nabla, \{l_j^{(i)}\}) \in M_{C/T}^\alpha(d, (r_j^{(i)}))(C)$, over $(x, \nu) \in T \times N(d, (r_j^{(i)}))$. Then a tangent vector $v \in \text{Hom} \Theta_{M_{C/T}^\alpha(d, (r_j^{(i)}))/T \times N(d, (r_j^{(i)}))}(y)$ corresponds to a $C[t]/(t^2)$-valued point $(E^x, \nabla^x, \{(l_j^{(i)})(x)\}) \in M_{C/T}^\alpha(d, (r_j^{(i)}))(x, U)$ such that $(E^x, \nabla^x, \{(l_j^{(i)})(x)\}) \subset C[t]/(t^2)$ such that $(E^x, \nabla^x, \{(l_j^{(i)})(x)\}) \subset C[t]/(t^2)$. We can check that $\omega(v, v)$ is nothing but the obstruction class for the lifting of $(E^x, \nabla^x, \{(l_j^{(i)})(x)\})$ to a member of $M_{C/T}^\alpha(d, (r_j^{(i)}))(x, U)$.

Since $M_{C/T}^\alpha(d, (r_j^{(i)}))(x, U)$ is smooth, we have $\omega(v, v) = 0$. Thus $\omega$ is skew symmetric.

Let

$$ \xi : \Theta_{M_{C/T}^\alpha(d, (r_j^{(i)}))/T \times N(d, (r_j^{(i)}))} \to \Theta^\vee_{M_{C/T}^\alpha(d, (r_j^{(i)}))/T \times N(d, (r_j^{(i)}))} $$

be the homomorphism induced by $\omega$. For any $C$-valued point $y \in M_{C/T}^\alpha(d, (r_j^{(i)}))(C)$

$$ \xi(y) : H^1(F_\bullet(y)) = \Theta_{M_{C/T}^\alpha(d, (r_j^{(i)}))/T \times N(d, (r_j^{(i)}))}(y) \to \Theta_{M_{C/T}^\alpha(d, (r_j^{(i)}))/T \times N(d, (r_j^{(i)}))}^\vee(y) = H^1(F_\bullet(y))^\vee $$

induces an exact commutative diagram

$$ \begin{array}{cccccc}
H^0(F^0(y)) & \longrightarrow & H^0(F^1(y)) & \longrightarrow & H^1(F_\bullet(y)) & \longrightarrow & H^1(F^0(y)) \\
\downarrow b_1 & & \downarrow b_2 & & \downarrow \xi(y) & & \downarrow b_3 \\
H^1(F^1(y))^\vee & \longrightarrow & H^1(F^0(y))^\vee & \longrightarrow & H^1(F_\bullet(y))^\vee & \longrightarrow & H^0(F^0(y))^\vee,
\end{array} $$

where $b_1, b_2, b_3, b_4$ are isomorphisms induced by $F^0(y) \cong F^1(y)^\vee \otimes \Omega_{C_y}^1$, $F^1(y) \cong F^0(y)^\vee \otimes \Omega_{C_y}^1$ and Serre duality. Thus $\xi(y)$ becomes an isomorphism by the five lemma.

Now we will prove that $\omega$ is d-closed. As is explained in section 2, we have a smooth projective surjective morphism $p : M_{C/T}^\alpha(d, (r_j^{(i)}))(x, U) \to M_{C/T}^\alpha(d, (r_j^{(i)}))(x, U)$ and a closed immersion $\iota : M_{C/T}^\alpha(d, (r_j^{(i)}))(x, U) \hookrightarrow \ldots$. 

Take any closed point \( y \in M_{0,T}(\tilde{r},r,d)_{(x,\nu)} \). Then there is a subscheme \( U \subset M_{0,T}(\tilde{r},r,d)_{(x,\nu)} \) such that \( p|_U: U \to M_{0,T}(\tilde{r},r,d)_{(x,\nu)} \) is étale and \( y \in p(U) \). We can take a closed point \( y' \in U \) such that \( p(y') = y \). Then \( y' \) corresponds to a member \( (E,\nabla,\{l_{ij}^{(i)}\}) \in M_{0,T}(\tilde{r},r,d)_{(x,\nu)} \) and \( y' \) corresponds to a member \( (E,\nabla,\{l_{ij}^{(i)}\},\{V_{ij}^{(i)}\}) \). Take tangent vectors \( v, w \in \Theta_U(y') \). Since \( \Theta_U(y') \cong \Theta_M^{\alpha}(\tilde{r},r,d)_{(x,\nu)}(y) \), we can regard \( v, w \) as elements of \( H^1(\mathcal{F}^*(y)) \). Put

\[
\begin{align*}
\tilde{F}^0 := \{ & a \in \mathcal{End}(E) \mid \text{for the induced morphism } a_{ij}^{(i)} : l_{ij}^{(i)}/l_{ij+1}^{(i)} \to l_{ij+1}^{(i)}/l_{ij+2}^{(i)} \text{ and we have } (a_{ij}^{(i)} \circ \text{id})(V_{ij}^{(i)}) \subset V_{ij+1}^{(i)} \text{ for any } i, j, k \\
\tilde{F}^1 := \{ & b \in \mathcal{End}(E) \otimes \mathcal{Omega}_C^1(D) \mid \text{for the induced morphism } b_{ij}^{(i)} : l_{ij}^{(i)}/l_{ij+1}^{(i)} \to l_{ij+1}^{(i)}/l_{ij+2}^{(i)} \text{ and we have } b_{ij}^{(i)}(V_{ij}^{(i)}) \subset V_{ij+1}^{(i)} \text{ for any } i, j, k \\
\tilde{\nabla}^1 : & \tilde{F}^0 \ni a \mapsto \nabla \circ a - a \circ \nabla \in \tilde{F}^1.
\end{align*}
\]

We have a canonical commutative diagram

\[
\begin{array}{ccc}
F^0(y) & \xrightarrow{\nabla^1} & \tilde{F}^0 \\
\downarrow & & \downarrow \tilde{\nabla}^1 \\
F^1(y) & \longrightarrow & \tilde{F}^1.
\end{array}
\]

Then we have

\[
\begin{align*}
\Theta_U(y') & \cong H^1(\mathcal{F}^*(y)), \\
\Theta_{M_{0,T}(\tilde{r},r,d)_{(x,\nu)}}(y') & \cong H^1(\tilde{F}^0 \to F^1(y)), \\
\Theta_{M_{0,T}(\tilde{r},r,d)_{(x,\nu)}}(y') & \cong H^1(\tilde{F}^0 \to \tilde{F}^1),
\end{align*}
\]

and canonical homomorphisms

\[
\begin{align*}
\Theta_{M_{0,T}(\tilde{r},r,d)_{(x,\nu)}}(y') & \cong H^1(\tilde{F}^0 \to F^1(y)) \xrightarrow{\rho} H^1(\mathcal{F}^*(y)) \cong \Theta_{M_{0,T}(\tilde{r},r,d)_{(x,\nu)}}(y).
\end{align*}
\]

There is a canonical symplectic form \( \tilde{\omega} \) on \( M_{0,T}(\tilde{r},r,d)_{(x,\nu)} \). There exists a splitting \( s: H^1(\mathcal{F}^*(y)) \to H^1(\tilde{F}^0 \to \tilde{F}^1) \) of \( p_*: H^1(\tilde{F}^0 \to F^1(y)) \to H^1(\mathcal{F}^*(y)) \) determined by \( U \). Take an affine open covering \( C_x = \bigcup U_a \). The tangent vectors \( v, w \) can be represented by \( (\{a_{a\beta}\},\{b_a\}) \) and \( (\{a'_{a\beta}\},\{b'_a\}) \), respectively, where \( \{a_{a\beta}\},\{a'_{a\beta}\} \subset C^1(\{U_a\},\mathcal{F}^0(y)) \) and \( \{b_a\},\{b'_a\} \subset C^0(\{U_a\},F^1(y)) \). Replacing \( a_{a\beta},a'_{a\beta},b_a,b'_a \), we may have that \( s(v) \) and \( s(w) \) can be represented by \( (\{a_{a\beta}\},\{b_a\}) \) and \( (\{a'_{a\beta}\},\{b'_a\}) \), respectively with \( \{a_{a\beta}\},\{a'_{a\beta}\} \subset C^1(\{U_a\},F^0) \). Then we have

\[
\tilde{\omega}(\iota_+(s(v)),\iota_+(s(w))) = \left( \{\text{Tr}(a_{a\beta} \circ a'_{a\beta})\}, -\{\text{Tr}(a_{a\beta} \circ b'_a) - \text{Tr}(b_a \circ a'_{a\beta})\} \right) = \omega(v,w),
\]

which means that \( \tilde{\omega}|_U = (p|_U)^*(\omega) \). Since \( \tilde{\omega} \) is \( d \)-closed, \( (p|_U)^*(\omega) \) is also \( d \)-closed. Thus \( \omega \) is \( d \)-closed, because \( p|_U: U \to M_{0,T}(\tilde{r},r,d)_{(x,\nu)} \) is étale.

4. Isomonodromic Deformation

Let \( T \) be an algebraic scheme over \( \mathbb{C} \), which is a smooth covering of the moduli stack of \( n \)-pointed smooth projective curves of genus \( g \). Take a universal family \( (\tilde{C},\tilde{\nu}) \) over \( T \). For the spectral type \( (r_{ij}^{(i)}) \), assume that we can take a parabolic weight \( \alpha \) such that \( \alpha \)-stable \( \Leftrightarrow \alpha \)-semistable. We choose \( \alpha' \) as in section 2. As is stated in [3], Proposition 8.1, there is an algebraic splitting

\[
D: \pi^*\Theta(T) \to \Theta_{M_{0,T}'(\tilde{r},r,d)}
\]

of the canonical surjection \( \pi_*: \Theta_{M_{0,T}'(\tilde{r},r,d)} \to \pi^*\Theta(T) \), where \( \pi: M_{0,T}(\tilde{r},r,d) \to T \) is the structure morphism. By the construction of \( D \) in [3], Proposition 8.1, we can see that the image of \( D|_{\tilde{M}_{0,T}'(\tilde{r},r,d)} \) is
contained in $\Theta_{\tilde{M}_{C/T}(d,(r_j^{(i)})]} \subset \Theta_{M_{C/T}(r,d)}|\tilde{M}_{C/T}(d,(r_j^{(i)})].$ Since $D(\pi^*(\Theta_T)) \subset \Theta_{M_{C/T}(r,d)}$ satisfies the integrability condition, $D|_{\tilde{M}_{C/T}(d,(r_j^{(i)})]}((\pi|_{\tilde{M}_{C/T}(d,(r_j^{(i)})])^*(\Theta_T)) \subset \Theta_{\tilde{M}_{C/T}(d,(r_j^{(i)})]}$ also satisfies the integrability condition. Consider the projective surjective morphism
\[
p: \tilde{M}_{C/T}(d,(r_j^{(i)})] \to M_{C/T}(d,(r_j^{(i)})]
\]
as in section 2. Note that the geometric fibers of $p$ are irreducible. Then we obtain a homomorphism
\[
D': (\pi')^*(\Theta_T) \xrightarrow{\sim} p_*(\pi^*(\Theta_T)) \to p_*(\Theta_{\tilde{M}_{C/T}(d,(r_j^{(i)})]} \to p_*(\pi^*(\Theta_{M_{C/T}(d,(r_j^{(i)})])) \xrightarrow{\sim} \Theta_{M_{C/T}(d,(r_j^{(i)})]},
\]
which is a splitting of the canonical homomorphism $\pi': \Theta_{M_{C/T}(d,(r_j^{(i)})]} \to (\pi')^*(\Theta_T),$ where $\pi': M_{C/T}(d,(r_j^{(i)})] \to T$ is the structure morphism. Since $D|_{\tilde{M}_{C/T}(d,(r_j^{(i)})]}((\pi|_{\tilde{M}_{C/T}(d,(r_j^{(i)})])^*(\Theta_T)) \subset \Theta_{\tilde{M}_{C/T}(d,(r_j^{(i)})]}$ satisfies the integrability condition, $D'((\pi')^*(\Theta_T)) \subset \Theta_{\tilde{M}_{C/T}(d,(r_j^{(i)})]}$ also satisfies the integrability condition. The corresponding foliation $F_{M_{C/T}(d,(r_j^{(i)})]}$ is nothing but the isomonodromic deformation.

**Theorem 4.1.** Assume that $rn - 2r - 2 > 0$ if $g = 0$, $n > 1$ if $g = 1$ and $n > 0$ if $g \geq 2$. Moreover, assume that we can take $\alpha$ so that $\alpha$-stable $\iff \alpha$-semistable. Then the foliation $F_{M_{C/T}(d,(r_j^{(i)})]}$ satisfies the geometric Painlevé property, namely for any path $\gamma: [0,1] \to T$ and for any point $x \in M_{C/T}(d,(r_j^{(i)})]$ with $\pi'(x) = \gamma(0),$ there is a unique path $\tilde{\gamma}: [0,1] \to M_{C/T}(d,(r_j^{(i)})]$ which lies in a leaf of $F_{M_{C/T}(d,(r_j^{(i)})]}$ such that $\pi' \circ \tilde{\gamma} = \gamma$ and that $\tilde{\gamma}(0) = x.$

**Proof.** Take any path $\gamma: [0,1] \to T$ and a point $x \in M_{C/T}(d,(r_j^{(i)})]$ such that $\pi'(x) = \gamma(0).$ Since $p: \tilde{M}_{C/T}(d,(r_j^{(i)})] \to M_{C/T}(d,(r_j^{(i)})]$ is surjective, there is a point $\tilde{x} \in M_{C/T}(d,(r_j^{(i)})]$ such that $p(\tilde{x}) = x.$ By the geometric Painlevé property stated in [4, Theorem 2.3], there is a unique path $\gamma': [0,1] \to M_{C/T}(r,d)$ such that $\gamma'(0) = \tilde{x},$ $\pi(\tilde{x}) = \gamma(0)$ and that the image of $\gamma'$ lies in a leaf of the foliation determined by $D(\pi^*(\Theta_T)) \subset \Theta_{M_{C/T}(r,d)}.$ By construction, the image of $\gamma'$ in fact lies in $\tilde{M}_{C/T}(d,(r_j^{(i)})].$ So the path $p \circ \gamma'$ satisfies the desired condition.
