Single index regression models in the presence of censoring depending on the covariates

Olivier LOPEZ\textsuperscript{1} \hspace{1cm} Valentin PATILEA\textsuperscript{2} \hspace{1cm} Ingrid VAN KEILEGOM\textsuperscript{3}

November 29, 2011

Abstract

Consider a random vector \((X', Y)'\), where \(X\) is \(d\)-dimensional and \(Y\) is one-dimensional. We assume that \(Y\) is subject to random right censoring. The aim of this paper is twofold. First we propose a new estimator of the joint distribution of \((X', Y)'\). This estimator overcomes the common curse-of-dimensionality problem, by using a new dimension reduction technique. Second we assume that the relation between \(X\) and \(Y\) is given by a single index model, and propose a new estimator of the parameters in this model. The asymptotic properties of all proposed estimators are obtained.

Key words: Curse-of-dimensionality; Dimension reduction; Multivariate distribution; Right censoring; Semiparametric regression; Survival analysis.

Short title: Censored single index regression

1 Introduction and model

Consider a random vector \((X', Y')'\), where \(X = (X^{(1)}, \ldots, X^{(d)})'\) is \(d\)-dimensional and \(Y\) is one-dimensional. We assume that \(Y\) is subject to random right censoring, i.e. instead of observing \((X', Y')'\), we observe the triplet \((X', T, \delta)'\), where \(T = Y \land C\), \(\delta = I(Y \leq C)\), and the random variable \(C\) is the censoring variable. Typically, \(Y\) is (a transformation of) the survival time (whose range can span the whole real line), and \(X\) is a vector of characteristics. The data consist of \(n\) i.i.d. replications \((X'_i, T_i, \delta_i)'\) of \((X', T, \delta)'\).

Under this setting, the purpose of this paper is twofold. First, we propose a new estimator of the joint distribution \(F(x, y) = P(X \leq x, Y \leq y)\) of \(X\) and \(Y\) (where \(X \leq x\) means that \(X^{(j)} \leq x^{(j)}\) for \(j = 1, \ldots, d\)). Second, we assume that the relation between \(X\) and \(Y\) is given by a single index mean regression model (as in e.g. Härdle, Hall and Ichimura, 1993), and we propose new estimators of the parameters under this model. These estimators will be constructed under the following fundamental model assumption on the relation between \(Y\) and \(C\), which we impose throughout this paper:

\((A0)\) There exists a function \(g : \mathbb{R}^d \to \mathbb{R}\), such that:

\[ (i) \text{ } Y \text{ and } C \text{ are independent, conditionally on } g(X) \]

\[ (ii) \ P(Y \leq C|X,Y) = P(Y \leq C|g(X), Y). \]

The function \(g\) will be unknown in general. When \(g\) is known, this assumption has been proposed by Lopez (2007a). The assumption is needed for identifying the model. In the literature on nonparametric censored regression, alternatives to assumption \((A0)\) have been proposed. There are basically two alternatives, which can be regarded as limiting cases of assumption \((A0)\), and in that sense our assumption is a trade-off between these two. The first alternative has been used by e.g. Akritas (1994) and Van Keilegom and Akritas (1999), among many others. They assume that \(Y\) is independent of \(C\), conditionally on \(X\), and propose kernel type estimators of the distribution \(F(x, y)\) under this assumption. This assumption is a particular case of \((A0)\) by taking \(g(X) \equiv X\). Their estimators are however restricted to the case where \(d = 1\). Although they could in principle be extended to higher dimensions, this is not recommended in practice, since they will suffer from the curse-of-dimensionality and higher order kernels will need to be used. The second alternative to assumption \((A0)\) has been proposed by Stute (1993, 1996). He assumes that \(Y\) is independent of \(C\), and that \(P(Y \leq C|X,Y) = P(Y \leq C|Y)\). This is again a particular case of \((A0)\), by taking \(g(X) \equiv 1\). Although his estimator can
be used for any $d \geq 1$, it has the drawback that it assumes that the censoring variable $C$ depends on $X$ in a very particular way. This type of dependence might hold true when the censoring is purely ‘administrative’ (censoring at the end of the study), but when the censoring can be caused by other factors (like death due to another disease, change of treatment, ...), then less restrictive assumptions on the censoring mechanism are required.

Our assumption (A0) balances somewhere in between these two extreme assumptions. By imposing assumption (A0), we propose a new dimension reduction technique, which overcomes the drawbacks of these two classical sets of assumptions, by allowing for $d \geq 1$ without assuming the complete independence between $Y$ and $C$. Note that assumption (A0) holds in the particular case where $L(C|X,Y) = L(C|g(X))$. By assuming that the censoring variable depends on $X$ only through a one-dimensional variable $g(X)$, we avoid the curse-of-dimensionality problems which strike regression approaches where $X$ is multivariate and $Y$ is independent of $C$ conditionally on $X$, and at the same time the dependence of $C$ on $X$ is not too restrictive. A related dimension reduction model assumption for the censoring time has been considered in Section 4 of Li, Wang, and Chen (1999).

In some cases, the function $g$ will be known exactly from some a priori information. For example, we might know that the censoring only depends on one component of $X$, for example $g(X) = X^{(1)}$. Lopez (2007a) proposed an estimator of the joint distribution $F(x,y)$ when $g$ is supposed to be known. However, in many other cases, $g$ will be unknown and needs to be estimated. Throughout this paper, we will assume that

$$g \in \mathcal{G}, \text{ where } \mathcal{G} = \{ x \rightarrow \lambda(\theta, x) : \theta \in \Theta \},$$

where $\lambda$ is a known function, and $\Theta$ is a compact parameter set in $\mathbb{R}^k$. The true (but unknown) value of $\theta$ will be denoted by $\theta_0$.

Throughout the paper, we will assume that we know some root-$n$ consistent estimator $\hat{\theta}$ of $\theta_0$, that satisfies the following:

(C0) The estimator $\hat{\theta}$ satisfies:

$$\hat{\theta} - \theta_0 = \frac{1}{n} \sum_{i=1}^{n} \mu(T_i, \delta_i, X_i) + o_P(n^{-1/2}),$$

with $E[\mu(T, \delta, X)] = 0$ and $E[\mu(T, \delta, X)^2] < \infty$.

Hence, the set $\Theta$ can from now on be taken equal to an arbitrarily small environment of $\theta_0$. 

3
To illustrate the nature of assumptions (A0) and (C0), consider the function \( g(x) = \theta_0'x \), and the case where \( C \) follows a Cox regression model given \( X \), in the sense that the conditional hazard \( h(\cdot | x, y) \) of \( C \) given \( X = x \) and \( Y = y \) satisfies
\[
h(c|x, y) = h_0(c) \exp(\theta_0'x)
\]
for some baseline function \( h_0 \) only depending on \( c \). Note that this model assumption on \( C \) is not unrealistic, since often the censoring variable \( C \) represents itself a lifetime, like the time until a patient dies from a disease other than the disease under study. Under this model, we clearly have \( \mathcal{L}(C|X,Y) = \mathcal{L}(C|\theta_0'X) \), and the estimator \( \hat{\theta} \) proposed by Andersen and Gill (1982) satisfies condition (C0), with
\[
\mu(t, \delta, x) = \Sigma^{-1} \left( (1 - \delta) \phi(x, t) - \int \phi(x, u) \mathbf{1}_{t > u} [1 - G(u - |x|)^{-1}] dG(u|x) \right),
\]
where the matrix \( \Sigma \) is defined by condition D in Andersen and Gill (1982),
\[
\phi(x, t) = x - \frac{E[X e^{\theta_0'X} (1 - H(t|X))]}{E[e^{\theta_0'X} (1 - H(t|X))]},
\]
with \( H(t|x) = \mathbb{P}(T \leq t|X = x) \) and \( G(c|x) = \mathbb{P}(C \leq c|X = x) \). See also Gorgens and Horowitz (1999) for regression models more general than Cox in which \( \mathcal{L}(C|X,Y) = \mathcal{L}(C|\theta_0'X) \). Alternatively, one could also assume that \( C = r(\theta_0'X) + U \), where \( r(\cdot) \) is given, \( E(U) = 0 \), and \( U \) is independent of \( X \) and \( Y \). For the estimation of \( \theta_0 \) and the verification of condition (C0) under this model, see e.g. Akritas and Van Keilegom (2000) and Heuchenne and Van Keilegom (2007).

The purpose of this paper is twofold. The first contribution of this paper consists in proposing and studying a new nonparametric estimator of the joint distribution of \( X \) and \( Y \) under assumption (A0). Under different sets of assumptions on the relation between \( X \), \( Y \) and \( C \), this distribution has been the object of study of many papers in the past. See e.g. Akritas (1994), Stute (1993, 1996), Van Keilegom and Akritas (1999), among others. As mentioned before, assumption (A0) allows to avoid the curse-of-dimensionality problem present in some of these contributions, and the heavy assumptions on the relation between \( C \) and \( X \), which are present in many others.

The second contribution of this paper is the estimation of a semiparametric single index regression model for the censored response \( Y \) given \( X \) under assumption (A0). The proposed estimator is based on a two-step procedure, in which first a preliminary (consistent) estimator is obtained, which is then used to obtain in a second step a more accurate estimator. Both steps heavily rely on the estimator of \( F(x, y) \) studied before.
Note that in this second contribution two dimension reduction techniques are used: the first one comes from assumption (A0), which is concerned with the relation between $Y$ and $C$, and the second one comes from the single index model, which is making an hypothesis on the relation between $Y$ and $X$.

Single index regression models are now a common semiparametric multivariate explanatory approach, see for instance Delecroix, Hristache and Patilea (2006) for a review. However, the literature on single index models with a censored response variable is rather poor. To the best of our knowledge, the only contribution that allows for a general relationship between the censoring variable and the covariates is Li, Wang and Chen (1999) and it is based on sliced inverse regression (SIR). However, it is well known that the SIR approach requires a linear conditional expectation condition among the covariates, which may be rather restrictive in some applications, see equation (2.3) in Li, Wang and Chen (1999).

Lopez (2008) proposed a semiparametric least squares estimator for the single index regression in the particular case where $g(X) \equiv 1$ in assumption (A0). A similar procedure was introduced by Wang et al. (2007) under the stronger assumption that $C$ is independent of $(X',Y')$. See also Lu and Cheng (2007). Lu et Burke (2005) used the same more restrictive condition to define an average derivative estimator of the index. It is worthwhile to notice that these three contributions involve a Kaplan-Meier estimate of the censoring distribution, while in general assumption (A0) requires a nonparametric estimate of the conditional distribution of $C$ given $g(X)$.

This paper is organized as follows. In the next section the estimators of the joint distribution and of the parameters in the single index model are explained in detail. Section 3 is devoted to the presentation of the asymptotic results of the proposed estimators. Finally, Appendix A contains the assumptions under which the results of Section 3 are valid, while Appendix B contains some technical lemmas and the proofs of the main results.

2 The estimators

2.1 Estimation of the distribution $F(x, y)$

We first explain how to estimate the joint distribution $F(x, y)$ of $X$ and $Y$. For an arbitrary value of $\theta$, let

$$G_\theta(t|z) = \mathbb{P}(C \leq t|\lambda(\theta, X) = z),$$

(2.1)
and define

\[ \hat{G}_\theta(t|z) = 1 - \prod_{T_i \leq t} \left( 1 - \frac{w^\theta_m(z)}{\sum_{j=1}^n w^\theta_j(z) 1_{T_j \geq T_i}} \right)^{1-\delta_i}, \]  

(2.2)

where

\[ w^\theta_m(z) = \frac{K \left( \frac{\lambda(\theta, X_i) - z}{a_n} \right)}{\sum_{j=1}^n K \left( \frac{\lambda(\theta, X_j) - z}{a_n} \right)}. \]

Here, \( a_n \) is a bandwidth sequence converging to zero as \( n \) tends to infinity, and \( K \) is a probability density function (kernel). Note that \( \hat{G}_\theta(t|z) \) reduces to the estimator proposed by Beran (1981) when \( \lambda(\theta, X) \) is equal to \( X \).

With at hand the estimator \( \hat{\theta} \) introduced in condition (C0), and the corresponding estimator \( \hat{g}(x) = \lambda(\hat{\theta}, x) \) of \( g(x) \), we now define the following estimator of \( F(x, y) \):

\[ \hat{F}_g(x, y) = \frac{1}{n} \sum_{i=1}^n \frac{\delta_i 1_{T_i \leq y, X_i \leq x}}{1 - \hat{G}_\theta(T_i - |\hat{g}(X_i)|)}. \]  

(2.3)

Note that this estimator is in the same spirit as the estimator proposed by Stute (1993, 1996), but the denominators of the two estimators are different, because of the different sets of underlying assumptions. See also Fan and Gijbels (1994) for a similar weighting scheme in a nonparametric regression framework. Also note that when \( g \) would be known, this estimator equals the estimator proposed and studied in Lopez (2007b).

In Section 3.1 we will study the asymptotic properties of the estimator \( \hat{F}_g(x, y) \).

2.2 Estimation of the single index model

We first need to introduce some notations. For \( \theta \in \Theta \), let \( Z_\theta = \lambda(\theta, X) \), and let \( Z_\theta \subset \mathbb{R} \) be the support of the variable \( Z_\theta \). We assume that \( Z_\theta \) is compact for all \( \theta \in \Theta \). Also, define \( H_\theta(t|z) = \mathbb{P}(T \leq t | Z_\theta = z) \) and let \( \tau_{H_\theta,z} = \inf \{ t : H_\theta(t|z) = 1 \} \).

We assume that the following single index mean regression model is valid: for some \( \beta_0 \in \mathcal{B} \subset \mathbb{R}^d \), with, say, first component \( \beta_0^{(1)} = 1 \),

\[ E[Y \mid X, Y \leq \tau] = E[Y \mid \beta_0 X, Y \leq \tau] = m(\beta_0 X), \]  

(2.4)

where \( m \) is an unknown function, and where \( \tau \) is some fixed truncation point, satisfying

\[ \tau < \inf_{\theta \in \Theta} \inf_{z \in Z_\theta} \tau_{H_\theta,z}. \]

Let \( f(t; \beta) = E[Y | \beta' X = t, Y \leq \tau] \). Then, \( f(\cdot; \beta_0) = m(\cdot) \). Also, let \( \mathcal{B} = \{1\} \times \tilde{B} \), where \( \tilde{B} \) is a compact subset of \( \mathbb{R}^{d-1} \), and denote by \( X \) the support of the covariate vector \( X \), which is a compact subset of \( \mathbb{R}^d \).
The truncation at $\tau$ in model (2.4) is very natural and common in the context of regression with right censored observations, and is caused by the lack of information in the right tail of the conditional distribution of $Y$ given $X$. See e.g. Akritas (1994) and Akritas and Van Keilegom (2000) for similar truncation mechanisms. Note that when $L(Y|X) = L(Y|\beta'_0X)$, i.e. when the whole distribution of $Y$ given $X$ only depends on $X$ via $\beta'_0X$, then model (2.4) is satisfied for any value of $\tau$.

The estimation of $\beta_0$ consists of several steps. We first explain these steps in an informal, intuitive way to outline the main ideas behind the proposed method, and we next work out each of these steps in a rigorous way.

1. Estimate $f(t; \beta)$ using some nonparametric estimator $\hat{f}(t; \beta)$.

2. Construct a preliminary consistent estimator $\beta_n$ of $\beta_0$.

3. Use $\beta_n$ to compute a trimming function. This trimming function avoids technical problems caused by denominators close to zero in the nonparametric estimation of $f(t; \beta)$.

4. Construct a second semi-parametric estimator $\hat{\beta}$ of $\beta_0$ by using the trimming function of the preceding step.

2.2.1 Estimation of $f(t; \beta)$

One possible estimator of $f(t; \beta)$ is

$$\hat{f}(t; \beta) = \frac{\int \tilde{K}(\beta'_0x - t)1_{y \leq \tau}d\hat{F}_\beta(x, y)}{\int \tilde{K}(\beta'_0x - t)1_{y \leq \tau}d\hat{F}_\beta(x, y)}, \quad (2.5)$$

where $h = h_n$ is a second bandwidth sequence, possibly different from the bandwidth $a_n$ used to estimate the joint distribution $F(x, y)$, and where $\tilde{K}$ is a kernel function. However, other estimators may be used, for example $[\hat{F}_\beta(\tau|t)]^{-1}\int 1_{y \leq \tau}d\hat{F}_\beta(y|t)$, where $\hat{F}_\beta(y|t)$ denotes Beran’s (1981) estimator of $P(Y \leq y|\beta'_0X = t)$.

In what follows, we do not specify the choice of estimator of $f(t; \beta)$. Instead we will work with a generic estimator $\hat{f}(t; \beta)$ that satisfies certain conditions that need to be fulfilled in order to obtain the asymptotic normality of $\hat{\beta}$, and we will prove in Section 3.2 that the estimator in (2.5) satisfies these conditions.
2.2.2 Preliminary estimation of $\beta_0$

We assume that we know some set $B$ such that
\[ \inf_{\beta \in B, x \in B} f_{\beta}^*(\beta'x) = c > 0, \]
where the function $f_{\beta}^*$ denotes the density of $\beta'X$, conditionally on $Y \leq \tau$. Define the following preliminary trimming function:
\[ \tilde{J}(x) = 1_{x \in B}. \quad (2.6) \]

Let $M(\beta, f, \tilde{J}) = E[(Y - f(\beta'X; \beta))^2 1_{Y \leq \tau} \tilde{J}(X)]$, and note that this is minimized as a function of $\beta$ when $\beta = \beta_0$. Motivated by this fact, we define the preliminary estimator $\beta_n$ of $\beta_0$ by replacing all unknown quantities in $M(\beta, f, \tilde{J})$ by appropriate estimators, i.e.
\[ \beta_n = \arg\min_{\beta \in B} \int (y - \hat{f}(\beta'x; \beta))^2 1_{y \leq \tau} \hat{J}(x) d\tilde{F}(x, y) \]
\[ = \arg\min_{\beta \in B} M_n(\beta, \hat{f}, \hat{J}). \quad (2.7) \]

Note that other criterion functions can be used, based on $M$ or $L$-estimating functions. We do not consider them here, since their analysis is very similar to the one for the least squares criterion function.

2.2.3 New trimming function

We will now refine the definition of the trimming function, by using the preliminary estimator $\beta_n$. Define
\[ J(x) = 1_{f_{\beta_n}^*(\beta_n'x) > c}, \quad (2.8) \]
so instead of requiring that $f_{\beta}^*(\beta'x) > c$ for all $\beta$, we now only consider $\beta = \beta_n$, which will be satisfied for many more $x$-values, and hence this new function $J(x)$ is trimming much less than the preliminary naive trimming function $\tilde{J}(x)$.

To simplify our discussion, we will directly consider that the true function $f_{\beta_n}^*$ is used in the definition of $J$. In practice, the trimming function can be estimated by $1_{\hat{f}_{\beta_n}^*(\beta_n'x) > c}$, where
\[ \hat{f}_{\beta_n}^*(t) = \frac{1}{nb_n \mathbb{P}(Y \leq \tau)} \sum_{i=1}^n \frac{\delta_i 1_{T_i \leq \tau}}{1 - \tilde{G}(T_i - |\tilde{g}(X_i))} K \left( \frac{\beta_n'X_i - t}{b_n} \right), \]
and where $b_n \to 0$ is a bandwidth parameter. In applications, $c_1 = c \mathbb{P}(Y \leq \tau)$ can be chosen arbitrarily small by the statistician. Considering $f_{\beta_n}^*$ or $\hat{f}_{\beta_n}^*$ does not change anything asymptotically speaking, see the arguments in Delecroix, Hristache, Patilea (2006), see
also Step 0 in the proof of Theorem 3.5 below. By similar arguments, the estimator of \( \beta_0 \) obtained with \( \mathbf{1}_{f_{\beta_0}(\beta'_0x)>c} \) is asymptotically equivalent to the ‘ideal’ estimator obtained with the trimming function

\[
J_0(x) = \mathbf{1}_{f_{\beta_0}(\beta'_0x)>c},
\]

as long as \( \beta_n \) is a consistent estimator of \( \beta_0 \). Let us point out that \( J_0 \) only depends on \( \beta'_0x \) and, in view of equation (A.14) in the proof of Theorem 3.5, this property will be essential for achieving \( \sqrt{n} \)-asymptotic normality of our estimator \( \hat{\beta} \) defined below.

2.2.4 Estimation of \( \beta_0 \)

With at hand this new trimming function, we can now define a new semi-parametric least squares estimator of \( \beta_0 \):

\[
\hat{\beta} = \arg \min_{\beta \in \mathcal{B}_n} \int (y - \hat{f}(\beta'x; \beta))^2 \mathbf{1}_{y \leq \tau} J(x) d\hat{F}_y(x, y)
\]

\[
= \arg \min_{\beta \in \mathcal{B}_n} M_n(\beta, \hat{f}, J),
\]

where \( \mathcal{B}_n \) is a set shrinking to \( \{ \beta_0 \} \), which is computed from the preliminary step. The proof of the asymptotic normality of \( \hat{\beta} \) will be carried out in two steps. We will first show that minimizing \( M_n(\beta, \hat{f}, J) \) is asymptotically equivalent to minimizing \( M_n(\beta, f, J_0) \). This then brings back the minimization problem to a fully parametric one.

3 Asymptotic properties

3.1 Estimation of the distribution \( F(x, y) \)

Let us first introduce a few notations. Denote \( H(t) = \mathbb{P}(T \leq t) \), \( H_\theta(t|z) = \mathbb{P}(T \leq t|Z_\theta = z) \), \( H_{\theta,0}(t|z) = \mathbb{P}(T \leq t, \delta = 0|Z_\theta = z) \), and \( H_{\theta,1}(t|z) = \mathbb{P}(T \leq t, \delta = 1|Z_\theta = z) \). For any function \( L(u) \), let \( \nabla_u L(u) \) (respectively \( \nabla^2_{u,u} L(u) \)) denote the vector (respectively matrix) of partial derivatives of order 1 (respectively order 2) of \( L(u) \) with respect to \( u \). In particular, denote by \( \nabla_\theta G_\theta(t|\lambda(\theta, x)) \) the vector of partial derivatives of the function \( G_\theta(t|\lambda(\theta, x)) \) with respect to all occurrences of \( \theta \). Let us point out that, in general, the vector valued function \( \nabla_\theta G_\theta(t|\lambda(\theta, x)) \) depends on \( x \), and not only on \( \lambda(\theta, x) \). Finally, for any matrix \( A \) of dimensions \( k \times \ell \) (where \( k, \ell \geq 1 \)) we denote \( |A| = \text{trace}(A'A) \)^{1/2}.
We further need to introduce two (intermediate) estimators of $F(x,y)$:

$$
\hat{F}_g(x,y) = \frac{1}{n} \sum_{i=1}^{n} \frac{\delta_i 1_{T_i \leq y, X_i \leq x}}{1 - G_{\theta_0}(T_i - |g(X_i)|)}, \quad (3.1)
$$

$$
\hat{F}_g(x,y) = \frac{1}{n} \sum_{i=1}^{n} \frac{\delta_i 1_{T_i \leq y, X_i \leq x}}{1 - G_{\theta_0}(T_i - |g(X_i)|)}. \quad (3.2)
$$

In the following result we consider integrals of the form $\int \phi(x,y) d\hat{F}_g(x,y)$ with $\phi$ belonging to some class of functions $\mathcal{F}$, and we state that this class of integrals is Glivenko-Cantelli and admits an i.i.d. representation uniformly over all $\phi \in \mathcal{F}$. The proof can be found in Lopez (2007b). For a completely nonparametric estimator of $F(x,y)$ that is not based on model assumption (A0), Sánchez-Sellero, González-Manteiga and Van Keilegom (2005) obtained a similar uniform consistency and convergence result. The assumptions mentioned below can be found in Appendix A.

**Theorem 3.1** i) Under Assumptions 1 and 3, for $a_n \to 0$ and $n a_n \to \infty$, and for a class $\mathcal{F}$ satisfying Condition 1, we have

$$
\sup_{\phi \in \mathcal{F}} \left| \int \phi(x,y) d[\hat{F}_g - F](x,y) \right| \to a.s. 0.
$$

ii) For $Z_i = \lambda(\theta_0, X_i)$, define

$$
M_i(t) = (1 - \delta_i) 1_{T_i \leq t} - \int_{-\infty}^{t} \frac{1_{T_i \geq y} dG_{\theta_0}(y|Z_i)}{1 - G_{\theta_0}(y - |Z_i|)},
$$

which is a continuous time martingale with respect to the natural filtration $\sigma(\{Z_i 1_{T_i \leq t}, T_i 1_{T_i \leq t}, \delta_i 1_{T_i \leq t}, i = 1, ..., n\})$. Under Assumptions 1, 2 and for a class $\mathcal{F}$ satisfying Conditions 2, 3,

$$
\int \phi(x,y) d[\hat{F}_g - \tilde{F}_g](x,y) = \frac{1}{n} \sum_{i=1}^{n} \int \frac{\tilde{\phi}(Z_i, s) dM_i(s)}{[1 - F(s - |Z_i|)][1 - G_{\theta_0}(s|Z_i)]} + R_n(\phi),
$$

where $\sup_{\phi \in \mathcal{F}} |R_n(\phi)| = o_P(n^{-1/2})$, $\tilde{\phi}$ is defined above Condition 3, and $F(s|z) = \mathbb{P}(Y \leq s|Z_{\theta_0} = z)$.

The following Theorem furnishes the behavior of the difference between integrals with respect to $\hat{F}_g$ and integrals with respect to $\tilde{F}_g$. 

10
Theorem 3.2 i) Under Assumptions 1, 3 and 5, for $a_n \to 0$ and $na_n \to \infty$, and for a class $\mathcal{F}$ satisfying Condition 4, we have

$$\sup_{\phi \in \mathcal{F}} \left| \int \phi(x,y) d[\hat{F}_g - \hat{F}_g](x,y) \right| = o_p(1).$$

ii) Under Assumptions 1–3 and 5, for $a_n \to 0$ and $na_n^3 (\log n)^{-1} \to \infty$, and for a class $\mathcal{F}$ whose envelope is as in Condition 4,

$$\int \phi(x,y) d[\hat{F}_g - \hat{F}_g](x,y) = -E \left( \frac{\phi(X,Y)\{\nabla_\theta G_{\theta_0}(Y - |\lambda(\theta_0, X))\}'}{1 - G_{\theta_0}(Y - |g(X))} \right) \frac{1}{n} \sum_{i=1}^n \mu(T_i, \delta_i, X_i) + \tilde{R}_n(\phi),$$

where the function $\mu$ is defined in (C0), and where $\sup_{\phi \in \mathcal{F}} |\tilde{R}_n(\phi)| = o_P(n^{-1/2}).$

3.2 Estimation of the single index model

We now return to the single index model (2.4) and to the estimators $\beta_n$ and $\hat{\beta}$ defined in (2.7) and (2.10). We start with stating the asymptotic consistency of the estimator $\beta_n$. Note that the estimator $\hat{\beta}$ is by construction consistent, since it is defined on a shrinking neighborhood of $\beta_0$.

Theorem 3.3 Let $\hat{J}$ be defined as in (2.6). Under Assumptions 1, 3, 5, 7, and 6–(A.1), and for $a_n \to 0$ and $na_n \to \infty$, we have

$$\sup_{\beta \in B} |M_n(\beta, \hat{f}, \hat{J}) - M(\beta, f, \hat{J})| \to 0,$$

in probability. Consequently, $\beta_n \to \beta_0$ in probability.

The next lemma is an important property in the literature on single index models. In the classical uncensored single index regression model, the property $E[\nabla_\beta f(\beta_0'X; \beta_0) | \beta_0'X] = 0$ plays a major role in proving the asymptotic normality of $M$-estimators. See Delecroix, Hristache and Patilea (2006). The next lemma shows that in our context, where we have to truncate at $\tau$ because of censoring in the data, the analogous truncated version of this property holds true without any further model conditions.

Lemma 3.4 Assume that the derivative $\nabla_\beta f(\beta_0'; \beta_0)$ exists and is bounded. Then, for any $\beta_0$ satisfying condition (2.4),

$$E \left[ \nabla_\beta f(\beta_0'X; \beta_0) 1_{Y \leq \tau} \mid \beta_0'X \right] = 0.$$
Theorem 3.5 Let $\phi(x, y) = (y - f(\beta_0'x; \beta_0))\nabla_\beta f(\beta_0'x; \beta_0)1_{y \leq \tau}J_0(x)$. Under Assumptions (C0)-(C2), we have

$$\hat{\beta} - \hat{\beta}_0 = \Omega^{-1} \left[ \int \phi(x, y) d(F_g(x, y) - F(x, y)) \right.\right.$$  

$$+ \frac{1}{n} \sum_{i=1}^{n} \int \left[ \frac{F \phi(g(X_i), s)dM_i(s)}{[1 - F(s - |g(X_i))][1 - G_{\theta_0}(s|g(X_i))]} \right]$$

$$- E \left( \frac{\phi(X, Y)\{\nabla_\theta G_{\theta_0}(Y - |\lambda(\theta_0, X))\}'}{1 - G_{\theta_0}(Y - |\lambda)} \right) \frac{1}{n} \sum_{i=1}^{n} \mu(T_i, \delta_i, X_i) \right] + o_P(n^{-1/2})$$

$$= \Omega^{-1} \left[ \frac{1}{n} \sum_{i=1}^{n} \eta(T_i, \delta_i, X_i) \right] + o_P(n^{-1/2}),$$

where the function $\mu$ is defined in (C0), and where

$$\Omega = E \left[ 1_{y \leq \tau}J_0(X)\nabla_\beta f(\beta_0'X; \beta_0)\nabla_\beta f(\beta_0'X; \beta_0)' \right].$$

Hence,

$$n^{1/2}(\hat{\beta} - \hat{\beta}_0) \overset{d}{\rightarrow} N \left( 0, \Omega^{-1}E[\eta(T, \delta, X)\eta(T, \delta, X)']\Omega^{-1} \right).$$

If we wish to estimate the asymptotic variance in (3.5), we see that we need to estimate the variance of $\Omega^{-1}\eta$. However, one can estimate consistently $\Omega$ by

$$\hat{\Omega} = \frac{1}{n} \sum_{i=1}^{n} 1_{y \leq \tau}J(X_i)\nabla_\beta \hat{f}(\hat{\beta}'X_i; \hat{\beta})\nabla_\beta \hat{f}(\hat{\beta}'X_i; \hat{\beta}).$$

Similarly, when it comes to estimate the covariance matrix of $\eta$, one can proceed by taking the empirical variance of a random vector $(\hat{\eta}(T_i, \delta_i, X_i))_{1 \leq i \leq n}$, where $\hat{\eta}$ denotes an estimated version of $\eta$ in which we replaced each unknown quantity by its empirical counterpart ($f$ replaced by $\hat{f}$, $\beta_0$ by $\hat{\beta}$, $F$ by $F_g$).

We end this Section with the verification of Assumptions (C0)-(C2) for the estimator $\hat{f}(t; \beta)$ defined in (2.3). Define the (uncomputable) kernel estimator based on $\hat{F}_g$,

$$f^*(t; \beta) = \frac{\int \hat{K}(\frac{y-x}{h})y1_{y \leq \tau}d\hat{F}_g(x, y)}{\int K(\frac{y-x}{h})1_{y \leq \tau}d\hat{F}_g(x, y)}.$$  

(3.4)
The advantage of $\tilde{F}_g$, and hence of $f^*$, is that it is composed of sums of i.i.d. terms. Classical arguments show that $f^*$ satisfies Assumptions $[9]$ to $[11]$. This is shown in Proposition 3.6 below. On the other hand, Proposition 3.7 shows that the difference between $\hat{f}$ and $f^*$ is sufficiently small so that $\hat{f}$ also satisfies these assumptions.

**Proposition 3.6** Assume that

(i) $\tilde{K}$ is a symmetric density function with compact support, and with two continuous derivatives of bounded variation;

(ii) $f(\cdot; \beta_0) \in \mathcal{H}_1^0$ and $\nabla_\beta f(\beta'_0; \beta_0) \in \mathcal{H}_2^0$, with $\mathcal{H}_1^0$ and $\mathcal{H}_2^0$ defined in (A.4) and (A.5);

(iii) $nh^5(\log n)^{-1/2} \to \infty$, and $nh^8 \to 0$.

Then, $f^*$ satisfies Assumptions $[9]$, $[11]$.

**Proposition 3.7** Under the assumptions of Theorem 3.2, we have

$$
\sup_{\beta \in \mathbb{B}, x \in \mathcal{X}} |f^*(\beta' x; \beta) - \hat{f}(\beta' x; \beta)| = O_p((\log n)^{1/2}n^{-1/2}a_n^{-1/2}),
$$

$$
\sup_{\beta \in \mathbb{B}, x \in \mathcal{X}} |\nabla_\beta f^*(\beta' x; \beta) - \nabla_\beta \hat{f}(\beta' x; \beta)| = O_p((\log n)^{1/2}h^{-1}n^{-1/2}a_n^{-1/2}),
$$

$$
\sup_{\beta \in \mathbb{B}, x \in \mathcal{X}} |\nabla_{\beta, \beta} f^*(\beta' x; \beta) - \nabla_{\beta, \beta} \hat{f}(\beta' x; \beta)| = O_p((\log n)^{1/2}h^{-2}n^{-1/2}a_n^{-1/2}),
$$

where $\hat{f}$ is the estimator defined in (2.5). Moreover, $\nabla_{\beta} \hat{f}(\beta'_0 x; \beta_0) = x\hat{m}_1(\beta'_0 x) + \hat{m}_2(\beta'_0 x)$, with, for $j = 1, 2$,

$$
\sup_{x \in \mathcal{X}} |\hat{m}_j(\beta'_0 x) - m^*_j(\beta'_0 x)| = O_p((\log n)^{1/2}h^{-1}n^{-1/2}a_n^{-1/2}),
$$

$$
\sup_{u \in \beta'_0 \mathcal{X}} |\hat{m}_j(u) - m'_j(u)| = O_p((\log n)^{1/2}h^{-2}n^{-1/2}a_n^{-1/2}),
$$

where the functions $m^*_j$ are defined in (A.12), and where $m'$ denotes the derivative of the univariate function $\beta'_0 \mathcal{X} \ni u \to m(u)$.

Notice that $\hat{f}'(u; \beta_0) = \hat{m}_1(u)$ (resp. $f'^*(u; \beta_0) = m^*_1(u)$). Combining Propositions 3.6 and 3.7 shows that $\hat{f}$ satisfies Assumptions $[9]$, $[11]$ provided that $nh^8 \to 0$, $na_nh^4(\log n)^{-1} \to \infty$ and $ha_n^{-1/2}(\log n)^{1/2} \to 0$. In the case where $a_n = n^{-1/4+\delta}$ for some $\delta \in ]0, 1[$, these conditions are satisfied if $nh^{4+\delta}(\log n)^{-1} \to \infty$ and $nh^{8-2\delta}(\log n)^{4-\delta} \to 0$.

## 4 Simulation study

To investigate small sample behaviour of our procedure, we considered to different models to perform a simulation study. In the first model, we consider the regression function

$$
m_1(\beta'_0 x) = \beta'_0 x - 0.5(\beta'_0 x)^2,
$$
Table 1: Comparison of the MSE of the proposed estimator (columns $\hat{\beta}$) with the one based on Kaplan-Meier weights (columns KM) for different proportions of censoring.

| Regression model | Proportion of censoring |
|------------------|-------------------------|
|                  | 15%                     | 30%                     | 50%                     |
|                  | $\hat{\beta}$ | KM | $\hat{\beta}$ | KM | $\hat{\beta}$ | KM |
| $m_1$            | 1.022   | 1.463 | 1.147   | 1.279 | 1.619   | 1.728 |
| $m_2$            | 0.580   | 1.480 | 1.290   | 1.613 | 1.407   | 1.633 |

Table 1: Comparison of the MSE of the proposed estimator (columns $\hat{\beta}$) with the one based on Kaplan-Meier weights (columns KM) for different proportions of censoring.

and in the second

$m_2(\beta_0' x) = \log (1 + 0.5\beta_0' x),$

with $\beta_0 = (1, 0.75, 0.25, -0.5)$. We consider residuals $\varepsilon_i = Y_i - m_j(\beta_0' X_i)$ (for $j = 1, 2$) that are Gaussian variables $\mathcal{N}(0, 1)$ independent from $X_i$. The covariates are composed of 4 independent components, following an uniform distribution on $[0, 1]$.

Concerning the censoring variable, we take $C_i|X_i \sim \mathcal{E}(\lambda \exp \theta_0' X_i)$, where $\theta_0 = (0.1, 0.2, -0.1, 0.3)$, and $\lambda$ is a parameter that allows us to modify the average proportion of censored responses. The parameter $\theta_0$ is estimated through maximizing Cox pseudo-likelihood, since the regression model on $C_i$ is a proportional hazards model.

We consider 10000 replications of this simulation scheme for $n = 200$. For each simulated sample $j$, we compute the resulting estimator $\hat{\beta}^{(j)}$ of $\beta_0$ and compute $\|\hat{\beta}^{(j)} - \beta_0\|_2^2$. We then deduce an estimator of the mean square error (MSE) $E[\|\hat{\beta} - \beta_0\|_2^2]$. We took $a_n = 2$ for the bandwidth involved in Beran’s estimator. Since the procedure is more sensitive to the choice of the second bandwidth $h$, we consider a set of bandwidths $h_j = 0.5 + j0.1$, for $j = 1, \ldots, 10$, and for each sample, we take the bandwidth that gives the lowest value of $M_n$. In Table 1, we compare the MSE of the estimator that we propose to the MSE of an estimator based on Kaplan-Meier weights, that is if we replace Beran’s estimator in our approach by a standard Kaplan-Meier estimator. This alternative estimator is the one defined in Lopez (2009). As for our approach, this estimator puts more weights to the largest uncensored observations caused by censoring. Nevertheless this alternative procedure is not adapted to Assumption (A0) that we use in the present framework. Therefore, the estimator of Lopez (2009) is expected to fail in this simulation setting.

As expected, our estimator based on conditional Kaplan-Meier weighting outperforms the estimator of Lopez (2009) in the different situations we consider. It is also natural to observe that the MSE of our estimator $\hat{\beta}$ decreases when the proportion of censoring
Appendix A : Assumptions and conditions

We split the assumptions in three parts, namely those required for the estimation of $F(x, y)$, the estimation of $\beta_0$, and the estimation of $f(\cdot; \beta)$.

Assumptions needed for the estimation of $F(x, y)$. The asymptotic results related to the estimator $\tilde{F}_g(x, y)$ will be valid under the following assumptions and conditions.

**Assumption 1** The distribution $\mathbb{P}(Z_0 \leq z)$ has three uniformly bounded derivatives for $z \in Z_0$ and $\theta \in \Theta$, and the densities $f_{Z_0}(z)$ satisfy $\inf_{\theta \in \Theta} \inf_{z \in Z_0} f_{Z_0}(z) > 0$.

For any function $J(t \mid z)$ we will denote by $J_c(t \mid z)$ the continuous part, and $J_d(t \mid z) = J(t \mid z) - J_c(t \mid z)$. Assumption 2 below has been introduced by Du and Akritas (2002) to obtain their asymptotic i.i.d. representation of the conditional Kaplan-Meier estimator.

**Assumption 2** (i) Let $L(y \mid z)$ denote $H_{\theta_0}(y \mid z)$ or $H_{\theta_0,0}(y \mid z)$. Then, $\nabla_z L(y \mid z)$ and $\nabla^2_{z,z} L(y \mid z)$ exist, are continuous with respect to $z$, and are uniformly bounded as functions of $(z, y)$.

(ii) For some positive nondecreasing bounded (on $[-\infty; \tau]$) functions $L_1$, $L_2$, $L_3$, we have, for all $z \in Z_{\theta_0}$,

$$|H_{\theta_0,c}(t_1 \mid z) - H_{\theta_0,c}(t_2 \mid z)| \leq |L_1(t_1) - L_1(t_2)|,$$

$$|\nabla_z H_{\theta_0,c}(t_1 \mid z) - \nabla_z H_{\theta_0,c}(t_2 \mid z)| \leq |L_2(t_1) - L_2(t_2)|,$$

$$|\nabla^2_{z,z} H_{\theta_0,0,c}(t_1 \mid z) - \nabla^2_{z,z} H_{\theta_0,0,c}(t_2 \mid z)| \leq |L_3(t_1) - L_3(t_2)|,$$

the last two assumptions implying the same kind for $\nabla_z H_{1c}$.

(iii) The jumps of $F_g(\cdot \mid z)$ and $G_{\theta_0}(\cdot \mid z)$ are the same for all $z \in Z_{\theta_0}$. Let $(d_1, d_2, \ldots)$ be the atoms of $G$.

(iv) $F_g(\cdot \mid z)$ and $G_{\theta_0}(\cdot \mid z)$ have two derivatives with respect to $z$, with the first derivatives uniformly bounded (on $[-\infty; \tau]$). The variation of the functions $\nabla_z F_g(\cdot \mid z)$ and $\nabla^2_{z,z} F_g(\cdot \mid z)$ on $[-\infty; \tau]$ is bounded by a constant not depending on $z$. 

15
(v) For all \( d_i \), define
\[
    s_i = \sup_{z \in \mathcal{Z}_0} |F_y(d_i - | z) - F_y(d_i | z)|,
\]
\[
    s'_i = \sup_{z \in \mathcal{Z}_0} |\nabla_z F_y(d_i - | z) - \nabla_z F_y(d_i | z)|,
\]
\[
    r_i = \sup_{z \in \mathcal{Z}_0} |G_{\theta_0}(d_i - | z) - G_{\theta_0}(d_i | z)|,
\]
\[
    r'_i = \sup_{z \in \mathcal{Z}_0} |\nabla_z G_{\theta_0}(d_i - | z) - \nabla_z G_{\theta_0}(d_i | z)|.
\]

Then, \( \sum_{d_i \leq \tau}(s_i + s'_i + r_i + r'_i) < \infty \).

**Assumption 3** The kernel \( K \) is a symmetric probability density function with compact support, and \( K \) has bounded second derivative.

**Assumption 4** The bandwidth \( a_n \) satisfies \((\log n)n^{-1}a_n^{-3} \to 0 \) and \( na_n^4 \to 0 \).

**Assumption 5** The function \((x, t, \theta) \mapsto G_0(t|\lambda(\theta, x)) \) is differentiable with respect to \( \theta \), and the vector \( \nabla_\theta G_0(t|\lambda(\theta, x)) \) is uniformly bounded in \((x, t, \theta)\).

The class of functions \( \mathcal{F} \) considered in Section 3.1 should satisfy the following conditions, which are taken over from Lopez (2007b). The conditions make use of concepts from the context of empirical processes, which can be found e.g. in Van der Vaart and Wellner (1996).

**Condition 1** Let \( p_0(x, y, c) = 1_{y \leq c}[1 - G_{\theta_0}(y - |g(x)|)]^{-1} \). The class \( p_0 \mathcal{F} \) is \( \mathbb{P}(X,Y,C) \)-Glivenko-Cantelli, and has an integrable envelope \( \Phi_0 \) satisfying \( \Phi_0(x, y, c) = 0 \) for \( y > \tau \).

**Condition 2** The covering number \( N(\varepsilon, \mathcal{F}, L^2(\mathbb{P}(X,Y))) \) is bounded by \( A\varepsilon^{-V} \) for \( \varepsilon > 0 \) and for some \( A, V > 0 \), and \( \mathcal{F} \) has a square integrable envelope \( \Phi \) satisfying \( \Phi(x, y) = 0 \) for \( y > \tau \).

Let \( Z = Z_{\theta_0} = g(X) \), let \( F_z(x, y) = \mathbb{P}(X \leq x, Y \leq y|Z = z) \), and for any function \( \phi(x, y) \), define \( \tilde{\phi}(z, s) = \int 1_{s \leq y}\phi(x, y)dF_z(x, y) \). Let \( \mathcal{Z}_{\theta_0, \eta} \) be the set of all points at a distance at least \( \eta > 0 \) from the complementary of \( \mathcal{Z}_{\theta_0} \).

**Condition 3** For all \( \phi \in \mathcal{F} \), \( \tilde{\phi} \) is twice differentiable with respect to \( z \), and
\[
    \sup_{s \leq \tau, z \in \mathcal{Z}_{\theta_0, \eta}} \{|\nabla_z \tilde{\phi}(z, s)| + |\nabla_z \tilde{\phi}(z, s)|\} \leq M < \infty,
\]
for some constant \( M \) not depending on \( \phi \). Moreover, \( \tilde{\Phi} \) is bounded on \( \mathcal{Z}_{\theta_0, \eta} \times [-\infty; \tau] \), and has bounded partial derivatives with respect to \( z \), where \( \Phi \) is the envelope function of Condition 2.
The reason for introducing the set $\mathcal{Z}_{\theta_0,\eta}$ is to prevent us from boundary effects coming from kernel estimators. See Lopez (2007b) for a detailed discussion on this issue.

**Assumptions needed for the estimation of $\beta_0$.** We next state the additional assumptions needed for the asymptotic results concerning the estimation of the parameters in the single index model.

**Assumption 6** There exist $0 < c_0 < c_1 < \infty$ and $\eta > 0$ such that, for each $c \in [c_0, c_1]$ and $x \in \mathcal{X}$,

$$1_{f_{\beta_0}(\beta_0'x) > c} = 1 \implies g(x) \in \mathcal{Z}_{\theta_0,\eta}.$$  

Moreover, assume that

$$|f_{\beta_1}(\beta_1'x) - f_{\beta_2}(\beta_2'x)| \leq C\|\beta_1 - \beta_2\|^\alpha,$$

for some positive constant $C$ and some $\alpha > 0$.

**Assumption 7** (i) $E(|Y|^3) < \infty$;  
(ii) $E[\{|f(\beta'X; \beta) - f(\beta_0'X; \beta_0)|^2 1_{Y \leq r}\}] = 0 \implies \beta = \beta_0$;  
(iii) $\beta_0 = (1, \beta_0')'$ with $\beta_0$ an interior point of $\mathcal{B}$;  
(iv) The class $\{(x, y) \rightarrow f(\beta'x; \beta)1_{y \leq r} : \beta \in \mathcal{B}\}$ satisfies Condition 2 for a continuous integrable envelope $\Psi$.

**Assumption 8** The classes $\{x \rightarrow \nabla_\beta f(\beta'x; \beta) : \beta \in \mathcal{B}\}$ and $\{x \rightarrow \nabla^2_\beta f(\beta'x; \beta) : \beta \in \mathcal{B}\}$ are VC-classes of continuous functions for a uniformly bounded envelope.

**Assumptions needed for the estimation of $f(\cdot; \beta)$.** The last group of assumptions is required for the generic estimator $\hat{f}(\cdot; \beta)$. They are verified in Section 3.2 for the estimator defined in (2.8).

**Assumption 9** For all $c > 0$,

$$\sup_{\beta \in \mathcal{B}, x \in \mathcal{X}} |\hat{f}(\beta'x; \beta) - f(\beta'x; \beta)|1_{f_\beta(\beta'x) > c} = o_P(1), \quad (A.1)$$

$$\sup_{\beta \in \mathcal{B}, x \in \mathcal{X}} |\nabla_\beta \hat{f}(\beta'x; \beta) - \nabla_\beta f(\beta'x; \beta)|1_{f_\beta(\beta'x) > c} = o_P(1), \quad (A.2)$$

$$\sup_{\beta \in \mathcal{B}, x \in \mathcal{X}} |\nabla^2_{\beta,\beta} \hat{f}(\beta'x; \beta) - \nabla^2_{\beta,\beta} f(\beta'x; \beta)|1_{f_\beta(\beta'x) > c} = o_P(1). \quad (A.3)$$

**Assumption 10** There exist Donsker classes $\mathcal{H}_1$ and $\mathcal{H}_2$ such that $f(\cdot; \beta_0) \in \mathcal{H}_1$ and $\nabla_\beta f(\beta_0'; \beta_0) \in \mathcal{H}_2$, and such that with probability tending to one, $\hat{f}(\cdot; \beta_0) \in \mathcal{H}_1$ and $\nabla_\beta \hat{f}(\beta_0'; \beta_0) \in \mathcal{H}_2$.  

17
Typical examples of such kind of Donsker classes are classes of regular functions. Let $\mathcal{T} = \{ \beta'_0 x : x \in \mathcal{X} \} \subset \mathbb{R}$ and let $C^1_\ell(T,M) = \{ h : T \mapsto \mathbb{R}^\ell : \sup_{t \in T} \{|h(t)| + |h'(t)|\} \leq M \}$ for $\ell \geq 1$ and for some $M < \infty$. Define
\[ H^0_0 = C^1_1(T,M), \quad (A.4) \]
\[ H^0_2 = \{ h : \mathcal{X} \mapsto \mathbb{R}^d : x \mapsto xh_1(\beta'_0 x) + h_2(\beta'_0 x) : h_1 \in C^1_1(T,M), h_2 \in C^1_d(T,M) \}, \quad (A.5) \]
The class $H^0_2$ is a Donsker class, which follows from stability properties of Donsker classes (see e.g. Examples 2.10.7 and 2.10.10 in Van der Vaart and Wellner (1996)).

**Assumption 11** For all $c > 0$,
\[
\sup_{x \in \mathcal{X}} |\hat{f}(\beta'_0 x; \beta_0) - f(\beta'_0 x; \beta_0)| 1_{f^\beta_0(\beta'_0 x) > c} = O_P(\varepsilon_n),
\]
\[
\sup_{x \in \mathcal{X}} |\nabla_{\beta} \hat{f}(\beta'_0 x; \beta_0) - \nabla_{\beta} f(\beta'_0 x; \beta_0)| 1_{f^\beta_0(\beta'_0 x) > c} = O_P(\varepsilon'_n),
\]
where $\varepsilon_n$ and $\varepsilon'_n$ satisfy $\varepsilon_n\varepsilon'_n = o(n^{-1/2})$, $a_n^{-1/2}(\log n)^{1/2}\varepsilon_n \to 0$ and $a_n^{-1/2}(\log n)^{1/2}\varepsilon'_n \to 0$.

**Appendix B : Technical lemmas and proofs**

We start this Appendix with two technical lemmas, needed in the proofs of the main results. The first technical lemma gives a concentration inequality for the convergence rate of semi-parametric estimators.

Let $b_n$ be a sequence of real numbers tending to zero, and let $\{ \zeta_\alpha : \alpha \in \mathcal{A} \}$ be a family of uniformly bounded functions, where $\mathcal{A}$ is a compact subset of $\mathbb{R}^p$ (with $p \geq 1$). Consider the class of functions
\[
\mathcal{G} = \left\{ (u, z, t, \delta) \mapsto g_{\alpha,x,v}(u, z, t, \delta) = K^0 \left( \frac{\psi(\alpha, u) - \psi(\alpha, x)}{b_n} \right) \zeta_\alpha(x, u, z, t, \delta) 1_{t \leq v} : \alpha \in \mathcal{A}, x \in \mathcal{X}, v \in \mathbb{R} \right\}, \quad (A.6)
\]
where $K^0$, $\psi$ and $\xi$ are fixed functions, $\mathcal{X} \subset \mathbb{R}^d$ is a compact set, and $t \in \mathbb{R}$, and consider the process (in $\alpha$, $x$ and $v$)
\[
\nu_n(g_{\alpha,x,v}) = \sum_{i=1}^n (g_{\alpha,x,v}(X_i, Z_i, T_i, \delta_i) - E[g_{\alpha,x,v}(X, Z, T, \delta)]).
\]
Typically, $K^0$ denotes either a kernel or its derivative of order 1 or 2.
Lemma A.1 Assume that the class of functions
\[
\left\{ (u, z, t, \delta) \to K^0 \left( \frac{\psi(\alpha, u) - \psi(\alpha, x)}{b_n} \right) \zeta_\alpha(x, u, z, t, \delta) : \alpha \in \mathcal{A}, x \in \mathcal{X} \right\}
\]
(A.7)
is a VC-class of functions for a constant envelope, assume that \( E[|\xi(T)|^3] < \infty \), and that \( nb_n^3/(\log n) \to \infty \). Then,
\[
n^{-1/2}b_n^{-1/2}[\log(1/b_n)]^{-1} \|\nu_n\|_G = O_P(1),
\]
where \( \| \cdot \|_G \) denotes the uniform norm over all maps in \( G \).

Remark. Note that if \( K^0 \) is of bounded variation with compact support, and if \( \psi(\alpha, x) = \alpha'x \), then (A.7) holds, see Nolan and Pollard (1987).

Proof of Lemma A.1. As the class \( G \) is not necessarily uniformly bounded, introduce a truncation bound \( M_n \), and consider the class \( \mathcal{G}_n \) of functions \( g_{\alpha, x, v}(x, z, t, \delta) = g_{\alpha, x, v}(x, z, t, \delta) 1_{|\xi(t)| \leq M_n} \). We set \( M_n = (nb_n)^{1/2} \). Apply Proposition 1 in Einmahl and Mason (2005) to the class of functions \( \mathcal{G}_n \). Their condition 1 holds, taking the envelope \( G(u, z, t, \delta) = M_n\|K^0\|_{\infty} \), and \( \beta = c_1 b_n^{1/2} \), for some \( c_1 > 0 \). Condition 2 holds as the class \( \mathcal{G}_n \) is VC. Indeed, the class \( t \to 1_{t \leq v} \) indexed by \( v \in \mathbb{R} \) is VC (see Example 19.6 in Van der Vaart, 1998), and hence (A.7) and Lemma 2.14 (ii) in Pakes and Pollard (1989) yield that \( \mathcal{G}_n \) satisfies their condition 2, whereas condition 3 holds for \( \sigma_0 = \sigma = c_2 b_n \), for some \( c_2 > 0 \). For condition 4, we have
\[
\sup_{g \in \mathcal{G}_n} \|g\|_{\infty} \leq M_n\|K^0\|_{\infty} \leq c_3 \sqrt{n \sigma^2},
\]
for some constant \( c_3 > 0 \).

Applying Proposition 1 in Einmahl and Mason (2005), we can deduce that, for any \( M < \infty \) sufficiently large, for all \( u' > 0 \) and for some \( A_1 > 0 \),
\[
\mathbb{P} \left( \|\nu_n\|_{\mathcal{G}_n} \geq M(nb_n)^{1/2}(\log b_n^{-1})^{1/2} \right) \\
\leq \mathbb{P} \left( \|\nu_n\|_{\mathcal{G}_n} \geq A_1 \left( E \left[ \sup_{g \in \mathcal{G}_n} \left| \sum_{i=1}^{n} \varepsilon_i g(W_i) \right| \right] + u' \right) \right),
\]
where \( W_i = (X_i', Z_i, T_i, \delta_i)' \) and \( \varepsilon_1, \ldots, \varepsilon_n \) is a sequence of independent Rademacher random variables, independent of \( W_1, \ldots, W_n \). Now we can apply Talagrand’s inequality (1994), see also Einmahl and Mason (2005). Taking \( u' = \sqrt{nb_n \log b_n^{-1}} \), deduce that
\[
\|\nu_n\|_{\mathcal{G}_n} = O_P \left( (nb_n)^{1/2}(\log b_n^{-1})^{1/2} \right).
\]
Now, for some \( c_4 > 0 \),
\[
\|\nu_n\|_G \leq \|\nu_n\|_{G_n} + c_4 \sum_{i=1}^{n} |\xi(T_i)| 1_{|\xi(T_i)| \geq M_n}.
\]

The second term on the right hand side is of the order \( O_P(b_n^{-1}) = o_P((\log n)^{1/2} n^{1/2} b_n^{1/2}) \).
Indeed, its expectation can be bounded, using Hölder’s inequality, by \( nE[|\xi(T)|^{3}]^{1/3} \mathbb{P}(|\xi(T)| \geq M_n)^{2/3} \). Using Chebyshev’s inequality,
\[
\mathbb{P}(|\xi(T)| \geq M_n) \leq E \left[ \frac{|\xi(T)|^{3}}{M_n^{3}} \right] = O(n^{-3/2} b_n^{-3/2}).
\]

The second technical lemma shows the consistency of the estimator \( \hat{\theta}_n(t|\lambda(\theta, x)) \) and its vector of partial derivatives, uniformly in \( t, \theta \) and \( x \), and it also establishes the rate of convergence of the estimator \( \hat{\theta}_n(t|\hat{g}(x)) \), uniformly in \( t \) and \( x \).

**Lemma A.2** Under the assumptions of Theorem [12] we have
\[
\sup_{t \leq \tau, \theta \in \Theta, x \in \mathcal{X}} |\hat{G}_\theta(t|\lambda(\theta, x)) - G_\theta(t|\lambda(\theta, x))| = o_P(1),
\]
(A.8)
\[
\sup_{t \leq \tau, \theta \in \Theta, x \in \mathcal{X}} |\nabla \theta \hat{G}_\theta(t|\lambda(\theta, x)) - \nabla \theta G_\theta(t|\lambda(\theta, x))| = o_P(1),
\]
(A.9)
\[
\sup_{t \leq \tau} \sup_{x: \hat{g}(x) \in \mathcal{Z}_{\hat{\theta}_n}} |\hat{G}_\theta(t|\hat{g}(x)) - G_{\hat{\theta}_n}(t|\hat{g}(x))| = O_P(n^{-1/2} a_n^{-1/2} (\log n)^{1/2}).
\]
(A.10)

**Proof.** For the first part, with probability tending to 1, \( t \leq \tau, 1 - \hat{G}(t|\lambda(\theta, x)) > 0 \).
Taking the logarithm, one obtains
\[
\log(1 - \hat{G}(t|\lambda(\theta, x))) = \sum_{i=1}^{n} (1 - \delta_i) 1_{T_i \leq t} \log (1 - W_{n,i}(x, \theta)),
\]
where
\[
W_{n,i}(x, \theta) = W_n(X_i, T_i; x, \theta) = \frac{K \left( \frac{\lambda(\theta, X_i) - \lambda(\theta, x)}{\alpha_n} \right)}{\sum_{j=1}^{n} 1_{T_j \geq T_i} K \left( \frac{\lambda(\theta, X_j) - \lambda(\theta, x)}{\alpha_n} \right)}.
\]
A Taylor expansion leads to
\[
\log(1 - \hat{G}(t|\lambda(\theta, x))) = - \sum_{i=1}^{n} (1 - \delta_i) W_{n,i}(x, \theta) 1_{T_i \leq t} + O_P(n^{-1} a_n^{-2}),
\]
where the order of the remainder term is uniform in \( t, \theta, x \), as
\[
\sup_{i: T_i \leq \tau} \sup_{x, \theta} |W_{n,i}(x, \theta)| = O_P(n^{-1} a_n^{-1}).
\]

20
The remainder term is $o_P(1)$ if $na_n^2 \to \infty$. Rewrite

$$
\sum_{i=1}^{n}(1 - \delta_i)1_{T_i \leq t}W_{n,i}(x, \theta) = \frac{1}{na_n} \sum_{i=1}^{n}(1 - \delta_i)1_{T_i \leq t}K\left(\frac{\lambda(\theta, X_i) - \lambda(\theta, x)}{a_n}\right)S_\theta(\lambda(\theta, x), T_i)^{-1} + \frac{1}{na_n} \sum_{i=1}^{n}(1 - \delta_i)1_{T_i \leq t}K\left(\frac{\lambda(\theta, X_i) - \lambda(\theta, x)}{a_n}\right)$$

$$\times \frac{\hat{S}_\theta(\lambda(\theta, x), T_i) - S_\theta(\lambda(\theta, x), T_i)}{S_\theta(\lambda(\theta, x), T_i)\hat{S}_\theta(\lambda(\theta, x), T_i)}$$

where

$$S_\theta(\lambda(\theta, x), y) = [1 - H_\theta(y|\lambda(\theta, x))]f_Z_\theta(\lambda(\theta, x)),$$

$$\hat{S}_\theta(\lambda(\theta, x), y) = \frac{1}{na_n} \sum_{j=1}^{n}1_{T_j \geq y}K\left(\frac{\lambda(\theta, X_j) - \lambda(\theta, x)}{a_n}\right).$$

Apply Lemma A.1 to obtain the uniform convergence of $\hat{S}_\theta$ towards $S_\theta$, and to show that

$$\sup_{x, \delta \in \Theta, t \leq \tau} \left| \frac{1}{na_n} \sum_{i=1}^{n}(1 - \delta_i)1_{T_i \leq t}K\left(\frac{\lambda(\theta, X_i) - \lambda(\theta, x)}{a_n}\right)S_\theta(\lambda(\theta, x), T_i)^{-1} - \int_{-\infty}^{t} \frac{dH_{\theta, \theta}(s|\lambda(\theta, x))}{1 - H_\theta(s - |\lambda(\theta, x)|)} \right| = o_P(1).$$

Since $S_\theta$ is uniformly bounded away from zero for $y \leq \tau$, see Assumption [\textbf{A1}] the result follows from

$$\exp\left[ - \int_{-\infty}^{t} \frac{dH_{\theta, \theta}(s|\lambda(\theta, x))}{1 - H_\theta(s - |\lambda(\theta, x)|)} \right] = 1 - G_\theta(t|\lambda(\theta, x)).$$

For the gradient, we have

$$\nabla_\theta \hat{G}_\theta(t|\lambda(\theta, x)) = (1 - \hat{G}_\theta(t|\lambda(\theta, x))) \sum_{i=1}^{n}(1 - \delta_i)1_{T_i \leq t} \frac{\nabla_\theta W_{n,i}(x, \theta)}{1 - W_{n,i}(x, \theta)}.$$ 

From this, we deduce that the convergence of $\nabla_\theta \hat{G}_\theta$ follows from the convergence of $\hat{G}_\theta$, of $\hat{S}_\theta$ and of

$$\frac{1}{na_n^2} \sum_{i=1}^{n}(1 - \delta_i)1_{T_i \leq t} \frac{\nabla_\theta \lambda(\theta, x)K'}{a_n}\left(\frac{\lambda(\theta, X_i) - \lambda(\theta, x)}{a_n}\right),$$

and

$$\frac{1}{na_n^2} \sum_{i=1}^{n}1_{T_i \leq t} \frac{\nabla_\theta \lambda(\theta, x)K'}{a_n}\left(\frac{\lambda(\theta, X_i) - \lambda(\theta, x)}{a_n}\right).$$

21
These two quantities can be studied using Lemma A.1, which shows that their centered versions converge uniformly with rate $(n_0^n)^{-1/2} \log n$, while the bias term is of order $a^2$.

The third result can be deduced from a Taylor expansion, Assumption 5 and Proposition 4.3 in Van Keilegom and Akritas (1999). Indeed, we can deduce that

$$
\sup_{t \leq \tau} \sup_{x, \mu(x) \in \mathcal{Z}_{0, \eta}} |\hat{G}_{\hat{\theta}}(t|\hat{\mu}(x)) - G_{\theta_0}(t|\mu(x))| \\
\leq \sup_{t \leq \tau} \sup_{x, \mu(x) \in \mathcal{Z}_{0, \eta}} |\hat{G}_{\theta_0}(t|\mu(x)) - G_{\theta_0}(t|\mu(x))| + O_P(\|\hat{\theta} - \theta_0\|).
$$

\[\square\]

We are now ready to give the proofs of the main results.

**Proof of Theorem 3.2** Part i) of the Theorem can be easily derived by replacing the differentiability condition in Assumption 5 by a uniform continuity condition on $G_{\theta}$ with respect to $\theta$, and equation (A.8) in Lemma A.2.

For part ii), a Taylor expansion with respect to $\theta$ leads to

$$
\int \phi(x, y) d[\hat{F}_\theta - \hat{F}_{\theta_0}](x, y) = -\frac{1}{n} \sum_{i=1}^{n} \frac{\delta_i \phi(X_i, T_i) \nabla_\theta \hat{G}_{\theta_0}(T_i - |\lambda(\theta_0, X_i)))(\hat{\theta} - \theta_0)}{[1 - \hat{G}_{\theta_0}(T_i - |\lambda(\theta_0, X_i))]^2},
$$

for some $\theta_n$ between $\hat{\theta}$ and $\theta_0$. From the convergence of $\hat{\theta}$ towards $\theta_0$, it follows that $\theta_n$ tends to $\theta_0$. Moreover, applying equation (A.8) and (A.9) in Lemma A.2 we obtain that

$$
\int \phi(x, y) d[\hat{F}_\theta - \hat{F}_{\theta_0}](x, y) = -\frac{1}{n} \sum_{i=1}^{n} \frac{\delta_i \phi(X_i, T_i) \nabla_\theta G_{\theta_0}(T_i - |\lambda(\theta_0, X_i)))(\hat{\theta} - \theta_0)}{[1 - G_{\theta_0}(T_i - |g(X_i))]^2} + R_n(\phi),
$$

$$
= U_n(\phi) + R_n(\phi),
$$

with $\sup_\phi |R_n(\phi)| \leq |R_n(\Phi)| = o_P(n^{-1/2})$, and

$$
U_n(\phi) = \left\{-\frac{1}{n} \sum_{i=1}^{n} \frac{\delta_i \phi(X_i, T_i) \nabla_\theta G_{\theta_0}(T_i - |\lambda(\theta_0, X_i))}{[1 - G_{\theta_0}(T_i - |g(X_i))]^2}\right\} \left\{\frac{1}{n} \sum_{j=1}^{n} \mu(T_j, \delta_j, X_j)\right\} + R'_n(\phi),
$$

with $\sup_\phi |R'_n(\phi)| \leq |R'_n(\Phi)| = o_P(n^{-1/2})$. Centering the first sum in $U_n(\phi)$ and applying a uniform Central Limit Theorem (see e.g. Van der Vaart and Wellner, 1996), we obtain the stated representation. \[\square\]
Proof of Theorem 3.3. Consider the difference
\[ |M_n(\beta, \hat{f}, \hat{J}) - M_n(\beta, f, \hat{J})| \]
\[ \leq 2 \int |y|1_{y \leq \tau} d\hat{F}_y(x, y) \sup_{x: \hat{J}(x) = 1, \beta \in B} |\hat{f}(\beta' x; \beta) - f(\beta' x; \beta)| \]
\[ + \int 1_{y \leq \tau} |\hat{f}(\beta' x; \beta) + f(\beta' x; \beta)| d\hat{F}_y(x, y) \sup_{x: \hat{J}(x) = 1, \beta \in B} |\hat{f}(\beta' x; \beta) - f(\beta' x; \beta)|. \]
The first term on the right hand side converges uniformly to zero by Assumption 9 and the law of large numbers for \( \hat{F}_y \) (see Theorem 3.1 and Theorem 3.2). The integral in the second term can be bounded by
\[ (1 + o_P(1)) \times \int 2\Psi(x) d\hat{F}_y(x, y), \]
where \( o_P(1) \) is uniform in \( \beta \), by Assumption 7 and [A.1]. Now we have to show that \( M_n(\beta, f, J^*) \) converges to \( M(\beta, f, J^*) \) uniformly in \( \beta \). For this, apply Theorem 3.1 and Theorem 3.2 using Assumption 7 By usual arguments for proving consistency (see e.g. Van der Vaart, 1998, Theorem 5.7), the consistency of \( \beta_n \) follows. \( \square \)

Proof of Lemma 3.4. The proof is somewhat similar to the proof of Lemma 5A in Dominitz and Sherman (2005). First observe that
\[ f(\beta' X; \beta) = E[Y \mid \beta' X, Y \leq \tau] = E[f(\beta'_0 X; \beta_0) \mid \beta' X, Y \leq \tau] = \frac{E[f(\beta'_0 X; \beta_0)1_{Y \leq \tau} \mid \beta' X]}{P(Y \leq \tau \mid \beta' X)}. \]
Let \( \alpha(X, \beta) = \beta'_0 X - \beta' X \). Define
\[ \Gamma_X(\beta_1, \beta_2) = E[f(\alpha(X, \beta_1) + \beta'_2 X; \beta_0)1_{Y \leq \tau} \mid \beta'_2 X], \]
and note that \( f(\beta' X; \beta) = \Gamma_X(\beta, \beta)/P(Y \leq \tau \mid \beta' X) \). Then,
\[ \nabla_{\beta_1} \Gamma_X(\beta_0, \beta_0) = -f'(\beta'_0 X; \beta_0)E[XP(Y \leq \tau \mid X) \mid \beta'_0 X], \]
\[ \nabla_{\beta_2} \Gamma_X(\beta_0, \beta_0) = f'(\beta'_0 X; \beta_0)XP(Y \leq \tau \mid \beta'_0 X) + f(\beta'_0 X; \beta_0)\nabla_{\beta_0} h(X, \beta_0), \]
where \( h(x, \beta) = P(Y \leq \tau \mid \beta' X = \beta' x) \). It follows that
\[ \nabla_{\beta} f(\beta'_0 x; \beta_0) = f'(\beta'_0 x; \beta_0) \{ xP(Y \leq \tau \mid \beta'_0 X = \beta'_0 x) - E[XP(Y \leq \tau \mid X) \mid \beta'_0 X = \beta'_0 x]\} \]
\[ \frac{P(Y \leq \tau \mid \beta'_0 X = \beta'_0 x)}{P(Y \leq \tau \mid \beta'_0 X = \beta'_0 x)} \]
\[ + \frac{\nabla_{\beta} h(x, \beta_0)f(\beta'_0 x; \beta_0)}{P(Y \leq \tau \mid \beta'_0 X = \beta'_0 x)} \frac{\nabla_{\beta} h(x, \beta_0)f(\beta'_0 x; \beta_0)E[1_{Y \leq \tau} \mid \beta'_0 X = \beta'_0 x]}{P(Y \leq \tau \mid \beta'_0 X = \beta'_0 x)^2} \]
\[ := x m_1(\beta'_0 x) + m_2(\beta'_0 x). \quad (A.11) \]
Therefore,
\[
E \left[ \nabla_{\beta} f(\beta'_0 X; \beta_0) 1_{Y \leq \tau} | \beta'_0 X \right] \\
= E \left[ f'(\beta'_0 X; \beta_0) \{ X \mathbb{P}(Y \leq \tau | \beta'_0 X) - E [X \mathbb{P}(Y \leq \tau | X) | \beta'_0 X] \} 1_{Y \leq \tau} | \beta'_0 X \right] \\
= 0.
\]

\[\square\]

**Proof of Theorem 3.5.** The proof consists of three steps:

**Step 0:** Replace \( J \) by \( J_0 \). For any \( \mathcal{B}_n \) a sequence of shrinking neighborhoods of \( \beta_0 \),
\[
\sup_{\beta \in \mathcal{B}_n} \left| M_n(\beta, \hat{f}, J) - M_n(\beta, \hat{f}, J_0) \right| \leq o_P(M_n(\beta, \hat{f}, J_0 + n^{-1}).
\]
See Delecroix, Hristache and Patilea (2006), page 738. Similar arguments apply also when the trimming \( J \) is defined with \( \hat{f}_{\beta_n}(\beta_n x) \) justifying the practical implementation of the trimming function.

**Step 1:** Bring the problem back to the parametric case.

For notational simplicity, we work with \( \nabla_{\beta} f \) instead of \( \nabla_{\beta} f \). Note that \( \nabla_{\beta} f = (0, \nabla'_{\beta} f)' \). We will show that, on \( \mathcal{B}_n \),
\[
M_n(\beta, \hat{f}, J_0) = M_n(\beta, f, J_0) + o_P\left( \frac{\|\beta - \beta_0\|}{\sqrt{n}} \right) + o_P\left( \|\beta - \beta_0\|^2 \right) + C'_n,
\]
where \( C'_n \) does not depend on \( \beta \). Decompose
\[
M_n \left( \beta, \hat{f}, J_0 \right) = M_n \left( \beta, f, J_0 \right) \\
- \frac{2}{n} \sum_{i=1}^{n} \frac{\delta_i J_0(X_i) \delta_i J_0(X_i) \delta_i J_0(X_i) \delta_i J_0(X_i) \delta_i J_0(X_i) \delta_i J_0(X_i) \delta_i J_0(X_i) \delta_i J_0(X_i) \delta_i J_0(X_i)}{1 - G_0(T_i - |\hat{g}(X_i)|)} \left[ \hat{f} (\beta' X_i; \beta) - f (\beta' X_i; \beta) \right]^2 \\
+ \frac{1}{n} \sum_{i=1}^{n} \frac{\delta_i J_0(X_i) \delta_i J_0(X_i) \delta_i J_0(X_i) \delta_i J_0(X_i) \delta_i J_0(X_i) \delta_i J_0(X_i) \delta_i J_0(X_i) \delta_i J_0(X_i) \delta_i J_0(X_i)}{1 - G_0(T_i - |\hat{g}(X_i)|)} \left[ \hat{f} (\beta' X_i; \beta) - f (\beta' X_i; \beta) \right]^2 \\
= M_n \left( \beta, f, J_0 \right) - 2A_{1n} + B_{1n}.
\]

**Step 1.1:** Study of \( A_{1n} \).
Taylor expansion applied twice (for $f$ that

Next, a second order Taylor development shows that the first term above can be rewritten using part 2 of Assumption 11, and Lemma A.2. A first order Taylor expansion for $J$ away from zero with probability tending to 1 for $A_{1n} = \frac{1}{n} \sum_{i=1}^{n} \delta_{i} J_{0}(X_{i}) \left( T_{i} - f(\beta_{0}X_{i}; \beta_{0}) \right) 1_{T_{i} \leq \tau} \left[ \hat{f}(\beta_{0}X_{i}; \beta_{0}) - f(\beta_{0}X_{i}; \beta_{0}) \right]

+ \frac{1}{n} \sum_{i=1}^{n} \delta_{i} J_{0}(X_{i}) 1_{T_{i} \leq \tau} \left( f(\beta_{0}X_{i}; \beta_{0}) - f(\beta'X_{i}; \beta) \right)

\times \left[ \hat{f}(\beta'X_{i}; \beta) - f(\beta'X_{i}; \beta) - \hat{f}(\beta_{0}X_{i}; \beta) + f(\beta'X_{i}; \beta) \right]

+ \frac{1}{n} \sum_{i=1}^{n} \delta_{i} J_{0}(X_{i}) \left( T_{i} - f(\beta'X_{i}; \beta) \right) 1_{T_{i} \leq \tau} \left[ \hat{f}(\beta_{0}X_{i}; \beta_{0}) - f(\beta_{0}X_{i}; \beta_{0}) \right]

+ \frac{1}{n} \sum_{i=1}^{n} \delta_{i} J_{0}(X_{i}) \left( T_{i} - f(\beta'X_{i}; \beta) \right) 1_{T_{i} \leq \tau} \left[ \hat{f}(\beta_{0}X_{i}; \beta_{0}) - f(\beta'X_{i}; \beta) \right]

\times \left[ \hat{f}(\beta'X_{i}; \beta) - f(\beta'X_{i}; \beta) - \hat{f}(\beta_{0}X_{i}; \beta) + f(\beta_{0}X_{i}; \beta) \right]

= A_{2n} + A_{3n} + A_{4n} + A_{5n}.

A_{2n} does not depend on $\beta$. For $A_{3n}$, observe that, for any $\beta \in \mathcal{B}_{n}$, we can replace $J_{0}(X_{i})$ by $1_{f_{\beta}(\beta'X_{i}); \beta' > c/2}$ using Assumption 4. As $\nabla_{\beta}f(\beta'x; \beta)$ is a bounded function of $x$ and $\beta$ (Assumption 3 since the class of functions has a bounded envelope), and using the uniform convergence of $\nabla_{\beta}\hat{f}(\beta'x; \beta)$ (Assumption 5), we can obtain from a first order Taylor expansion applied twice (for $f(\beta'x; \beta)$ and for $\hat{f}(\beta'x; \beta) - f(\beta'x; \beta)$ around $\beta_{0}$), that $A_{3n} = o_{p}(\|\beta - \beta_{0}\|^{2})$.

For $A_{4n}$, first replace $\hat{G}_{\theta}$ with $G_{\theta_{0}}$. For this, note that $[1 - G_{\theta_{0}}(T_{i} - |g(X_{i})|)]$ is bounded away from zero with probability tending to 1 for $T_{i} \leq \tau$, and that

$$\sup_{t \leq \tau, x, J_{0}(x) = 1} \left| \hat{G}_{\theta}(t|\hat{g}(x)) - G_{\theta_{0}}(t|g(x)) \right| = o_{p}(n^{-1/2}) \quad (A.12)$$

using part 2 of Assumption 11 and Lemma A.2. A first order Taylor expansion for $f(\beta'x; \beta) - f(\beta'x; \beta_{0})$ and property (A.12) lead to

$$A_{4n} = \frac{1}{n} \sum_{i=1}^{n} \delta_{i} J_{0}(X_{i}) 1_{T_{i} \leq \tau} \left( f(\beta'X_{i}; \beta_{0}) - f(\beta'X_{i}; \beta) \right) \left[ \hat{f}(\beta_{0}X_{i}; \beta_{0}) - f(\beta_{0}X_{i}; \beta_{0}) \right]

+ o_{p} \left( \frac{\|\beta - \beta_{0}\|}{\sqrt{n}} \right).$$

Next, a second order Taylor development shows that the first term above can be rewritten
as

$$
\frac{(\beta - \beta_0)^r}{n} \sum_{i=1}^{n} \frac{\delta_i J_0(X_i) 1_{T_i \leq \tau} \nabla f(\beta_0' X_i; \beta_0)}{1 - G_{\theta_0}(T_i - |g(X_i)|)} \left[ f(\beta_0' X_i; \beta_0) - \hat{f}(\beta_0' X_i; \beta_0) \right]
+ o_P(\|\beta - \beta_0\|^2).
$$

(A.13)

To show that this term is negligible, we will use empirical process theory. We have that $f \in \mathcal{H}_1$, where $\mathcal{H}_1$ is the Donsker class defined in Assumption 10 and $\hat{f} \in \mathcal{H}_1$ with probability tending to 1. Consequently, the class of functions

$$
\mathcal{H}_1' = \left\{ (y, c, x, t) \rightarrow \frac{1_{y \leq \tau} \nabla f(\beta_0' X; \beta_0) \phi(\beta_0' X) 1_{T \leq \tau}}{1 - G_{\theta_0}(y \wedge c - |g(x)|)} : \phi \in \mathcal{H}_1 \right\}
$$

is a Donsker class, see Example 2.10.8 in Van der Vaart and Wellner (1996). Furthermore, for all $\phi \in \mathcal{H}_1$,

$$
E \left[ \frac{\delta J_0(X) \nabla f(\beta_0' X; \beta_0) \phi(\beta_0' X) 1_{T \leq \tau}}{1 - G_{\theta_0}(T - |g(X)|)} \right] = E \left[ \nabla f(\beta_0' X; \beta_0) \phi(\beta_0' X) J_0(X) 1_{Y \leq \tau} \right] = 0,
$$

(A.14)

since $E[\nabla f(\beta_0' X; \beta_0) 1_{Y \leq \tau}] = 0$ (see Lemma 3.4), and since $J_0(X)$ is a function of $\beta_0' X$ alone. Deduce that, since $\mathcal{H}_1'$ is a Donsker class, and since $\hat{f}$ tends uniformly to $f$, that the first term in (A.13) is of order $o_P(\|\beta - \beta_0\|n^{-1/2})$. See the asymptotic equicontinuity of Donsker classes, cf. Van der Vaart and Wellner (1996), Section 2.1.2.

For $A_{5n}$, apply a second order Taylor expansion. Using that $\nabla^2 f$ is bounded, and that $\nabla^2 \hat{f}$ converges uniformly to $\nabla^2 f$, we obtain

$$
A_{5n} = \frac{(\beta - \beta_0)^r}{n} \sum_{i=1}^{n} \frac{\delta_i J_0(X_i) 1_{T_i \leq \tau} (T_i - f(\beta_0' X_i; \beta_0)) [\nabla f(\beta_0' X_i; \beta_0) - \nabla \hat{f}(\beta_0' X_i; \beta_0)]}{1 - G_{\theta_0}(T_i - |g(X_i)|)}
+ o_P(\|\beta - \beta_0\|^2).
$$

Proceed as for $A_{4n}$ to replace $\hat{G}$ and $\hat{g}$ by $G$ and $g$, using part 3 of Assumption 11. The same arguments as for $A_{4n}$ can then be used, but considering instead the Donsker class

$$
\mathcal{H}_2' = \left\{ (y, c, x) \rightarrow \frac{1_{y \leq \tau} J_0(x) 1_{y \leq \tau} (y - f(\beta_0' X; \beta_0)) \phi(x)}{1 - G_{\theta_0}(y - |g(x)|)} : \phi \in \mathcal{H}_2 \right\},
$$

where $\mathcal{H}_2$ is defined in Assumption 10 and observing that, for any function $\phi$,

$$
E \left[ \frac{\delta J_0(X) \phi(X) (Y - f(\beta_0' X; \beta_0)) 1_{T \leq \tau}}{1 - G_{\theta_0}(T - |g(X)|)} \right]
= E \left[ E \left[ (Y - f(\beta_0' X; \beta_0) 1_{Y \leq \tau} | X] J_0(X) \phi(X) \right] \right] = 0,
$$

26
by the definition of our regression model. Deduce that \( A_{5n} = o_P(\|\beta - \beta_0\| n^{-1/2} + \|\beta - \beta_0\|^2) \).

**Step 1.2 : Study of \( B_{1n} \)**

Rewrite \( B_{1n} \) as

\[
B_{1n} = \frac{1}{n} \sum_{i=1}^{n} \frac{\delta_i J_0(X_i) 1_{T_i \leq \tau}}{1 - G_\theta(T_i - |\hat{g}(X_i)|)}
\times \left[ \hat{f}(\beta'X_i; \beta) - f(\beta'X_i; \beta) - \hat{f}(\beta_0'X_i; \beta_0) + f(\beta_0'X_i; \beta_0) \right]^2
\]

\[
+ \frac{1}{n} \sum_{i=1}^{n} \frac{\delta_i J_0(X_i) 1_{T_i \leq \tau}}{1 - G_\theta(T_i - |\hat{g}(X_i)|)} \left[ \hat{f}(\beta_0'X_i; \beta_0) - f(\beta_0'X_i; \beta_0) \right]^2
\]

\[
+ \frac{2}{n} \sum_{i=1}^{n} \delta_i J_0(X_i) 1_{T_i \leq \tau} \left[ \hat{f}(\beta_0'X_i; \beta_0) - f(\beta_0'X_i; \beta_0) \right]
\times \left[ \hat{f}(\beta'X_i; \beta) - f(\beta'X_i; \beta) - \hat{f}(\beta_0'X_i; \beta_0) + f(\beta_0'X_i; \beta_0) \right]
\]

\[
= B_{2n} + B_{3n} + 2B_{4n}.
\]

Observe that, for any \( \beta \in \mathcal{B}_n \), we can replace \( J_0(X_i) \) by \( 1_{f_\beta'(\beta'X_i) > c/2} \) using Assumption \( \mathfrak{8} \). Next, by a Taylor expansion and the uniform convergence of \( \nabla_\beta \hat{f} \), we have that \( B_{2n} = o_P(\|\beta - \beta_0\|^2) \). The term \( B_{3n} \) does not depend on \( \beta \). For \( B_{4n} \), a second order Taylor expansion leads to

\[
B_{4n} = \frac{(\beta - \beta_0)'}{n} \sum_{i=1}^{n} \frac{\delta_i J_0(X_i)}{1 - G_\theta(T_i - |\hat{g}(X_i)|)} \left[ \hat{f}(\beta_0'X_i; \beta_0) - f(\beta_0'X_i; \beta_0) \right]
\times [\nabla_\beta \hat{f}(\beta_0'X_i; \beta_0) - \nabla_\beta f(\beta_0'X_i; \beta_0)] + o_P(\|\beta - \beta_0\|^2).
\]

Replace \( \hat{G} \) by \( G \) and use Assumption \( \mathfrak{11} \) part 1, to conclude.

**Step 2 : Study of \( M_n(\beta, f, J_0) \).**

Observe that, on \( o_P(1) \)–neighborhoods of \( \beta_0 \), from a Taylor expansion,

\[
M_n(\tilde{\beta}, f, J_0) - M_n(\tilde{\beta}_0, f, J_0)
= (\tilde{\beta} - \tilde{\beta}_0)' \nabla_\beta M_n(\tilde{\beta}_0, f, J_0) + (\tilde{\beta} - \tilde{\beta}_0)'^2 \nabla^2_\beta \beta M_n(\tilde{\beta}_0, f, J_0)(\tilde{\beta} - \tilde{\beta}_0) + o_P(\|\tilde{\beta} - \tilde{\beta}_0\|^2),
\]

and apply Theorem 1 and 2 of Sherman (1994) to conclude. \( \square \)

**Proof of Proposition 3.6.** The uniform convergence results in Assumptions \( \mathfrak{9} \) and \( \mathfrak{11} \) can be deduced from studying the uniform convergence rate of the numerator and the denominator in \( 3.4 \) (and their derivatives) separately. This is a consequence of Lemma
A.1. Since the other terms can be studied in a similar way, we only consider the case of the denominator and its derivatives in (A.4). In each case, the bias part can be dealt with uniformly with classical kernel arguments, and is of order $h^2$. For the centered version of $f^*$, the result can be deduced from the study of the uniform convergence rate of empirical processes indexed by some class of functions as the one defined in (A.6), with

$$
\zeta_\beta(x, X, Z, T, \delta) = \frac{\delta(x - X)^j}{1 - G_{\theta_0}(T - \|Z\|)},
$$

where $j = 0$ (resp. 1, 2) for $f^*$ (resp. $\nabla_\beta f^*$, $\nabla^2_{\beta, \beta} f^*$), and $\xi(T) = T$. The kernel $K^0$ in (A.6) is either $\tilde{K}$ or $\tilde{K}'$ or $\tilde{K}''$, and $\psi(\beta, x) = \beta' x$. It follows from the conditions on $\tilde{K}$ and from Nolan and Pollard (1987) that the class of functions

$$\{x \to K^0 \left( \frac{\beta' x - \beta' u}{h} \right) : u \in \mathcal{X}, h > 0, \beta \in \mathcal{B} \}$$

is a VC-class of functions. Moreover $u \to (x - u)^j$ ($j = 0, 1, 2$) is also a VC-class of bounded functions using permanence properties of VC-classes, see Lemma 2.6.18 in Van der Vaart and Wellner (1996). Finally, since $1 - G_{\theta_0}(T - \|Z\|)$ is bounded away from zero, (A.7) holds. Now applying Lemma A.1, we get

$$
\sup_{\beta, x} |f^*(\beta' x; \beta) - f(\beta' x; \beta)| = O_P((\log n)^{1/2} n^{-1/2} h^{-1/2} + h^2),
$$

$$
\sup_{\beta, x} |\nabla_\beta f^*(\beta' x; \beta) - \nabla_\beta f(\beta' x; \beta)| = O_P((\log n)^{1/2} n^{-1/2} h^{-3/2} + h^2),
$$

$$
\sup_{\beta, x} |\nabla^2_{\beta, \beta} f^*(\beta' x; \beta) - \nabla^2_{\beta, \beta} f(\beta' x; \beta)| = O_P((\log n)^{1/2} n^{-1/2} h^{-5/2} + h^2),
$$

where $h^2$ comes from the bias term. Hence, Assumption (9) holds if $h \to 0$ and $nh^5 (\log n)^{-1/2} \to \infty$. Assumption (11) holds if $(\log n)^{-1} n^{1/2} a_n^{1/2} h \to \infty$, and $nh^8 \to 0$.

The first part of Assumption (10) follows directly from the uniform convergence of $f^*$. Elementary algebra shows that the gradient of $f^*$ can be written as

$$
\nabla_\beta f^*(\beta'_0 x; \beta_0) = x m_1^*(\beta'_0 x) + m_2^*(\beta'_0 x).
$$

(A.15)

Using the same arguments as above, these two functions converge uniformly to $m_1(\beta'_0 x)$ and $m_2(\beta'_0 x)$ respectively, where $\nabla_\beta f(\beta'_0 x; \beta_0) = x m_1(\beta'_0 x) + m_2(\beta'_0 x)$, see equation (A.11), and Assumption (10) follows.

Proof of Proposition 3.7. The result can be deduced from studying the following type
of quantities:

\[
(nh)^{-1} \sum_{i=1}^{n} \tilde{K}^{(j)} \left( \frac{\beta' x - \beta' X_i}{h} \right) (X_i - x)^j \delta_i T_i^{k} 1_{T_i \leq \tau} \left[ \frac{1}{1 - G_{\theta}(T_i - |\lambda(\theta, X_i)|)} \right]
\]

where \( j = 0, 1, 2 \) and \( k = 0, 1 \). Using Lemma A.2, equation (A.10), and the fact that

\[
\sup_{\beta} \left[ (nh)^{-1} \sum_{i=1}^{n} |\tilde{K}^{(j)}| \left( \frac{\beta' x - \beta' X_i}{h} \right) |T_i|^k \right] = O_P(1),
\]

we can deduce that this type of quantities is of the order \( O_P((\log n)^{1/2} h^{-j} n^{-1/2} a_n^{-1/2} ) \) \((j = 0, 1, 2)\). Hence the convergence rates follow.

\[\square\]
