Flavor structure in D-brane models: Majorana neutrino masses

Yuta Hamada, Tatsuo Kobayashi, and Shohei Uemura

Department of Physics, Kyoto University, Kyoto 606-8502, Japan

Abstract

We study the flavor structure in intersecting D-brane models. We study anomalies of the discrete flavor symmetries. We analyze the Majorana neutrino masses, which can be generated by D-brane instanton effects. It is found that a certain pattern of mass matrix is obtained and the cyclic permutation symmetry remains unbroken. As a result, trimaximal mixing matrix can be realized if Dirac neutrino mass and charged lepton mass matrices are diagonal.
1 Introduction

The Standard Model has been confirmed by the discovery of the Higgs scalar and other precision measurements. However, it has various mysteries still. One of them is the mystery on the flavor structure. Why are there three generations? Why are quark and lepton masses hierarchical? Which mechanism determines their mixing angles? Indeed, the Yukawa sector has most of free parameters in the Standard model. Discrete flavor symmetries would be important to understand fermion masses and mixing angles \[1, 2, 3\]. For example, the mixing matrix in the lepton sector, the PMNS matrix, can be approximated by the tri-bimaximal mixing matrix in the limit \(\theta_{13} = 0\) \[4\]. In field-theoretical model building, one starts with a large flavor symmetry. Then, one assumes that the flavor symmetry breaks properly into \(Z_3\) and \(Z_2\) subsymmetries in the charged lepton or the neutrino masses, such that the tri-bimaximal mixing can be realized.

Superstring theory is a promising candidate for unified theory of all of the interactions including gravity and all of the matter fields and Higgs field(s) (see for a review \[5\]). It is found that superstring theory on six-dimensional compact space leads to interesting flavor structures. In particular, certain types of four-dimensional superstring models with rather simple six-dimensional compact spaces such as tori and orbifolds lead to definite discrete flavor symmetries. For example, intersecting D-brane models and magnetized D-brane models are among interesting model building in superstring theory \[6, 7, 8, 9, 10, 11\] (see for review \[12, 5\] and references therein). These intersecting/magnetized D-brane models can lead to discrete flavor symmetries such as \(D_4\), \(\Delta(27)\), \(\Delta(54)\) \[13, 14, 15\]. Similar discrete flavor symmetries can be derived in heterotic string theory on orbifolds \[10\]. In these models, we can calculate explicitly Yukawa couplings and higher order couplings \[18, 19, 20\].

However, such discrete flavor symmetries may be broken by non-perturbative effects. From such a viewpoint, anomalies of discrete symmetries \[29, 30, 27, 28, 25\] are important because anomalous symmetries may be broken by non-perturbative effects. Even anomaly-free U(1) gauge symmetries can be broken when axions couple with U(1) gauge bosons and they become massive. Furthermore, as concrete non-perturbative effects, D-brane instanton effects have been studied \[31\] (see also for a review \[32\] and references therein). From the viewpoint of flavor physics, one of important points is that D-brane instanton effects can generate right-handed Majorana neutrino masses \[33, 34, 35\]. Then, it is also important to investigate patterns of right-handed Majorana neutrino mass matrices derived by D-brane instanton effects and study whether such effects break some or all of discrete flavor symmetries and which symmetries remain unbroken.

In this paper, we study the flavor structure in intersecting D-brane models as well as magnetized D-brane models. We study anomalies of discrete flavor symmetries derived in intersecting D-brane models. We also study right-handed Majorana neutrino mass matrices, which can be generated by D-brane instanton effects. We show which types of Majorana mass matrices can be derived and which flavor symmetries remain unbroken.

even with right-handed Majorana neutrino mass matrices generated by D-brane instanton effects.

This paper is organized as follows. In section 2, we review briefly the discrete flavor symmetries derived from intersecting D-brane models as well as magnetized D-brane models. In section 3, we study anomalies of these discrete flavor symmetries. In section 4, we study right-handed Majorana masses generated by D-brane instanton effects. Section 5 is devoted to conclusion and discussion.

2 Discrete flavor symmetries

In this section, we review briefly discrete flavor symmetries appearing in intersecting D-brane models as well as magnetized D-brane models \[13, 15\]. For concreteness, we consider IIA D6-brane models on \( T^6 = T^2_1 \times T^2_2 \times T^3_3 \), where each D6-brane wraps one-cycle of each \( T^2 \) of \( T^6 = T^2_1 \times T^2_2 \times T^3_3 \). That is, our setup is as follows. We consider \( N_a \) stacks of D6-branes, which lead to \( U(N_a) \) gauge symmetry, and they have winding numbers \((n_a^i, m_a^i)\) along the \( x_i \) and \( y_i \) directions on \( T^2_i \), where we use orthogonal coordinates \((x_i, y_i)\) on \( T^2_i \). When we denote the basis of one-cycles on \( T^2_i \) by \([a_i]\) and \([b_i]\), which correspond to the \( x_i \) and \( y_i \) directions, the three-cycle, along which this set of D6-brane winds, is represented by

\[
[\Pi_a] = \prod_{i=1}^{3} (n_a^i [a_i] + m_a^i [b_i]).
\] (2.1)

Here, we consider two sets of D-branes, one set is \( N_a \) stacks of D6-branes and another is \( N_b \) stacks of D6-branes. These lead to \( U(N_a) \times U(N_b) \) gauge groups. Suppose that these two stacks of D6-branes intersect each other on \( T^2_i \). Their intersecting number on \( T^2_i \) is obtained by

\[
I_{ab}^{(i)} = (n_a^i m_b^i - m_a^i n_b^i),
\] (2.2)

and their total intersecting number on \( T^6 \) is obtained by

\[
[\Pi_a] \cdot [\Pi_b] = I_{ab} = \prod_{i=1}^{3} I_{ab}^{(i)}.
\] (2.3)

Then, chiral matter fields with bi-fundamental representations \((N_a, \bar{N}_b)_{(1,-1)}\) under \( U(N_a) \times U(N_b) \) appear at intersecting points on \( T^2_i \); where the index \((1,-1)\) denotes \( U(1)^2 \) charges inside \( U(N_a) \) and \( U(N_b) \). There appear \( I_{ab} \) families of bi-fundamental matter fields. When \( I_{ab} \) is negative, there appear \(|I_{ab}|\) families of matter fields with the conjugate representation \((\bar{N}_a, N_b)_{(-1,1)}\).

The total flavor symmetry is a direct product of flavor symmetries appearing on one of \( T^2_i \). Thus, we concentrate on the flavor symmetry realized on one of \( T^2_i \). Then, we
denote $I_{ab}^{(i)} = g$. These modes on $T_i^2$ have definite $Z_g$ charges and $Z_g$ transformation is represented by

$$Z = \begin{pmatrix} 1 & & & & \\ \rho & 1 & & & \\ & \rho^2 & 1 & & \\ & & \ddots & \ddots & \\ & & & \rho^{g-1} & 1 \end{pmatrix},$$

(2.4)

where $\rho = e^{2\pi i/g}$. In addition, there is a cyclic permutation symmetry $Z_{g}^{(C)}$ among these modes, i.e.

$$C = \begin{pmatrix} 0 & 1 & 0 & 0 & \cdots & 0 \\ 0 & 0 & 1 & 0 & \cdots & 0 \\ & & \ddots & \ddots & \ddots & \ddots \\ 1 & & & & \cdots & 0 \end{pmatrix}.$$  

(2.5)

Furthermore, these elements do not commute each other,

$$CZ = \rho ZC.$$  

(2.6)

Thus, this flavor symmetry includes another $Z_g'$ symmetry, which is represented by

$$Z' = \begin{pmatrix} \rho & & & \\ & \ddots & & \\ & & \ddots & \\ & & & \rho \end{pmatrix}.$$  

(2.7)

Then, these would generate the non-Abelian flavor symmetry, $(Z_g \times Z_g') \rtimes Z_g^{(C)}$.

For example, when $g = 2$ and $g = 3$, the symmetries correspond to $D_4$ and $\Delta(27)$. In addition, when the totally D-brane system has the $Z_2$ reflection symmetry $P$ between $i$-th mode and $(g - i)$-th mode the $\Delta(27)$ symmetry for $g = 3$ is enhanced into $\Delta(54)$ [13].

Similarly, we can discuss models with more than two sets of D-branes. For example, suppose that we add $N_c$ stacks of D-branes to the above system, and that their intersecting numbers satisfy $G.C.D.(I_{ab}^{(i)}, I_{ac}^{(i)}, I_{bc}^{(i)}) = d$. Then, this model has the discrete flavor symmetry $(Z_d \times Z_d') \rtimes Z_d^{(C)}$.

The above result is applicable to intersecting D-brane models on orientifolds through simple extension. Also, we can extend our discussions to orbifold cases [13, 14, 15].

Since magnetized D-brane models are T-duals to intersecting D-brane models, the magnetized D-brane models also have the same discrete flavor symmetries. For example, we start with $(N_a + N_b)$ stacks of D9-branes on $T^6$. Then, we introduce the magnetic flux...
on $T^2_i$ along $U(1)_a$ and $U(1)_b$ directions in $U(N_a + N_b)$ as
\begin{equation}
F^{(i)} = 2\pi \begin{pmatrix}
M_{a}^{(i)} & & & \\
& \ddots & & \\
& & M_{a}^{(i)} & \\
& & & M_{b}^{(i)}
\end{pmatrix},
\end{equation}
where $M_{a}^{(i)}$ and $M_{b}^{(i)}$ are integers. This magnetic flux background breaks the gauge group $U(N_a + N_b)$ into $U(N_a) \times U(N_b)$. The gaugino fields in the off-diagonal part correspond to the $(N_a, \bar{N}_b)$ bi-fundamental matter fields under the unbroken $U(N_a) \times U(N_b)$ gauge symmetry. Zero-modes with such representation appear in this model, and the number of zero-modes on $T^2_i$ is equal to $M_{a}^{(i)} - M_{b}^{(i)}$. When we denote $M_{a}^{(i)} - M_{b}^{(i)} = g$, this magnetized D-brane model leads to the same discrete flavor symmetry, $(Z_g \times Z'_g) \rtimes Z_2^{(C)}$ as the above intersecting D-brane model.

## 3 Discrete anomalies

In this section, we study anomalies of discrete flavor symmetries.

### 3.1 $U(1)$ anomalies

Before studying anomalies of discrete flavor symmetries, it is useful to review anomalies of $U(1)$ gauge symmetries. In this subsection, we give a brief review on $U(1)$ anomalies \[9,36\] (see also \[12,5\]).

First of all, we consider the torus compactification. A D6-brane has a charge of RR 7-form $C_7$. The total charge should vanish in a compact space. That leads to the following tadpole cancellation condition,
\begin{equation}
\sum_{a} N_a [\Pi_a] = 0.
\end{equation}

The $SU(N_a)^3$ anomaly coefficient is calculated in the intersecting D-brane models by
\begin{equation}
A_a = \sum_{b} I_{ab} N_b,
\end{equation}
because there are $I_{ab}$ matter fields with $(N_a, \bar{N}_b)_{(1,-1)}$ for $I_{ab} > 0$ and $|I_{ab}|$ matter fields with $(\bar{N}_a, N_b)_{(-1,1)}$ for $I_{ab} < 0$. However, the tadpole cancellation condition leads to
\begin{equation}
[\Pi_a] \cdot \sum_{b} N_b [\Pi_b] = 0.
\end{equation}
That implies that $A_a = 0$, that is, anomaly free.

The $U(1)_a \times SU(N_b)^2$ mixed anomaly coefficient is obtained by

$$A_{ab} = N_a I_{ab}. \tag{3.4}$$

This anomaly is not always vanishing. However, this anomaly can always be canceled by the Green-Schwarz mechanism, where an axion shifts under the $U(1)$ gauge transformation and the anomalous $U(1)$ gauge boson becomes massive.

The $U(1)$-gravity$^2$ anomaly coefficient is obtained by

$$A_{a-\text{grav}} = N_a \sum_b I_{ab} N_b. \tag{3.5}$$

This anomaly is always vanishing when the tadpole cancellation condition is satisfied.

Next, we review on anomalies for the orientifold compactification. That is, we introduce $O_6$-branes along the direction $\prod_i [a_i]$. The system must be symmetric under the $Z_2$ reflection, $y_i \rightarrow -y_i$. In this case, we have to introduce a mirror $D_6$-branes with the winding number $(n^i_a, -m^i_a)$ corresponding to $(n^i_a, m^i_a)$. The $O_6$-brane has $(-4)$ times as RR charge as a $D_6$-brane. Then, the RR-tadpole cancellation condition requires

$$\sum_a N_a ([\Pi_a] + [\Pi_{a'}]) - 4[\Pi_{O6}] = 0. \tag{3.6}$$

$$\sum_{a \neq b} N_a [\Pi_b] \cdot ([\Pi_a] + [\Pi_{a'}]) + N_b [\Pi_b] \cdot [\Pi_{b'}] - 4[\Pi_b] \cdot [\Pi_{O6}] = 0. \tag{3.7}$$

In addition to $I_{ab}$ families of $(N_a, \bar{N}_b)_{(1,-1)}$ matter fields, there appear $I_{ab'}$ families of $(N_a, N_b)_{(1,1)}$ matter fields. Moreover, there appear matter fields with symmetric and asymmetric representations under $U(N_a)$ with charge 2. Their numbers are obtained by

$$\#_{a,\text{asymm}} = \frac{1}{2} ([\Pi_a] \cdot [\Pi_{a'}] - [\Pi_a] \cdot [\Pi_{O6}]) + [\Pi_a] \cdot [\Pi_{O6}], \tag{3.8}$$

$$\#_{a,\text{symm}} = \frac{1}{2} ([\Pi_a] \cdot [\Pi_{a'}] - [\Pi_a] \cdot [\Pi_{O6}]). \tag{3.9}$$

In this case, we can show that the $SU(N_a)^3$ anomaly coefficient always vanishes when the RR-tadpole cancellation condition is satisfied, similarly to in the torus compactification. Also, the $U(1)_a - SU(N_b)^2$ anomaly coefficient is not always vanishing, but such anomaly can be canceled by the Green-Schwarz mechanism.

Finally, the $U(1)_a - \text{gravity}^2$ anomaly coefficient is obtained by

$$A_{a-\text{grav}} = \prod_{b \neq} N_a N_b ([\Pi_a] \cdot [\Pi_b] + [\Pi_a] \cdot [\Pi_{b'}]) + 2 N_a(N_a - 1) \frac{\#_{a,\text{asymm}}}{2} + 2 \frac{N_a(N_a + 1)}{2} \#_{a,\text{symm}} = 3N_a [\Pi_a] \cdot [\Pi_{O6}]. \tag{3.10}$$

This does not always vanish, but such anomaly can be canceled by the Green-Schwarz mechanism.
3.2 Discrete anomalies

In the gauge theory with the gauge group \( G \) and the Abelian discrete symmetry \( Z_N \), the \( Z_N - G^2 \) mixed anomaly coefficient is calculated by [37, 38, 29, 2],

\[
A_{Z_N-G^2} = \sum_m q^{(m)} T_2(R^{(m)}),
\]

where the summation of \( m \) is taken over fermions with \( Z_N \) charges \( q^{(m)} \) and the representation \( R^{(m)} \) under \( G \). Here, \( T_2(R^{(m)}) \) denotes the Dynkin index and we use the normalization such that \( T_2 = 1/2 \) for the fundamental representation of \( SU(N) \). When the following condition is satisfied [37, 38, 29, 2],

\[
\sum_m q^{(m)} T_2(R^{(m)}) = 0 \pmod{N/2},
\]

the \( Z_N \) symmetry is anomaly-free. Similarly, we can calculate the \( Z_N \)-gravity\(^2 \) anomaly coefficient by \( \text{Tr}q^{(m)} \). If \( \text{Tr}q^{(m)} = 0 \pmod{N/2} \), \( Z_N \) is anomaly-free. For example, \( Z_2 \) symmetry is always anomaly-free.

Each generator of non-Abelian discrete symmetries corresponds to an Abelian symmetry. Thus, if each Abelian generator of non-Abelian discrete flavor symmetry satisfies the above anomaly-free condition, the total non-Abelian symmetry is anomaly-free. When some discrete Abelian symmetries are anomalous, the total non-Abelian discrete symmetry is broken, and the subgroup, which does not include anomalous generators, remains unbroken.

In the non-Abelian discrete symmetry, there appear multiplets and each generator is represented by a matrix, \( M \). When \( \det M = 1 \), the corresponding Abelian discrete symmetry is always anomaly-free. Only multiplets with \( \det M \neq 1 \) can contribute to anomalies. Since we have \( \det Z' = 1 \), the corresponding \( Z'_g \) symmetry is always anomaly-free. On the other hand, we find \( \det Z = \det C = 1 \) for \( g = \text{odd} \) and \( \det Z = \det C = -1 \) for \( g = \text{even} \). That means that the discrete flavor symmetry \( (Z_g \times Z'_g) \times Z_g^{(C)} \) is always anomaly-free for \( g = \text{odd} \), but \( Z_g \) and \( Z_g^{(C)} \) can be anomalous for \( g = \text{even} \). In particular, their \( Z_2 \) parts are anomalous. One has to check the anomaly-free condition for such \( Z_2 \) part for \( Z_g \) and \( Z_g^{(C)} \). For example, the \( \Delta(27) \) flavor symmetry for \( g = 3 \) is always anomaly-free. However, \( Z_2 \) subgroups of \( D_4 \) for \( g = 2 \) corresponding to the following elements,

\[
\begin{pmatrix}
1 & 0 \\
0 & -1
\end{pmatrix}, \quad \begin{pmatrix}
0 & 1 \\
1 & 0
\end{pmatrix},
\]

(3.13)
can be anomalous.

First, we discuss the torus compactification. For simplicity, we concentrate on the flavor symmetry appearing the first torus \( T^2_1 \) and we assume that all of intersecting numbers on \( T^2_1, T^1_{ab} \), are even. Thus, the total flavor symmetry includes the \( Z_2 \) symmetry as well as \( Z_2^{(C)} \), which can be anomalous. Also, we assume that there appears a trivial symmetry
from the other $T_2^2 \times T_3^2$. Now, let us examine the $Z_2 - SU(N_a)^2$ anomaly. There are $I_{ab}$ bi-fundamental matter fields with the representation $(N_a, \bar{N}_b)$. A half of $I_{ab}$ matter fields have even $Z_2$ charge and the others have odd $Z_2$ charge. The anomaly coefficient of $Z_2 - SU(N_a)^2$ anomaly can be written by

$$\sum_b \frac{I_{ab}}{2} N_b \frac{1}{2}.$$  \hspace{1cm} (3.14)

It vanishes because the tadpole cancellation condition, $\sum_b I_{ab} N_b = 0$. Thus, this $Z_2$ symmetry is anomaly-free on the torus compactification. Since only this $Z_2$ symmetry can be anomalous and the others are always anomaly-free, the non-Abelian flavor symmetries $(Z_g \times Z_g') \times Z_g^{(c)}$ are always anomaly-free in the torus compactification.

Next, we study the orientifold compactification. Similarly, we can calculate the $Z_2 - SU(N_a)^2$ anomaly coefficient,

$$\sum_{b \neq a} \left( \frac{I_{ab}}{2} N_b + \frac{I_{ab'}}{2} N_{b'} \right) \frac{1}{2} + \frac{N_a - 2}{4} \#_{a,\text{asym}} + \frac{N_a + 2}{4} \#_{a,\text{symm}}$$

$$= \frac{[\Pi_a] \cdot [\Pi_{O6}]}{2}$$  \hspace{1cm} (3.15)

That is not always vanishing, but it is proportional to the $U(1)_a^{\text{grav}}$ anomaly. Thus, this anomaly could be canceled when one requires the axion shift under the $Z_2$ transformation, which is related with the axion shift under $U(1)_a$. In addition, when D6$_a$ branes are parallel to the O6-branes, $Z_2 - SU(N_a)^2$ anomaly coefficient is always vanishing.

4 Majorana neutrino masses

In the previous section, we have studied on anomalies of discrete flavor symmetries. Certain symmetries are anomaly-free. For example, the $\Delta(27)$ flavor symmetry is anomaly-free. Anomalous symmetries can be broken by non-perturbative effects. There is no guarantee that anomaly-free symmetries are not broken by stringy non-perturbative effects. In this section, we consider D-brane instanton effects as concrete non-perturbative effects. We study which form of right-handed Majorana neutrino mass matrix can be generated by D-brane instanton effects. Indeed, following [31, 32, 33], we study the sneutrino mass matrix assuming that the neutrino mass matrix has the same form and supersymmetry breaking effects are small.

4.1 Neutrino mass matrix

Here, we study right-handed Majorana neutrino masses, which can be generated by D-brane instanton effects. We assume that $g$ families of right-handed neutrinos $\nu_R^a$ appear by intersections between D6$_c$-brane and D6$_d$ branes, and that their intersecting numbers are equal to $I_{cd}^{(i)} = g$ for the $i$-th $T^2$ and $I_{cd}^{(j)} = 1$ for the other tori. For the moment,
let us concentrate on the three-generation model, \( I_{cd} = 3 \), which can be obtained by \((I_{cd}^{(1)}, I_{cd}^{(2)}, I_{cd}^{(3)}) = (3, 1, 1)\), where the underline denotes all the possible permutations. We consider D2-brane instanton, which wraps one-cycle of each \( T^2 \) of \( T^6 = T^2 \times T^2 \times T^2 \). We call it \( D2_M \)-brane. It intersects with \( D6_e \) brane and \( D6_d \) brane. At these intersecting points, zero-modes \( \alpha_i \) and \( \gamma_j \) appear and their numbers are obtained by \( I_{Mc} \) and \( I_{dM} \). Only if there are two zero-modes for both \( \alpha_i \) and \( \gamma_j \) the neutrino masses can be generated by D2-brane instanton effect \([31, 32, 33]\),

\[
M \int d^2 \alpha d^2 \gamma e^{-d_{ij}^\alpha \alpha_i \nu_R^\alpha \gamma_j} = M c_{ab},
\]

\[
c_{ab} = \nu_R^a \nu_R^b (\varepsilon_{ij} \varepsilon_{kl} d_{ak}^i d_{bj}^j),
\]

where the mass scale \( M \) would be determined by the string scale \( M_{st} \) and the instanton world volume \( V \) as \( M = M_{st} e^{-V} \). Here, \( d_{ij}^\alpha \) is the 3-point coupling coefficient among \( \alpha_i \), \( \nu_R^\alpha \) and \( \gamma_j \) \([19]\), which we show explicitly in the next subsection. The 3-point coupling coefficient \( d_{ij}^\alpha \) can be written by \( d_{ij}^\alpha = d_{ij}^{\alpha} d_{ij}^{\beta} d_{ij}^{\gamma} \), where \( d_{ij}^\alpha \) is the contribution from the \( k \)-th torus. In addition, when \( \alpha_i \), \( \gamma_j \), or \( \nu^a \) are localized at a single intersecting point on the \( k \)-th torus, we omit the indexes such as \( d_{ij}^{\alpha} \), \( d_{ij}^{\beta} \), or \( d_{ij}^{\gamma} \).

We have to take into account all of the possible \( D2_M \)-brane configurations, which can generate the above neutrino mass terms. One can obtain two zero-modes of \( \alpha_i \) and \( \gamma_j \) for the \( D2_M \)-brane set corresponding to Sp(2) or U(2) gauge group with the intersecting numbers \( |I_{Mc}| = |I_{Md}| = 1 \) \([34]\) or a single \( D2_M \)-brane with the intersecting numbers, \( |I_{Mc}| = |I_{Md}| = 2 \).

When the \( D2_M \)-brane set corresponds to the Sp(2) or U(2) brane, the zero-modes, \( \alpha_i \) and \( \gamma_j \), are doublets and the gauge invariance allows the certain couplings, say \( \alpha_i \) and \( \gamma_i \), but not \( \alpha_i \) and \( \gamma_j \) for \( i \neq j \). When \( I_{Mc} = I_{dM} = 1 \), the following form of the Majorana mass is generated,

\[
\int d^2 \alpha d^2 \gamma e^{-d_{ij}^{11} \alpha_i \nu_R^1 \gamma_j - d_{ij}^{22} \alpha_i \nu_R^2 \gamma_j} = \nu_R^a \nu_R^b d_{ij}^{11} d_{ij}^{22}.
\]

More explicitly, the following form of mass matrix is obtained \([34]\),

\[
M_{eab} = \begin{pmatrix}
   d_{ij}^{11} d_{ij}^{22} & d_{ij}^{11} d_{ij}^{22} & d_{ij}^{11} d_{ij}^{22} \\
   d_{ij}^{11} d_{ij}^{22} & d_{ij}^{11} d_{ij}^{22} & d_{ij}^{11} d_{ij}^{22} \\
   d_{ij}^{11} d_{ij}^{22} & d_{ij}^{11} d_{ij}^{22} & d_{ij}^{11} d_{ij}^{22}
\end{pmatrix}.
\]

This Majorana mass matrix has the rank one. However, we have to take into account all of the \( D2_M \)-brane configurations, that is, the position of \( D2_M \)-brane sets. Thus, we integrate over the position of the \( D2_M \)-brane sets. Such integration over the \( D2_M \)-brane position would recover the cyclic permutation symmetry, \( Z_{g=3}^{(C)} \). Then, we would obtain the following form of Majorana neutrino mass matrix,

\[
M = \begin{pmatrix}
   A & B & B \\
   B & A & B \\
   B & B & A
\end{pmatrix}.
\]
We will show this form by an explicit calculation in the next subsection. As a result, there remains the cyclic permutation symmetry, \( Z_{g=3} \), unbroken, but \( Z_{g=3} \) and \( Z'_{g} \) symmetries are broken by D-brane instanton effects, which generate the Majorana neutrino masses. This form also has the \( Z_2 \) reflection symmetry \( P \). Thus, if the full D-brane system has the \( Z_2 \) reflection symmetry, the symmetry is enhanced into \( S_3 \).

Similarly, we can study a single \( D2_M \)-brane with the intersecting numbers, \(|I_{Mc}| = |I_{Md}| = 2\). There are two types of \( D2_M \)-brane instanton configurations leading to \(|I_{Mc}| = |I_{Md}| = 2\). In one type, we have the configuration with \(|I_{Mc}^{(j)}| = |I_{Md}^{(k)}| = 2\) for \( j \neq k \), and in the other type we have the configuration with \(|I_{Mc}^{(j)}| = |I_{Md}^{(i)}| = 2\).

In the first case with \(|I_{Mc}^{(j)}| = |I_{Md}^{(k)}| = 2\) for \( j \neq k \), let us set e.g. \( j = 1 \) and \( k = 2 \). Then, the Yukawa coupling \( d_{ij}^a \) can be written by

\[
\varepsilon_{ij} \varepsilon_{kl} d_{ij}^a d_{kl}^b = \varepsilon_{ij} \varepsilon_{kl} d_{i1}^a d_{k2}^b d_{3j}^d d_{2k}^e d_{3j}^f d_{3k}^e. \tag{4.5}
\]

However, this vanishes identically. We obtain the same result for \(|I_{Mc}^{(j)}| = |I_{Md}^{(k)}| = 2\) with \( j \neq k \), when \((I_{cd}^{(1)}, I_{cd}^{(2)}, I_{cd}^{(3)}) = (3, 1, 1)\).

On the other hand, if a single \( D2_M \)-brane configuration with \(|I_{Mc}^{(j)}| = |I_{Md}^{(j)}| = 2\) is possible, we obtain the non-vanishing neutrino mass matrix \( M_{cab} \). Then, when we integrate over the position of the \( D2_M \)-brane instanton, we would obtain the same results as Eq.\( (4.4) \). Thus, the cyclic permutation symmetry \( Z_{g=3}^{(C)} \) is recovered.

This result can be extended for models with \( g \) flavors of neutrinos. When we take into account all of the possible D-brane instanton configurations, we would realize the neutrino mass matrix \( M_{cab} \) with the cyclic permutation symmetry \( Z_{g}^{(C)} \), i.e.

\[
c_{ab} = c_{a'b'} \quad \text{for} \quad a' = a + 1, \ b' = b + 1. \tag{4.6}
\]

Also the mass matrix is symmetric, i.e. \( c_{ab} = c_{ba} \). For example, we obtain

\[
c_{ab} = \begin{pmatrix} A & B \\ B & A \end{pmatrix}, \tag{4.7}
\]

for \( g = 2 \) and

\[
c_{ab} = \begin{pmatrix} A & B & B' & B \\ B & A & B' & B \\ B' & B & A & B \\ B & B' & B & A \end{pmatrix}, \tag{4.8}
\]

for \( g = 4 \). It is found that the D-brane instantons break \( Z_{g}^{'} \) into \( Z_2 \) if \( g \) is even. Otherwise, the \( Z_{g}^{'} \) symmetry as well as the \( Z_{g} \) symmetry is completely broken. However, the cyclic permutation symmetry remains.

\[\text{3 These forms also have the } Z_2 \text{ reflection symmetry.}\]
We have studied the neutrino mass matrix by assuming that the neutrino and sneutrino have the same mass matrix and supersymmetry breaking effect is small [31, 32, 33]. The important point to derive our result is the cyclic permutation symmetry. Thus, we would obtain the same result if the D-brane instantons do not break such a symmetry but supersymmetry is broken.

4.2 Explicit computation

Here, we discuss the Majorana neutrino mass matrix by computing explicitly the three-generation models. We consider the D2-brane instanton corresponding to Sp(2) or U(2) gauge symmetry. Suppose that D6\textsubscript{c} and D6\textsubscript{d} branes have the intersecting number, I\textsubscript{cd} = 3, and at three intersecting points there appear three generations of right-handed neutrinos. We set (I\textsubscript{cd}, 1, 1), and I\textsubscript{Me} = I\textsubscript{dM} = 1. Because the right-handed neutrinos are localized at different points from each other on the first torus, only the first torus is important for the flavor symmetry. Thus, we concentrate on the first torus for computations on Yukawa couplings and Majorana masses. We also omit the index corresponding to the k-torus.

There are three generations of $\nu_a$ and we here label their flavor index as $a = 0, 1, 2$. Also there are two-zero modes, $\alpha_i$ and $\gamma_j (i, j = 1, 2)$, but note that these indexes $i, j$ correspond to the doublets under Sp(2) or U(2) and the intersecting numbers, I\textsubscript{cM}, and I\textsubscript{Md}, are equal to one, I\textsubscript{cM} = I\textsubscript{Md} = 1.

Suppose that there are three fields $\phi_a$, $\chi_{i'}$ and $\chi_{j'}$ with the ”flavor numbers”, $a = 0$, $\cdots$, $I\textsubscript{cd} - 1$, $i' = 0$, $\cdots$, $I\textsubscript{dM} - 1$, and $j' = 0$, $\cdots$, $I\textsubscript{Mc} - 1$, where $I\textsubscript{cd}$, $I\textsubscript{dM}$, and $I\textsubscript{Mc}$ are the corresponding intersecting numbers on the torus. In this case, the 3-point couplings $d_{a}^{i'j'}$ among three fields can be calculated by [19]

$$d_{a}^{i'j'} = C \sum_{\ell \in \mathbb{Z}} \exp \left( -\frac{A_{a{i'j'}}(\ell)}{2\pi \alpha'} \right), \quad (4.9)$$

where $C$ is a flavor-independent constant due to quantum contributions and

$$A_{a{i'j'}}(\ell) = \frac{1}{2} A |I_{cd}I_{dM}I_{Mc}| \left( \frac{a}{I_{cd}} + \frac{i'}{I_{dM}} + \frac{j'}{I_{Mc}} + \frac{\varepsilon}{I_{dM}I_{Mc}} + \ell \right)^2, \quad (4.10)$$

and $A$ denotes the area of the first torus. Here, $\varepsilon$ denotes the position of D2\textsubscript{M}-brane on the first torus and we normalize $\varepsilon$ such that $\varepsilon$ varies $[0, 1]$ on the torus. Note that this coupling corresponds to the contribution on the first torus, which determines the flavor structure, but we have omitted the index corresponding to the first torus.

By using the $\vartheta$-function,

$$\vartheta \left[ \begin{array}{c} a \\ b \end{array} \right] (\nu, \tau) = \sum_{\ell \in \mathbb{Z}} \exp \left[ \pi i (a + \ell)^2 \tau + 2\pi i (a + \ell) (\nu + b) \right], \quad (4.11)$$

we can write

$$d_{a}^{i'j'} = C \vartheta \left[ \begin{array}{c} a \\ I_{cd} + i' \\ I_{dM} + j' \\ I_{Mc} + \varepsilon \\ 0 \end{array} \right] \left( 0, i A |I_{cd}I_{dM}I_{Mc}| \right). \quad (4.12)$$
Our model corresponds to \( a = 0, 1, 2, I_{cd} = 3, i' = j' = 0, I_{dM} = I_{Mc} = 1 \). In the above model, the 3-point couplings among \( \nu_a, \alpha_i, \) and \( \gamma_j \) are written by

\[
d_{ij}^a \delta_{ij} \vartheta \left[ \begin{array}{c} -\frac{a}{3} + \epsilon \\ 0 \end{array} \right] \left( 0, \frac{3iA}{4\pi^2\alpha'} \right).
\] (4.13)

Recall again that the indexes \( i \) and \( j \) of \( \alpha_i \) and \( \gamma_j \) are doublet indexes under \( \text{Sp}(2) \) or \( \text{U}(2) \).

Using this, the matrix \( c_{ab} \) is written by the integration of the position \( \epsilon \) over \([0, 1]\),

\[
c_{ab} = \int_0^1 d\epsilon \vartheta \left[ \begin{array}{c} -\frac{a}{3} + \epsilon + \frac{m}{2} \\ 0 \end{array} \right] \left( 0, \frac{3iA}{2\pi^2\alpha'} \right)
\]

\[
= \int_0^1 d\epsilon \sum_{m=1}^2 \vartheta \left[ \begin{array}{c} -\frac{a}{3} - \frac{b}{6} + \epsilon + \frac{m}{2} \\ 0 \end{array} \right] \left( 0, \frac{3iA}{2\pi^2\alpha'} \right)
\]

\[
\times \vartheta \left[ \begin{array}{c} -\frac{a}{3} + \frac{b}{6} + \frac{m}{2} \\ 0 \end{array} \right] \left( 0, \frac{3iA}{2\pi^2\alpha'} \right).
\] (4.14)

We obtain

\[
\int_0^1 d\epsilon \vartheta \left[ \begin{array}{c} -\frac{a}{3} + \epsilon + \frac{m}{2} \\ 0 \end{array} \right] \left( 0, \frac{3iA}{2\pi^2\alpha'} \right)
\]

\[
= \int_0^1 d\epsilon \sum_{m=1}^2 \exp \left[ \pi i (-a/3 + \epsilon + m/2 + \ell)^2 \left( \frac{3iA}{2\pi^2\alpha'} \right) \right]
\]

\[
= \int_{-\infty}^{\infty} dx \exp \left[ -\frac{3A}{2\pi\alpha'} (x - a/3 + m/2)^2 \right]
\]

\[
= \frac{\sqrt{2\pi^2\alpha'}}{3A}.
\] (4.15)

Using it, the matrix elements \( c_{ab} \) can be computed as follows. It is found that the diagonal elements \( c_{aa} \) do not depend on \( a \) and they are written by

\[
c_{aa} = \frac{\sqrt{2\pi^2\alpha'}}{3A} \left( \vartheta \left[ \begin{array}{c} 0 \\ 0 \end{array} \right] \left( 0, \frac{3iA}{2\pi^2\alpha'} \right) + \vartheta \left[ \begin{array}{c} \frac{3}{3} \\ 0 \end{array} \right] \left( 0, \frac{3iA}{2\pi^2\alpha'} \right) \right).
\] (4.16)

Similarly, the off-diagonal elements are written by

\[
c_{01} = \frac{\sqrt{2\pi^2\alpha'}}{3A} \left( \vartheta \left[ \begin{array}{c} \frac{1}{3} \\ 0 \end{array} \right] \left( 0, \frac{3iA}{2\pi^2\alpha'} \right) + \vartheta \left[ \begin{array}{c} \frac{2}{3} \\ 0 \end{array} \right] \left( 0, \frac{3iA}{2\pi^2\alpha'} \right) \right),
\] (4.17)

\[
c_{02} = \frac{\sqrt{2\pi^2\alpha'}}{3A} \left( \vartheta \left[ \begin{array}{c} \frac{1}{6} \\ 0 \end{array} \right] \left( 0, \frac{3iA}{2\pi^2\alpha'} \right) + \vartheta \left[ \begin{array}{c} \frac{5}{6} \\ 0 \end{array} \right] \left( 0, \frac{3iA}{2\pi^2\alpha'} \right) \right),
\] (4.18)

\[
c_{12} = \frac{\sqrt{2\pi^2\alpha'}}{3A} \left( \vartheta \left[ \begin{array}{c} \frac{1}{6} \\ 0 \end{array} \right] \left( 0, \frac{3iA}{2\pi^2\alpha'} \right) + \vartheta \left[ \begin{array}{c} \frac{2}{3} \\ 0 \end{array} \right] \left( 0, \frac{3iA}{2\pi^2\alpha'} \right) \right).
\] (4.19)
However, we have the following formula of the \( \vartheta \)-function

\[
\vartheta \left[ \begin{array}{c} a \\ b \end{array} \right] (\nu, \tau) = \vartheta \left[ \begin{array}{c} a + 1 \\ b \end{array} \right] (\nu, \tau),
\]

(4.20)

\[
\vartheta \left[ \begin{array}{c} -a \\ 0 \end{array} \right] (0, \tau) = \vartheta \left[ \begin{array}{c} a \\ 0 \end{array} \right] (0, \tau).
\]

(4.21)

Then, we see that all of the off-diagonal elements are the same,

\[ c_{01} = c_{12} = c_{20}. \]

(4.22)

That is, we can realize the form (4.4) by explicit calculations. Figure 1 shows the ratio \( B/A = c_{12}/c_{aa} \) in (4.4) by varying the area \( 3A/2\pi^2\alpha' \).

![Figure 1: B/A v.s. 3A/2\pi^2\alpha'](image)

### 4.3 Phenomenological implication

Here we discuss phenomenological implication of our result. The Majorana mass matrix with the form (4.4) can be diagonalized by the following matrix,

\[
\begin{pmatrix}
\sqrt{2/3}c & 1/\sqrt{3} & -\sqrt{2/3}s \\
-1/\sqrt{6c} - 1/\sqrt{2s} & 1/\sqrt{3} & 1/\sqrt{6s} - 1/\sqrt{2c} \\
-1/\sqrt{6c} + 1/\sqrt{2s} & 1/\sqrt{3} & 1/\sqrt{6s} + 1/\sqrt{2c}
\end{pmatrix},
\]

(4.23)

where \( c = \cos \theta \) and \( s = \sin \theta \), and the eigenvalues are \( A - B, A + 2B \) and \( A - B \). That is, two eigenvalues are degenerate. This is because the mass matrix (4.4) has the additional \( Z_2 \) reflection symmetry \( P \) and the symmetry is enhanced into \( S_3 \). At any rate, this form of the mixing matrix is interesting, although the mass eigenvalues may be not completely realistic.
Suppose that the Dirac neutrino Yukawa couplings and charged lepton mass matrix are almost diagonal. Then, the lepton mixing matrix is obtained as the above matrix \( \text{[4.23]} \). That is the trimaximal matrix.

When \( s = 0 \), the above matrix becomes the tri-bimaximal mixing matrix. In field-theoretical model building, the tri-bimaximal mixing matrix can be obtained as follows \([1,2,3]\). We start with a larger flavor symmetry and break by vacuum expectation values of scalar fields. However, one assumes that \( Z_3 \) and \( Z_2 \) subsymmetries remain in the charged lepton or neutrino mass terms. Then, the tri-bimaximal mixing matrix can be realized. In our string theory, such a \( Z_3 \) symmetry is realized by geometrical symmetry of the cyclic permutation \( Z_3^C \), which can not be broken by the D-brane instanton effects, although other symmetries are broken.

We may need some corrections to realize the experimental values of neutrino masses. At least, the above results show that we can realize non-trivial mixing in the lepton sector even though our assumption above the Dirac masses can not be realized.

## 5 Conclusion and discussion

We have studied the flavor structure in intersecting D-brane models. We have discussed the anomalies of flavor symmetries. Certain symmetries are anomaly-free, and anomaly coefficients of discrete symmetries have the specific feature. We have studied the Majorana neutrino masses, which can be generated by D-brane instanton effects. It is found that the mass matrix form with the cyclic permutation symmetry can be realized by integrating over the position of D-brane instanton. That would lead to the interesting form of mixing angles. It is interesting to apply our results for more concrete models. We would study numerical analyses elsewhere.

In some models, there appear more than one pair of Higgs fields. Their masses would be generated by D-brane instanton effects. It would be important to study the form of such Higgs mass matrix. Also, some of Yukawa couplings may be generated by D-brane instanton effects. Thus, it would be important to extend our analysis to Higgs mass matrix and Yukawa matrices.

---

4The \( \Delta(27) \) flavor symmetry as well as \( \Delta(54) \) flavor symmetry may be useful to realize such a form.

5To resolve the degeneracy between two mass eigenvalues, it may be important to break the \( Z_2 \) reflection symmetry \( P \). The full D-brane system, i.e. the full Lagrangian of the low-energy effective field theory, may not have such \( Z_2 \) symmetry and the above degeneracy may be resolved by radiative corrections.
