Information Limits for Recovering a Hidden Community

Bruce Hajek Yihong Wu Jiaming Xu*
January 26, 2016

Abstract

We study the problem of recovering a hidden community of cardinality $K$ from an $n \times n$ symmetric data matrix $A$, where for distinct indices $i,j$, $A_{ij} \sim P$ if $i,j$ both belong to the community and $A_{ij} \sim Q$ otherwise, for two known probability distributions $P$ and $Q$ depending on $n$. If $P = \text{Bern}(p)$ and $Q = \text{Bern}(q)$ with $p > q$, it reduces to the problem of finding a densely-connected $K$-subgraph planted in a large Erdős-Rényi graph; if $P = \mathcal{N}(\mu,1)$ and $Q = \mathcal{N}(0,1)$ with $\mu > 0$, it corresponds to the problem of locating a $K \times K$ principal submatrix of elevated means in a large Gaussian random matrix. We focus on two types of asymptotic recovery guarantees as $n \to \infty$: (1) weak recovery: expected number of classification errors is $o(K)$; (2) exact recovery: probability of classifying all indices correctly converges to one. Under mild assumptions on $P$ and $Q$, and allowing the community size to scale sublinearly with $n$, we derive a set of sufficient conditions and a set of necessary conditions for recovery, which are asymptotically tight with sharp constants. The results hold in particular for the Gaussian case, and for the case of bounded log likelihood ratio, including the Bernoulli case whenever $p/q$ and $1-p/1-q$ are bounded away from zero and infinity. An important algorithmic implication is that, whenever exact recovery is information theoretically possible, any algorithm that provides weak recovery when the community size is concentrated near $K$ can be upgraded to achieve exact recovery in linear additional time by a simple voting procedure.

1 Introduction

Many modern datasets can be represented as networks with vertices denoting the objects and edges (sometimes weighted or labeled) encoding their pairwise interactions. An interesting problem is to identify a group of vertices with atypical interactions. In social network analysis, this group can be interpreted as a community with higher edge connectivities than the rest of the network; in microarray experiments, this group may correspond to a set of differentially expressed genes. To study this problem, we investigate the following probabilistic model considered in [18].

**Definition 1** (Hidden Community Model). Let $C^*$ be drawn uniformly at random from all subsets of $[n]$ of cardinality $K$. Given probability measures $P$ and $Q$ on a common measurable space, let $A$ be an $n \times n$ symmetric matrix with zero diagonal where for all $1 \leq i < j \leq n$, $A_{ij}$ are mutually independent, and $A_{ij} \sim P$ if $i,j \in C^*$ and $A_{ij} \sim Q$ otherwise.

In this paper we assume that we only have access to pairwise information $A_{ij}$ for distinct indices $i$ and $j$ whose distribution is either $P$ or $Q$ depending on the community membership; no direct observation about the individual indices is available (hence the zero diagonal of $A$). Two choices of $P$ and $Q$ arising in many applications are the following:

Xu is with the Simons Institute for the Theory of Computing, University of California, Berkeley, Berkeley, CA, jiamingxu@berkeley.edu.
• Bernoulli case: \( P = \text{Bern}(p) \) and \( Q = \text{Bern}(q) \) with \( p \neq q \). When \( p > q \), this coincides with the planted dense subgraph model studied in [32, 7, 12, 21, 33], which is also a special case of the general stochastic block model [26] with a single community. In this case, the data matrix \( A \) corresponds to the adjacency matrix of a graph, where two vertices are connected with probability \( p \) if both belong to the community \( C^* \), and with probability \( q \) otherwise. Since \( p > q \), the subgraph induced by \( C^* \) is likely to be denser than the rest of the graph.

• Gaussian case: \( P = \mathcal{N}(\mu, 1) \) and \( Q = \mathcal{N}(0, 1) \) with \( \mu \neq 0 \). This corresponds to a symmetric version of the submatrix localization problem studied in [37, 30, 10, 9, 31, 12, 11]. When \( \mu > 0 \), the entries of \( A \) with row and column indices in \( C^* \) have positive mean \( \mu \) except those on the diagonal, while the rest of the entries have zero mean.

Given the data matrix \( A \), the problem of interest is to accurately recover the underlying community \( C^* \). The distributions \( P \) and \( Q \) as well as the community size \( K \) depend on the matrix size \( n \) in general. For simplicity we assume that these model parameters are known to the estimator. The only assumptions on the community size \( K \) we impose are that \( K/n \) is bounded away from one, and, to avoid triviality, that \( K \geq 2 \). Of particular interest is the case of \( K = o(n) \), where the community size grows sublinearly.

We focus on the following two types of recovery guarantees. Let \( \xi \in \{0, 1\}^n \) denote the indicator of the community such that \( \text{supp}(\xi) = C^* \). Let \( \hat{\xi} = \hat{\xi}(A) \in \{0, 1\}^n \) be an estimator.

**Definition 2** (Exact Recovery). Estimator \( \hat{\xi} \) exactly recovers \( \xi \) if, as \( n \to \infty \), \( \mathbb{P}[\xi \neq \hat{\xi}] \to 0 \), where the probability is with respect to the randomness of \( \xi \) and \( A \).

**Definition 3** (Weak Recovery). Estimator \( \hat{\xi} \) weakly recovers \( \xi \) if, as \( n \to \infty \), \( d_H(\xi, \hat{\xi})/K \to 0 \) in probability, where \( d_H \) denotes the Hamming distance.

The existence of an estimator satisfying Definition 3 is equivalent to the existence of an estimator such that \( \mathbb{E}[d_H(\xi, \hat{\xi})] = o(K) \) (see Appendix A for a proof). Clearly, any estimator achieving exact recovery also achieves weak recovery; for bounded \( K \), exact and weak recovery are equivalent.

Intuitively, for a fixed network size \( n \), as the community size \( K \) decreases, or the distributions \( P \) and \( Q \) get closer together, the recovery problem becomes harder. In this paper, we aim to address the following question: From an information-theoretic perspective, computational considerations aside, what are the fundamental limits of recovering the community? Specifically, we derive sharp necessary and sufficient conditions in terms of the model parameters under which the community can be exactly or weakly recovered. These results serve as benchmarks for evaluating practical algorithms and aid us in understanding the performance limits of polynomial-time algorithms.

In addition to establishing information limits with sharp constants for general \( P \) and \( Q \), we identify the following algorithmic connection between weak and exact recovery: If exact recovery is information-theoretically possible and there is an algorithm for weak recovery, then in linear additional time we can obtain exact recovery based on the weak recovery algorithm. This suggests that if the information limit of weak recovery can be obtained in polynomial time, then so can exact recovery; conversely, if there exists a computational barrier that separates the information

---

1. The previously studied submatrix localization model (also known as noisy biclustering) deals with submatrices whose row and column supports need not coincide and the noise matrix is asymmetric consisting of iid entries throughout. Here we focus on locating principal submatrices contaminated by a symmetric noise matrix. Additionally, we assume the diagonal does not carry any information. If instead we assume nonzero diagonal with \( A_{ii} \sim \mathcal{N}(\mu, 1) \) if \( i \in C^* \) and \( A_{ii} \sim \mathcal{N}(0, 1) \) if \( i \notin C^* \), the results in this paper carry over with minor modifications explained in Remark 11.

2. Exact and weak recovery are called strong consistency and weak consistency in [34], respectively.
limit and the performance of polynomial-time algorithms for exact recovery, then weak recovery also suffers from such a barrier. To establish the connection, we apply a two-step procedure: the first step uses an estimator capable of weak recovery, even in the presence of a slight mismatch between \(|C^*|\) and \(K\), such as the maximum likelihood estimator (see Lemma 4); the second step cleans up the residual errors through a local voting procedure for each index. In order to ensure the first and second step are independent, we use a method which we call successive withholding. The method of successive withholding is to randomly partition the set of indices into a finite number of subsets. One at a time, one subset is withheld to produce a reduced set of indices, and an estimation algorithm is run on the reduced set of indices. The estimate obtained from the reduced set of indices is used to classify the indices in the withheld subset. The idea is to gain independence: the outcome of estimation based on the reduced set of indices is independent of the data between the withheld indices and the reduced set of indices, and the withheld subset is sufficiently small so that we can still obtain sharp constants. This method is mentioned in [14], and variations of it have been used in [14], [35], and [34].

1.1 Related Work

Previous work has determined the information limits for exact recovery up to universal constant factors for some choices of \(P\) and \(Q\). For the Bernoulli case, it is shown in [12] that if \(Kd(q\parallel p) - c\log K \to \infty\) and \(Kd(p\parallel q) \geq c\log n\) for some large constant \(c > 0\), then exact recovery is achievable via the maximum likelihood estimator (MLE); conversely, if \(Kd(q\parallel p) \leq c'\log K\) and \(Kd(p\parallel q) \leq c'\log n\) for some small constant \(c' > 0\), then exact recovery is impossible for any algorithms. Similarly, for the Gaussian case, it is proved in [30] that if \(K\mu^2 \geq c\log n\), then exact recovery is achievable via the MLE; conversely, if \(K\mu^2 \leq c'\log n\), exact recovery is impossible for any algorithms. To the best of our knowledge, there are only a few special cases where the information limits with \textit{sharp} constants are known:

- Bernoulli case with \(p = 1\) and \(q = 1/2\): It is widely known as the planted clique problem [27]. If \(K \geq 2(1 + \epsilon)\log_2 n\) for any \(\epsilon > 0\), exact recovery is achievable via the MLE; if \(K \leq 2(1 - \epsilon)\log_2 n\), then exact recovery is impossible. Despite an extensive research effort polynomial-time algorithms are only known to achieve exact recovery for \(K \geq c\sqrt{n}\) for any constant \(c > 0\) [3, 19, 16, 6, 18].

- Bernoulli case with \(p = a\log n/n\) and \(q = b\log n/n\) for fixed \(a, b\) and \(K = \rho n\) for a fixed constant \(0 < \rho < 1\). The recent work [20] finds an explicit threshold \(\rho^*(a,b)\), such that if \(\rho > \rho^*(a,b)\), exact recovery is achievable in polynomial-time via semi-definite relaxations of the MLE with probability tending to one; if \(\rho < \rho^*(a,b)\), any estimator fails to exactly recover the cluster with probability tending to one regardless of the computational costs. This conclusion is in sharp contrast to the computational barriers observed in the planted clique problem.

- The paper of Butucea et al. [9] gives sharp results for a Gaussian submatrix recovery problem similar to the one considered here – see Remark 7 for details.

While this paper focuses on information-theoretic limits, it complements other work investigating computationally efficient recovery procedures, such as convex relaxations [4, 5, 12, 20, 23], spectral methods [32], and message-passing algorithms [18, 33, 24, 22]. In particular, for both the Bernoulli and Gaussian cases:

- if \(K = \Theta(n)\), a linear-time degree-thresholding algorithm achieves the information limit of weak recovery (see [22, Appendix A] and [24, Appendix A]);
if $K = \omega(n/\log n)$, whenever information-theoretically possible, exact recovery can be achieved in polynomial time using semi-definite programming [23];

- if $K \geq \frac{n}{\log n}(1/(8e) + o(1))$ for Gaussian case and $K \geq \frac{n}{\log n}(\rho_{\text{BP}}(a/b) + o(1))$ for Bernoulli case,\(^3\) exact recovery can be attained in nearly linear time via message passing plus clean up [22, 24] whenever information-theoretically possible.

However, it is an open problem whether any polynomial time can achieve the respective information limit of weak recovery for $K = o(n)$, or exact recovery for $K \leq \frac{n}{\log n}(1/(8e) - \epsilon)$ in the Gaussian case and for $K \leq \frac{n}{\log n}(\rho_{\text{BP}}(a/b) - \epsilon)$ in the Bernoulli case, for any fixed $\epsilon > 0$.

The related work [33] studies weak recovery in the sparse regime of $p = a/n, q = b/n$, and $K = \kappa n$. In the iterated limit where first $n \to \infty$, and then $\kappa \to 0$ and $a, b \to \infty$, with $\lambda = \frac{\kappa^2(a-b)^2}{(1-\kappa)b}$ fixed, it is shown that a local algorithm, namely local belief propagation, achieves weak recovery in linear time if $\lambda e > 1$ and conversely, if $\lambda e < 1$, no local algorithm can achieve weak recovery. Moreover, it is shown that for any $\lambda > 0$, MLE achieves a recovery guarantee similar to weak recovery in Definition 3. In comparison, the sharp information limit for weak recovery identified in Corollary 1 below allows $p, q$ and $K$ to vary simultaneously with $n$ as $n \to \infty$.

Finally, we briefly compare the results of this paper to those of [1] and [34] on the planted bisection model (also known as the binary symmetric stochastic block model), where the vertices are partitioned into two equal-sized communities. First, a necessary and sufficient condition for weak recovery and a necessary and sufficient condition for exact recovery are obtained in [34]. In this paper, sufficient and necessary conditions, (7) and (8) in Theorem 1, are presented separately. These conditions match up except right at the boundary; we do not determine whether recovery is possible exactly at the boundary. The result for exact recovery in [1] is similar in that regard. Perhaps future work, based on techniques from [34], can provide a more refined analysis for the recovery problem at the boundary. Secondly, when recovery is information theoretically possible for the planted bisection problem, efficient algorithms are shown to exist in [1] and [34]. In contrast, for detecting or recovering a single community whose size is sublinear in the network size, there can be a significant gap between what is information theoretically possible and what can be achieved by existing efficient algorithms (see [3, 8, 31, 21, 33]). We turn instead to the MLE for proof of optimal achievability. Finally, this paper covers both the Gaussian and Bernoulli case (and other distributions) in a unified framework without assuming that the community size scales linearly with the network size.

### Notation

For any positive integer $n$, let $[n] = \{1, \ldots, n\}$. For any set $T \subseteq [n]$, let $|T|$ denote its cardinality and $T^c$ denote its complement. We use standard big $O$ notations, e.g., for any sequences $\{a_n\}$ and $\{b_n\}$, $a_n = \Theta(b_n)$ or $a_n \asymp b_n$ if there is an absolute constant $c > 0$ such that $1/c \leq a_n/b_n \leq c$. Let Binom($n, p$) denote the binomial distribution with $n$ trials and success probability $p$. Let $D(P || Q) = \mathbb{E}_P[\log \frac{dP}{dQ}]$ denotes the Kullback-Leibler (KL) divergence between distributions $P$ and $Q$. Let Bern$(p)$ denote the Bernoulli distribution with mean $p$ and $d(p || q) = D$(Bern$(p)$ || Bern$(q)$) = $p \log \frac{p}{q} + \tilde{p} \log \frac{\tilde{p}}{\tilde{q}}$, where $\tilde{p} \triangleq 1 - p$. Logarithms are natural and we adopt the convention $0 \log 0 = 0$. Let $\Phi(x)$ and $\bar{Q}(x)$ denote the cumulative distribution function (CDF) and complementary CDF of the standard normal distribution, respectively.

\(^3\)Here $\rho_{\text{BP}}(a/b)$ denotes a constant only depending on $a/b$. 

4
2 Overview of Main Results

2.1 Background on Maximum Likelihood Estimator and Assumptions

Given the data matrix \( A \), a sufficient statistic for estimating the community \( C^* \) is the log likelihood ratio (LLR) matrix \( L \in \mathbb{R}^{n \times n} \), where \( L_{ij} = \log \frac{dP}{dQ}(A_{ij}) \) for \( i \neq j \) and \( L_{ii} = 0 \). For \( S,T \subset [n] \), define

\[
e(S,T) = \sum_{(i<j)\in(S\times T)\cup(T\times S)} L_{ij}. \tag{1}\]

Let \( \hat{C}_{ML} \) denote the maximum likelihood estimation (MLE) of \( C^* \), given by:

\[
\hat{C}_{ML} = \arg \max_{C \subset [n]} \{ e(C,C) : |C| = K \}, \tag{2}
\]

which minimizes the error probability \( \mathbb{P}\{\hat{C} \neq C^*\} \) because \( C^* \) is equiprobable by assumption. Evaluating the MLE requires knowledge of \( K \). Computation of the MLE is NP hard for general values of \( n \) and \( K \) because certifying the existence of a clique of a specified size in an undirected graph, which is known to be an NP complete problem \([29]\), can be reduced to computation of the MLE. Thus, evaluating the MLE in the worst case is deemed computationally intractable. It is worth noting that the optimal estimator that minimizes the expected number of misclassified indices (Hamming loss) is the bit-MAP decoder \( \tilde{\xi} = (\tilde{\xi}_i) \), where \( \tilde{\xi}_i = \arg \max_{j \in \{0,1\}} \mathbb{P}[\xi = j | L] \).

Therefore, although the MLE is optimal for exact recovery, it need not be optimal for weak recovery; nevertheless, we choose to analyze MLE due to its simplicity and it turns out to be asymptotically optimal for weak recovery as well.

Our results require mild regularity conditions on the size of the hidden community \( K \) and on the pair of distributions, \( P \) and \( Q \). Specifically, for \( K \), it is assumed without further comment that

\[
\limsup_{n \to \infty} \frac{\log n}{n-K} < 1.
\]

This assumption implies that \( \frac{\log n}{n-K} \to 1 \), so in several asymptotic results \( \log n \) and \( \log(n-K) \) are interchangeable; we give preference to \( \log n \). Also, to avoid triviality, it is assumed throughout that \( K \geq 2 \).

To state the assumption on \( P \) and \( Q \) we introduce some standard notation associated with binary hypothesis testing based on independent samples. Throughout the paper we assume the KL divergences \( D(P\|Q) \) and \( D(Q\|P) \) are finite. In particular, \( P \) and \( Q \) are mutually absolutely continuous, and the likelihood ratio, \( \frac{dP}{dQ} \), satisfies \( \mathbb{E}_Q \left[ \frac{dP}{dQ} \right] = \mathbb{E}_P \left[ (\frac{dP}{dQ})^{-1} \right] = 1 \). Let \( L = \log \frac{dP}{dQ} \) denote the LLR. The likelihood ratio test for \( n \) observations and threshold \( n\theta \) is to declare \( P \) to be the true distribution if \( \sum_{k=1}^{n} L_k \geq n\theta \) and to declare \( Q \) otherwise. For \( \theta \in [-D(Q\|P), D(P\|Q)] \), the standard Chernoff bounds for error probability of this likelihood ratio test are given by:

\[
Q \left[ \sum_{k=1}^{n} L_k \geq n\theta \right] \leq \exp(-n\mathbb{E}_Q(\theta)) \tag{3}
\]
\[
P \left[ \sum_{k=1}^{n} L_k \leq n\theta \right] \leq \exp(-n\mathbb{E}_P(\theta)), \tag{4}
\]

where the log moment generating functions of \( L \) are denoted by \( \psi_Q(\lambda) = \log \mathbb{E}_Q[\exp(\lambda L)] \) and \( \psi_P(\lambda) = \log \mathbb{E}_P[\exp(\lambda L)] = \psi_Q(\lambda + 1) \) and the large deviations exponents are give by Legendre
transforms of the log moment generating functions:

\[ E_Q(\theta) = \psi_Q^*(\theta) \triangleq \sup_{\lambda \in \mathbb{R}} \lambda \theta - \psi_Q(\lambda), \quad E_P(\theta) = \psi_P^*(\theta) \triangleq \sup_{\lambda \in \mathbb{R}} \lambda \theta - \psi_P(\lambda) = E_Q(\theta) - \theta. \quad (5) \]

In particular, \( E_P \) and \( E_Q \) are convex functions. Moreover, since \( \psi_Q^*(0) = -D(Q\|P) \) and \( \psi_Q^*(1) = D(P\|Q) \), we have \( E_Q(-D(Q\|P)) = E_P(D(P\|Q)) = 0 \) and hence \( E_Q(D(P\|Q)) = D(P\|Q) \) and \( E_P(-D(Q\|P)) = D(Q\|P) \). Our regularity assumption on the pair \( P \) and \( Q \) is the following.

**Assumption 1.** There exists a constant \( C \) such that for all \( n \),

\[ \psi_Q''(\lambda) \leq C \min \{ D(P\|Q), D(Q\|P) \}, \quad \forall \lambda \in [-1, 1]. \quad (6) \]

In general, \( \psi_Q''(\lambda) = \psi_P''(\lambda - 1) = \text{var}_Q(\lambda) \), where \( Q_\lambda \) is the tilted distribution defined by \( dQ_\lambda = \exp(\lambda L - \psi_Q(\lambda))dQ \), so the point of Assumption 1 is to require these quantities for \( \lambda \in [-1, 1] \) to be bounded by a constant times the divergences. Assumption 1 is the strongest condition imposed on \( P \) and \( Q \) in this paper; several of the results hold under weaker assumptions described in Section 3, which are also weaker than sub-Gaussianity of the LLR.

Assumption 1 is fulfilled in the following cases:

1. Bounded LLR: Lemma 1 in Section 3 shows that Assumption 1 holds if \( L \) is bounded by a constant, which, in particular, holds in the Bernoulli case if both \( \xi_q \) and \( \xi_Q \) are bounded away from zero and infinity.

2. Gaussian case: In the Gaussian case \( P = N(\mu, 1), Q = N(0, 1) \), we have \( L(x) = \mu(x - \frac{1}{2}) \), \( D(P\|Q) = D(Q\|P) = \mu^2/2 \), \( \psi_Q(\lambda) = \frac{(\lambda^2 - \lambda)\mu^2}{2} \), \( E_Q(\theta) = \frac{1}{8}(\mu + 2\theta)^2 \) and \( E_P(\theta) = E_Q(-\theta) \). In particular, \( \psi_Q''(\lambda) \equiv \mu^2 \) so Assumption 1 holds with \( C = 2 \) regardless of how \( \mu \) varies with \( n \). More generally, for \( P \) and \( Q \) lying in the same exponential family, Appendix B provides a simple sufficient condition to verify Assumption 1.

### 2.2 Weak Recovery

The following theorem is our main result about weak recovery. It gives a sufficient condition and a matching necessary condition for weak recovery.

**Theorem 1.** Suppose Assumption 1 holds. If

\[ K \cdot D(P\|Q) \to \infty \quad \text{and} \quad \liminf_{n \to \infty} \frac{(K - 1)D(P\|Q)}{\log \frac{N}{K}} > 2, \quad (7) \]

then

\[ \mathbb{P}\{\|\hat{C}_{\text{ML}}\Delta C^*\| \leq 2K\epsilon\} \geq 1 - e^{-\Omega(K/\epsilon)}, \]

where \( \epsilon = 1/\sqrt{KD(P\|Q)} \).

If there exists \( \hat{\xi} \) such that \( \mathbb{E}[d_H(\xi, \hat{\xi})] = o(K) \), then

\[ K \cdot D(P\|Q) \to \infty \quad \text{and} \quad \liminf_{n \to \infty} \frac{(K - 1)D(P\|Q)}{\log \frac{N}{K}} \geq 2. \quad (8) \]

**Remark 1.** The assumption \( K \geq 2 \), implies \( K/2 \leq K - 1 \leq K \), so the first parts of (7) and (8) would have the same meaning if \( K \) were replaced by \( K - 1 \). In the special case of bounded LLR, the factor \( K - 1 \) in the second parts of (7) and (8) can be replaced by \( K \). This is because if \( \log \frac{dp}{dq} \) is bounded, so is \( D(P\|Q) \), and \( KD(P\|Q) \to \infty \) implies \( K \to \infty \) and hence also \( (K - 1)/K \to 1 \).
Corollary 1 (Weak recovery in Bernoulli case). Suppose the ratios \( \log \frac{p}{q} \) and \( \log \frac{\bar{p}}{\bar{q}} \) are bounded. If

\[
K \cdot d(p||q) \to \infty \quad \text{and} \quad \liminf_{n \to \infty} \frac{Kd(p||q)}{\log \frac{n}{K}} > 2,
\]

then weak recovery is possible. If weak recovery is possible, then

\[
K \cdot d(p||q) \to \infty \quad \text{and} \quad \liminf_{n \to \infty} \frac{Kd(p||q)}{\log \frac{n}{K}} \geq 2.
\]

Remark 2. Condition (10) is necessary even if \( \frac{p}{q} \to \infty \), but (9) alone is not sufficient without the assumption that \( p/q \) is bounded. This can be seen by considering the extreme case where \( K = n/2 \), \( p = 1/n \), and \( q = e^{-n} \). In this case, condition (9) is clearly satisfied; however, the subgraph induced by index in the cluster is an Erdős-Rényi random graph with edge probability \( 1/n \) which contains at least a constant fraction of isolated vertices with probability converging to one as \( n \to \infty \). It is not possible to correctly determine whether the isolated vertices are in the cluster, hence the impossibility of weak recovery.

Corollary 2 (Weak recovery in Gaussian case). If

\[
K\mu^2 \to \infty \quad \text{and} \quad \liminf_{n \to \infty} \frac{(K-1)\mu^2}{\log \frac{n}{K}} > 4,
\]

then weak recovery is possible. If weak recovery is possible, then

\[
K\mu^2 \to \infty \quad \text{and} \quad \liminf_{n \to \infty} \frac{(K-1)\mu^2}{\log \frac{n}{K}} \geq 4.
\]

2.3 Exact Recovery

The following theorem states our main result about exact recovery. It gives a sufficient condition and a matching necessary condition for exact recovery. Since exact recovery implies weak recovery, conditions from Theorem 1 naturally enter.

Theorem 2. Suppose Assumption 1 holds. If (7) and the following hold:

\[
\liminf_{n \to \infty} \frac{KE_Q \left( \frac{1}{K} \log \frac{P}{Q} \right)}{\log n} > 1.
\]

then the maximum likelihood estimator satisfies \( \mathbb{P}\{\hat{C}_{ML} = C^*\} \to 1 \).

If there exists an estimator \( \hat{C} \) such that \( \mathbb{P}\{\hat{C} = C^*\} \to 1 \), then (8) and the following hold:

\[
\liminf_{n \to \infty} \frac{KE_Q \left( \frac{1}{K} \log \frac{P}{Q} \right)}{\log n} \geq 1.
\]

Remark 3. In the special case of linear community size, i.e., \( K = \Theta(n) \), (13) and (14) can be simplified by replacing \( E_Q \left( \frac{1}{K} \log \frac{P}{Q} \right) \) by the Chernoff index between \( P \) and \( Q \) [13]:

\[
E_P(0) = E_Q(0) = \sup_{0 \leq \lambda \leq 1} -\log \int \frac{dP}{dQ} \lambda dQ \triangleq C(P, Q).
\]

To see this, note that in the definition \( E_Q(\theta) \) in (5) the supremum can be restricted to \( \lambda \in [0, 1] \) and hence \( E_Q(\theta) \leq E_Q(\theta + \delta) \leq E_Q(\theta) + \delta \) as long as \( -D(Q||P) \leq \theta \leq \theta + \delta \leq D(P||Q) \).
By (7), $\delta = \frac{1}{n} \log \frac{n}{\psi} \leq D(P \| Q)$ for all sufficiently large $n$. Hence, if the case of $K = \Theta(n)$, $C(P, Q) \leq E_Q \left( \frac{1}{n} \log \frac{n}{\psi} \right) \leq C(P, Q) + \Theta(\frac{1}{n})$, proving the claim. The Chernoff index $C(P, Q)$ gives the optimal exponent for decay of sum of error probabilities for the binary hypothesis testing problem in the large-sample limit.

**Corollary 3** (Exact recovery in Bernoulli case). Suppose $\log \frac{p}{q}$ and $\log \frac{q}{p}$ are bounded. If (9) holds, and

$$\liminf_{n \to \infty} \frac{K d(\tau^* || q)}{\log n} > 1,$$

where

$$\tau^* = \frac{\log \frac{q}{p} + \frac{1}{K} \log \frac{n}{\psi}}{\log \frac{q}{p}},$$

then exact recovery is possible. If exact recovery is possible, then (10) holds, and

$$\liminf_{n \to \infty} \frac{K d(\tau^* || q)}{\log n} \geq 1.$$

**Proof.** In the Bernoulli case, $E_P(\theta) = d(\alpha \| p)$ and $E_Q(\theta) = d(\alpha \| q)$, where $\alpha = (\theta + \log \frac{q}{p}) / \log \frac{q}{p}$. □

**Remark 4.** Consider the Bernoulli case in the regime

$$K = \frac{pn}{\log n}, \quad p = \frac{a \log^s n}{n}, \quad q = \frac{b \log^s n}{n},$$

where $s \geq 1$ is fixed, $\rho \in (0, 1)$ and $a > b > 0$. Let $I(x, y) \triangleq x - y \log (ex/y)$ for $x, y > 0$. Then the sharp recovery thresholds are determined by Corollaries 1 and 3 as follows: For any $\epsilon > 0$,

- For $s > 1$, if $\rho I(b, a) \geq \frac{(2+\epsilon)(s-1) \log \log n}{\log n}$, then weak recovery is possible; if $\rho I(b, a) \leq \frac{(2-\epsilon)(s-1) \log \log n}{\log n}$, then weak recovery is impossible. For $s = 1$, weak recovery is possible if and only if $\rho I(b, a) = \omega(\frac{1}{\log n})$.

- Assume $\rho, a, b$ are fixed constants. Let $\tau_0 = (a-b)/\log(a/b)$. Then exact recovery is possible if $\rho I(b, \tau_0) > 1$; conversely, if $\rho I(b, \tau_0) < 1$, then exact recovery is impossible, generalizing the previous results of [20, 2] for linear community size ($s = 1$). To see this, note that by definition, $\tau^* = (1 + o(1))\tau_0 \log^s n/n$, and thus $d(\tau^* || q) = (1 + o(1))I(b, \tau_0) \log^s n/n$.

**Remark 5.** The recent work [28] considered a generalized planted bisection model where $A_{ij} \sim P$ if $i, j$ are in the same community and $Q$ if otherwise. Their result applies to the following generalization of the Bernoulli distribution, where $P = (p_0, \ldots, p_m)$ and $Q = (q_0, \ldots, q_m)$ with

$$p_i = \frac{a_i \log n}{n}, \quad q_i = \frac{b_i \log n}{n}, \quad 1 \leq i \leq m$$

for some $m \geq 1$ and positive constants $a_i, b_i$, $1 \leq i \leq m$. For this family of distribution the LLR is bounded and hence Theorem 2 gives the sharp condition for recovering a single hidden community. Specifically, note that $\psi_Q(\lambda) = \left( \sum_{i=1}^m a_i b_i \lambda - a_i \lambda - b_i \lambda + o(1) \right) \log n$. Thus for $K = m$ with a fixed $\rho$, the sharp threshold of exact recovery is given by $\rho \sup_{0 < \lambda < 1} \left( \sum_{i=1}^m a_i \lambda + b_i \lambda - a_i b_i \lambda \right) > 1$. For $m = 1$ with $a_1 = a$ and $b_1 = b$, the optimal $\lambda$ is determined by $a b \lambda^2 = (a-b)/\log(a/b) = \tau_0$, and the sharp threshold of exact recovery simplifies to $\rho I(b, \tau_0) > 1$, recovering the result for the Bernoulli case given in Remark 4.
Corollary 4 (Exact recovery in Gaussian case). If (11) holds and
\[
\liminf_{n \to \infty} \frac{K \mu^2}{(\sqrt{2 \log n} + \sqrt{2 \log K})^2} > 1,
\]
then exact recovery is possible. If exact recovery is possible, then (12) holds and
\[
\liminf_{n \to \infty} \frac{K \mu^2}{(\sqrt{2 \log n} + \sqrt{2 \log K})^2} \geq 1.
\]
See Appendix C for a proof of Corollary 4.

Remark 6. Consider the Gaussian case in the regime
\[
K = \frac{\rho m}{\log^{s-1} n}, \quad \mu^2 = \frac{\mu_0^2 \log^s n}{n},
\]
where \(s \geq 1\) and \(\rho \in (0,1)\) are fixed constants. The critical signal strength that allows weak or exact recovery is determined by Corollaries 2 and 4 as follows: For any \(\epsilon > 0\),

- For \(s > 1\), if \(\mu_0 > (2 + \epsilon)\sqrt{\frac{(s-1) \log \log n}{\rho \log n}}\), then weak recovery is possible; conversely, if \(\mu_0 < (2 - \epsilon)\sqrt{\frac{(s-1) \log \log n}{\rho \log n}}\), then weak recovery is impossible. For \(s = 1\), weak recovery is possible if and only if \(\mu_0 = \omega\left(\frac{1}{\sqrt{\log n}}\right)\).

- If \(\mu_0 > \sqrt{\frac{8+\epsilon}{\rho}}\), then exact recovery is possible; conversely, If \(\mu_0 < \sqrt{\frac{8-\epsilon}{\rho}}\), then exact recovery is impossible.

Remark 7. Butucea et al. [9] considers the submatrix localization model with an \(n \times m\) submatrix with an elevated mean in an \(N \times M\) large Gaussian random matrix with independent entries, and gives sufficient conditions and necessary conditions, matching up to constant factors, for exact recovery, which are analogous to those of Corollary 4. Setting \((n,m,N,M)\) in [9, (2.3)] (sufficient condition for exact recovery of rectangular submatrix) equal to \((K,K,n,n)\) gives precisely the sufficient condition of Corollary 4 for exact recovery of a principal submatrix of size \(K\) from symmetric noise. This coincidence can be understood as follows. The nonsymmetric observations of [9, (2.3)] in the case of parameters \((K,K,n,n)\) yield twice the available information as the symmetric observation matrix we consider (diagonal observations excluded) while the amount of information required to specify a \(K \times K\) (not necessarily principal) submatrix of an \(n \times n\) matrix is twice the information needed to specify a principal one. The proof techniques of [9] are similar to ours, with the main difference being that we simultaneously investigate conditions for weak and exact recovery. Finally, the information limits of weak recovery for biclustering are established in [24, Section 4.1] based on modifications of the arguments in [9].

Remark 8. If \(K \leq n^{1/9}\), (11) implies (19), and thus (11) alone is sufficient for exact recovery; if \(K \geq n^{1/9}\), then (19) implies (11), and (19) alone is sufficient for exact recovery.

The reminder of the paper is organized as follows. Section 3 gives some preliminaries. Section 4 proves Theorem 1, pertaining to weak recovery, and Section 5 proves Theorem 2, pertaining to exact recovery. Additional results are introduced in Section 5, which highlight alternative sufficient and necessary conditions for exact recovery involving large deviation probabilities for sums of random variables, related to the voting procedure mentioned in the introduction.
3 On the Assumptions on P and Q

This section presents some conditions sufficient for Assumption 1, and some implications of Assumption 1.

Lemma 1 (Bounded LLR). If $|L| \leq B$ for some positive constant $B$, then Assumption 1 holds with $C = 2e^{5B}$.

Proof. First, some background. Let $\phi(y) = e^y - 1 - y$, which is nonnegative, convex, with $\phi(0) = \phi'(0) = 0$ and $\phi''(y) = e^y$. Thus for $|y| \leq B$, $e^{-B} \leq \phi''(y) \leq e^{B}$ and hence $\frac{e^{-B}y^2}{2} \leq \phi(y) \leq \frac{e^{B}y^2}{2}$.

Now to the proof. We begin by noticing that for all $\lambda \in [-1, 1]$,

$$\psi''_Q(\lambda) = \text{var}_{Q\lambda}(L) \leq \mathbb{E}_{Q\lambda}[L^2] = \frac{\mathbb{E}_Q[L^2 e^{\lambda L}]}{\mathbb{E}_Q[e^{\lambda L}]} \leq e^{2B} \mathbb{E}_Q[L^2].$$

In turn, using $y^2 \leq 2e^2 \phi(y)$ as shown above and recalling that $L = \log \frac{dP}{dQ}$, we have

$$\mathbb{E}_Q[L^2] \leq 2e^{B} \mathbb{E}_Q[\phi(L)] = 2e^{B} D(Q \mid P).$$

Combining the last two displayed equations yields $\psi''_Q(\lambda) \leq 2e^{3B} D(Q \mid P)$ for $\lambda \in [-1, 1]$. Abbreviate $\psi_Q$ by $\psi$. By a variation of the argument above, we have

$$\psi''(\lambda) = \text{var}_{Q\lambda}(L) \leq \mathbb{E}_{Q\lambda}[L^2] = \frac{\mathbb{E}_Q[L^2 e^{\lambda L}]}{\mathbb{E}_Q[e^{\lambda L}]} \leq e^{4B} \mathbb{E}_Q[L^2] \quad \text{if } \lambda \in [0, 2],$$

so that $\psi''(\lambda) \leq 2e^{5B} D(Q \mid P)$ for $\lambda \in [0, 2]$. Let $\psi$ denote the version of $\psi$ that would be obtained if the roles of $P$ and $Q$ were swapped. Then $\psi''(\lambda) \leq 2e^{5B} D(P \mid Q)$ for $\lambda \in [0, 2]$. Since $\psi$ and $\psi$ are related by reflection about $\lambda = 1/2$: $\psi(\lambda) \equiv \psi(1 - \lambda)$, we have $\psi''(\lambda) \leq 2e^{5B} D(P \mid Q)$ for $\lambda \in [-1, 1]$, completing the proof. \hfill \square

As shown in the proofs, Theorem 1 (weak recovery), and the sufficiency part of Theorem 2 (exact recovery) hold under assumptions somewhat weaker than Assumption 1; only the necessity part of Theorem 2 relies on Assumption 1. To clarify this subtlety, we introduce two successively weaker assumptions. We also provide a lemma showing that any of the assumptions imply the equivalence $D(P \mid Q) \asymp D(Q \mid P) \asymp C(P, Q)$.

Assumption 2. For some constant $C$:

$$\psi_P(\lambda) - D(P \mid Q)\lambda \leq \frac{CD(P \mid Q)}{2} \lambda^2, \quad \lambda \in [-1, 0] \quad (21)$$

$$\psi_Q(\lambda) + D(Q \mid P)\lambda \leq \frac{CD(Q \mid P)}{2} \lambda^2, \quad \lambda \in [-1, 1] \quad (22)$$

Remark 9. Assumption 2 is weaker than the assumption that $L$ is sub-Gaussian with scale parameter $D(P \mid Q)$ under $P$ and with scale parameter $D(Q \mid P)$ under $Q$. A sub-Gaussian assumption would correspond to requiring (21) and (22) to hold for all $\lambda \in \mathbb{R}$.

Assumption 3. For some constant $C$:

$$E_P((1 - \eta)D(P \mid Q)) \geq \frac{\eta^2}{2C} D(P \mid Q), \quad \eta \in [0, 1] \quad (23)$$

$$E_Q(-(1 - \eta)D(Q \mid P)) \geq \frac{\eta^2}{2C} D(Q \mid P), \quad \eta \in [0, 1]. \quad (24)$$
Lemma 2. Assumption 1 implies Assumption 2 which implies Assumption 3, with the same constant $C$ throughout. Any of these assumptions implies that:

$$\min\{D(P\|Q), D(Q\|P)\} \geq C(P, Q) \geq \frac{1}{2C} \max\{D(P\|Q), D(Q\|P)\},$$

(25)

and hence also that $D(P\|Q) \asymp D(Q\|P) \asymp C(P, Q)$.

Proof. Assumption 1 $\Rightarrow$ Assumption 2: Condition (21) is implied by Assumption 1 because $\psi_P'(0) = 0$, and $\psi_P'(0) = D(P\|Q)$, so by the integral form of Taylor’s theorem, $\psi_P(\lambda) - D(P\|Q)\lambda$ is $\lambda^2/2$ times a weighted average of $\psi''_P$ over the interval $[\lambda, 0]$ for $\lambda \in [-1, 0]$. Similarly, (22) is implied by Assumption 1 because $\psi_Q(\lambda) + D(Q\|P)\lambda$ is a weighted average of $\psi''_Q$ over the interval with endpoints 0 and $\lambda$, for $\lambda \in [-1, 1]$.

Assumption 2 $\Rightarrow$ Assumption 3: Since $\psi_P(-1) = \psi_Q(1) = 0$, either (21) or (22) imply that $C \geq 2$, which is achieved in the Gaussian case. Condition (21) implies

$$E_P((1 - \eta)D(P\|Q)) = \sup_{\lambda \in \mathbb{R}}(\lambda(1 - \eta)D(P\|Q) - \psi_P(\lambda))$$

$$\geq D(P\|Q)\sup_{\lambda \in \mathbb{R}}\left(-\lambda\eta - \frac{C\lambda^2}{2}\right) = \frac{\eta^2}{2C} D(P\|Q),$$

where the supremum is attained at $\lambda = -\frac{\eta^2}{C}$ which belongs to $[-1, 0]$ by the fact $C \geq 2$. So (21) implies (23). The proof that (22) implies (24) is similar.

Assumption 3 $\Rightarrow$ (25): Taking $\eta = 1$ in (23) and (24) we get $C(P, Q) \geq \frac{1}{2C} \max\{D(P\|Q), D(Q\|P)\}$. In the other direction, $D(P\|Q) = E_Q(D(P\|Q)) \geq E_Q(0) = C(P, Q)$ and, similarly, $D(Q\|P) \geq C(P, Q)$.

Recall the Chernoff upper bounds (3) and (4) on the probability of large deviations, which hold non-asymptotically for any sample size $n$ and any pair $P$ and $Q$. To prove the necessary condition for exact recovery, we need a lower bound with matching exponent. Such a result is well-known for fixed distributions. Indeed, the sharp asymptotics of large deviation is given by the Bahadur-Rao theorem (see, e.g., [17, Theorem 3.7.4]); however, this result is not applicable in the hidden community problem because both $P$ and $Q$ can vary with $n$. The following lemma provides a non-asymptotic information-theoretic lower bound (cf. [36, Theorem 11.1] and [15, Eq. (5.21), p. 167]):

Lemma 3. If $-D(Q\|P) \leq \gamma < \gamma + \delta \leq D(Q\|P)$, then

$$\exp(-nE_Q(\gamma)) \geq Q\left[\sum_{k=1}^n L_k > n\gamma \right] \geq \exp\left(-\frac{nE_Q(\gamma + \delta) + \log 2}{1 - \frac{1}{n\delta}\sup_{0 \leq \lambda \leq 1} \psi''_Q(\lambda)}\right).$$

(26)

Proof. The left inequality in (26) is the Chernoff bound (3); it remains to prove the right inequality. Let $E_n = \{\sum_{k=1}^n L_k > n\gamma\}$. For any $Q'$, the data processing inequality of KL divergence gives

$$d(Q'[E_n]\|Q[E_n]) \leq D(Q''\|Q'') = nD(Q'||Q).$$

Using the lower bound for the binary divergence $d(p\|q) = -h(p) + p\log\frac{1}{q} + (1 - p)\log\frac{1}{1-q} \geq -\log 2 + p\log\frac{1}{q}$ yields

$$d(Q'[E_n]\|Q[E_n]) \geq -\log 2 + Q'[E_n]\log\frac{1}{Q[E_n]},$$

11
so that

\[ Q[E_n] \geq \exp \left( \frac{-nD(Q'\|Q) - \log 2}{Q'[E_n]} \right). \]

For \( \lambda \in [0, 1] \), the tilted distribution \( Q_\lambda \) is given by \( dQ_\lambda = \frac{\exp(\lambda L)dQ}{\int P\exp(\lambda L)} = P^{\lambda Q_1^{1-\lambda}}. \) Then for any \( \alpha \in [-D(Q\|P), D(P\|Q)] \), there exists a unique \( \lambda \in [0, 1] \), such that \( \mathbb{E}_{Q_\lambda}[L] = \alpha \) and \( \mathbb{E}_Q(\alpha) = \psi^*_Q(\alpha) = D(Q_\lambda\|Q). \) Choosing \( \alpha = \gamma + \delta \) and \( Q' = Q_\lambda \), we have

\[
1 - Q_\lambda[E_n] = Q_\lambda \left[ \sum_{k=1}^{n} L_k \leq n\gamma \right] = Q_\lambda \left[ \sum_{k=1}^{n} (L_k - \mathbb{E}_{Q'}[L_k]) \leq -n\delta \right] \\
\leq \frac{\text{var}_{Q_\lambda}(L_1)}{n\delta^2} = \frac{\psi'_Q(\lambda)}{n\delta^2}.
\]

Consequently,

\[
Q \left[ \sum_{k=1}^{n} L_k > n\gamma \right] \geq \exp \left( \frac{-nE_Q(\gamma + \delta) + \log 2}{1 - \frac{\psi'_Q(\lambda)}{n\delta^2}} \right).
\]

\[ \square \]

**Corollary 5.** If Assumption 1 holds and \(-D(Q\|P) \leq \gamma < \gamma + \delta \leq D(P\|Q)\):

\[
\exp (-nE_Q(\gamma)) \geq Q \left[ \sum_{k=1}^{n} L_k > n\gamma \right] \geq \exp \left( \frac{-nE_Q(\gamma + \delta) + \log 2}{1 - \frac{\psi'_Q(\lambda)}{n\delta^2}} \right).
\]

### 4 Weak Recovery for General \( P/Q \) Model

Theorem 1 is proved in Section 4.1. Section 4.2 provides a modification of the sufficiency part of Theorem 1 giving a sufficient condition for weak recovery with random cluster size; it is used in Section 5 to prove sufficient conditions for exact recovery.

#### 4.1 Proof of Theorem 1

**Remark 10.** The sufficiency proof only uses (23) while the necessity proof only uses (24). The sufficiency proof is based on analyzing the MLE via a delicate application of union bound and large deviation upper bounds (3) and (4). For the necessary part, the proof for the first condition in (8) uses a genie argument and the theory of binary hypothesis testing, while the proof of the second condition in (8) is based on mutual information and rate-distortion function.

**Sufficiency** We let \( \hat{C} \) denote the MLE, \( \hat{C}_{\text{ML}} \), for brevity in the proof. Let \( L = |\hat{C} \cap C^*| \) and \( \epsilon = 1/\sqrt{KD(P\|Q)} \). Since \( K \geq 2 \) and \((K-1)D(P\|Q) \rightarrow \infty \) by assumption, we have \( \epsilon = o(1). \) Since \( |\hat{C}| = |C^*| = K \) and hence \( |\hat{C} \triangle C^*| = 2(K - L) \), it suffices to show that \( P\{L \leq (1 - \epsilon)K\} \leq \exp(-\Omega(K/\epsilon)). \)

Note that

\[
e(\hat{C}, \hat{C}) - e(C^*, C^*) = e(\hat{C} \setminus C^*, \hat{C} \cap C^*) + e(\hat{C} \setminus C^*, \hat{C} \cap C^*) - e(C^* \setminus \hat{C}, C^*).
\]

(27)
and $|C^* \setminus \tilde{C}| = |\tilde{C} \setminus C^*| = K - L$. Fix $\theta \in [-D(Q\|P), D(P\|Q)]$ whose value will be chosen later. Then for any $0 \leq \ell \leq K - 1$,

$$\{L = \ell\} \subset \{\exists C \subset [n] : |C| = K, |C \cap C^*| = \ell, e(C, C) \geq e(C^*, C^*)\} = \{\exists S \subset C^*, T \subset (C^*)^c : |S| = |T| = K - \ell, e(S, C^*) \leq e(T, T) + e(T, C^* \setminus S)\} \subset \{\exists S \subset C^*, |S| = K - \ell, e(S, C^*) \leq m\theta\} \cup \{\exists S \subset C^*, T \subset (C^*)^c : |S| = |T| = K - \ell, e(T, T) + e(T, C^* \setminus S) \geq m\theta\},$$

where $m = (\binom{K}{2} - \binom{\ell}{2})$. Notice that $e(S, C^*)$ has the same distribution as $\sum_{i=1}^{m} L_i$ under measure $P$; $e(T, T) + e(T, C^* \setminus S)$ has the same distribution as $\sum_{i=1}^{m} L_i$ under measure $Q$ where $L_i$ are i.i.d. copies of $\log \frac{dP}{dQ}$. Hence, by the union bound and the large deviation bounds (3) and (4),

$$\mathbb{P}\{L = \ell\} \leq \binom{K}{K - \ell} P\left[\sum_{i=1}^{m} L_i \leq m\theta\right] + \binom{n - K}{K - \ell} \left(\frac{K}{K - \ell}\right) Q\left[\sum_{i=1}^{m} L_i \geq m\theta\right] \leq \binom{K}{K - \ell} \exp(-mE_P(\theta)) + \binom{n - K}{K - \ell} \exp(-mE_Q(\theta)) \leq \left(\frac{Ke}{K - \ell}\right)^{K-\ell} \exp(-mE_P(\theta)) + \left(\frac{(n - K)Ke^2}{(K - \ell)^2}\right)^{K-\ell} \exp(-mE_Q(\theta))$$

where the last inequality holds due to the fact that $\binom{n}{\ell} \leq (ea/b)^{\ell}$. Notice that $m = (K - \ell)(K + \ell - 1)/2 \geq (K - \ell)(K - 1)/2$. Thus, for any $\ell \leq (1 - \epsilon)K$,

$$\mathbb{P}\{L = \ell\} \leq e^{-(K-\ell)E_1} + e^{-(K-\ell)E_2}, \tag{28}$$

where

$$E_1 \triangleq (K - 1)E_P(\theta)/2 - \log \frac{e}{\epsilon}, \quad E_2 \triangleq (K - 1)E_Q(\theta)/2 - \log \frac{(n - K)e^2}{Ke^2}.$$ 

By the assumption (7), we have $(K - 1)D(P\|Q)(1 - \eta) \geq 2 \log \frac{1}{\eta}$ for some $\eta \in (0, 1)$. Choose $\theta = (1 - \eta)D(P\|Q)$. By the assumption (23), we have

$$E_1 \geq c\eta^2(K - 1)D(P\|Q)/2 - \log \frac{e}{\epsilon}. \quad (1 - \epsilon)K$$

Using the fact that $E_P(\theta) = E_Q(\theta) - \theta$, we have

$$E_2 \geq c\eta^2(K - 1)D(P\|Q)/2 - 2 \log \frac{e}{\epsilon} + \frac{K - 1}{2} D(P\|Q)(1 - \eta) - \log \frac{n - K}{K} \geq c\eta^2(K - 1)D(P\|Q)/2 - 2 \log \frac{e}{\epsilon}.$$ 

Therefore, in view of $\epsilon = 1/\sqrt{KD(P\|Q)}$, it follows that $E \triangleq \min\{E_1, E_2\} = \Omega(KD(P\|Q)) = \Omega(\epsilon^{-2})$. Hence, in view of (28),

$$\mathbb{P}\{L \leq (1 - \epsilon)K\} = \sum_{\ell=0}^{(1 - \epsilon)K} \mathbb{P}\{L = \ell\} \leq \sum_{\ell=\ell K}^{\infty} \left(e^{-\ell E_1} + e^{-\ell E_2}\right) \leq 2 \exp(-\epsilon KE) \frac{1}{1 - \exp(-E)} = \exp(-\Omega(K/\epsilon)).$$

13
**Necessity**  Given \(i, j \in [n]\), let \(\xi_{i,j}\) denote \(\{\xi_k : k \neq i, j\}\). Consider the following binary hypothesis testing problem for determining \(\xi_i\). If \(\xi_i = 0\), a node \(J\) is randomly and uniformly chosen from \(\{j : \xi_j = 1\}\), and we observe \((A, J, \xi_{i,j})\); if \(\xi_i = 1\), a node \(J\) is randomly and uniformly chosen from \(\{j : \xi_j = 0\}\), and we observe \((A, J, \xi_{i,j})\). Note that

\[
\frac{\mathbb{P}\{J, \xi_{i,j}, A | \xi_i = 0\}}{\mathbb{P}\{J, \xi_{i,j}, A | \xi_i = 1\}} = \frac{\mathbb{P}\{\xi_{i,j}, A | \xi_i = 0, J\}}{\mathbb{P}\{\xi_{i,j}, A | \xi_i = 1, J\}} = \prod_{k \in [n]\setminus \{i, j\}; \xi_k = 1} \frac{Q(A_i k)P(A_{Jk})}{P(A_i k)Q(A_{Jk})},
\]

where the first equality holds because \(\mathbb{P}\{J, \xi = 0\} = \mathbb{P}\{J, \xi = 1\}\); the second equality holds because \(\mathbb{P}\{\xi_{i,j} | \xi_i = 0, J\} = \mathbb{P}\{\xi_{i,j} | \xi_i = 1, J\}\). Let \(T\) denote the vector consisting of \(A_i\) and \(A_J\) for all \(k \in [n]\setminus \{i, j\}\) such that \(\xi_k = 1\). Then \(T\) is a sufficient statistic of \((A, J, \xi_{i,j})\) for testing \(\xi_i = 1\) and \(\xi_i = 0\). Note that if \(\xi_i = 0\), \(T\) is distributed as \(Q_{\otimes(K-1)}P_{\otimes(K-1)}\); if \(\xi_i = 1\), \(T\) is distributed as \(P_{\otimes(K-1)}Q_{\otimes(K-1)}\). Thus, equivalently, we are testing \(Q_{\otimes(K-1)}P_{\otimes(K-1)}\) versus \(P_{\otimes(K-1)}Q_{\otimes(K-1)}\); let \(E\) denote the optimal average probability of testing error. Then we have the following chain of inequalities:

\[
\mathbb{E}[d_H(\xi, \hat{\xi})] \geq \sum_{i=1}^n \min_{\hat{\xi}(A)} \mathbb{P}[\xi_i \neq \hat{\xi}_i] \geq \sum_{i=1}^n \min_{\hat{\xi}(A, J, \xi_{i,j})} \mathbb{P}[\xi_i \neq \hat{\xi}_i] = n \min_{\hat{\xi}(A, J, \xi_{i,j})} \mathbb{P}[\xi_1 \neq \hat{\xi}_1] = nE.
\]

By the assumption \(\mathbb{E}[d_H(\xi, \hat{\xi})] = o(K)\), it follows that \(E = o(K/n)\). Since \(K/n\) is bounded away from one, this implies that the sum of Type-I and II probabilities of error \(p_{e,0} + p_{e,1} = o(1)\), which is equivalent to \(TV((P \otimes Q)_{\otimes(K-1)}, (Q \otimes P)_{\otimes(K-1)}) \rightarrow 1\), where \(TV(P, Q) \triangleq \int |dP - dQ|/2\) denotes the total variation distance. Using \(D(P\|Q) \geq \log \frac{1}{2(1-\text{TV}(P, Q))} \) [38, (2.25)] and the tensorization property of KL divergence for product distributions, we have \((K-1)(D(P\|Q) + D(Q\|P)) \rightarrow \infty\). By the assumption (24) and the fact that \(E_Q(\theta)\) is non-decreasing in \(\theta \in [-D(Q\|P), D(P\|Q)]\), it follows that

\[
D(P\|Q) = E_Q(D(P\|Q)) \geq E_Q(-D(Q\|P)/2) \geq \frac{c}{4} D(Q\|P).
\]

Hence, we have \((K-1)D(P\|Q) \rightarrow \infty\), which implies \(KD(P\|Q) \rightarrow \infty\).

Next we show the second condition in (8) is necessary. Let \(H(X)\) denote the entropy function of a discrete random variable \(X\) and \(I(X; Y)\) denote the mutual information between random variables \(X\) and \(Y\). Let \(\xi = (\xi_1, \ldots, \xi_n)\) be uniformly drawn from the set \(\{x \in \{0, 1\}^n : w(x) = K\}\) where \(w(x) = \sum x_i\) denotes the Hamming weight; therefore \(\xi_i\)’s are individually Bern\((K/n)\). Let \(\mathbb{E}[d_H(\xi, \hat{\xi})] = e_nK\), where \(e_n \rightarrow 0\) by assumption. Consider the following chain of inequalities, which lower bounds the amount of information required for a distortion level \(e_n\):

\[
I(A; \xi) \overset{(a)}{=} I(\hat{\xi}; \xi) \geq \min_{\mathbb{E}[d(H(\xi, \hat{\xi}))] \leq e_nK} I(\hat{\xi}; \xi) \geq H(\xi) - \max_{\mathbb{E}[d(H(\xi, \hat{\xi}))] \leq e_nK} H(\hat{\xi} \oplus \xi)
\]

\[
\overset{(b)}{=} \log \left(\frac{n}{K}\right) - nh \left(\frac{e_nK}{n}\right) \overset{(c)}{\geq} K \log \frac{n}{K}(1 + o(1)),
\]

where (a) follows from the data processing inequality, (b) is due to the fact that \(\max_{\mathbb{E}[w(X)] \leq pn} H(X) = nh(p)\) for any \(p \leq 1/2\) where \(h(p) \triangleq p \log \frac{1}{p} + (1 - p) \log \frac{1}{1-p}\) is the binary entropy function, and

\footnote{To see this, simply note that \(H(X) \leq \sum_{i=1}^n H(X_i) \leq nh(\sum \mathbb{P}(X_i = 1)/n) \leq nh(p)\) by Jensen’s inequality, which is attained with equality when \(X_i\)’s are iid Bernoulli.}
(c) follows from the bound \( \binom{n}{K} \geq \binom{n}{\frac{K}{2}} \), the assumption \( K/n \) is bounded away from one, and the bound \( h(p) \leq -p \log p + p \) for \( p \in [0, 1] \). Moreover,

\[
I(A; \xi) = \min_{\xi} D(\mathbb{P}_{A|\xi} || \mathbb{P}_\xi) \\
\leq D(\mathbb{P}_{A|\xi} || Q^0(\binom{n}{2}) || \mathbb{P}_\xi) \\
= \left( \binom{K}{2} \right) D(P || Q). \tag{30}
\]

Combining the last two displays, we get that \( \liminf_{n \to \infty} \frac{\binom{K-1}{2} D(P || Q)}{\log(n/K)} \geq 2 \).

**Remark 11.** The hidden community model (Definition 1) adopted in this paper assumes the data matrix \( A \) has zero diagonal, meaning that we observe no self information about the individual vertices – only pairwise information. A different assumption used in the literature for the Gaussian submatrix localization problem is that \( A_{ii} \) has distribution \( P \) if \( i \in C^* \) and distribution \( Q \) otherwise. Theorem 1 holds for that case with the modification that the factors \( K-1 \) in (7) and (8) are replaced by \( K+1 \). We explain briefly why the modified theorem is true. The proof for the sufficient part goes through with the definition of \( e(S,T) \) in (1) modified to include diagonal terms indexed by \( S \cap T: e(S,T) = \sum_{(i,j): (i,j) \in (S \times T) \cup (T \times S)} L_{ij} \). Then \( m \) increases by \( K-\ell \), resulting in \( K-1 \) replaced by \( K+1 \) in \( E_1 \) and \( E_2 \). As for the necessary conditions, the proof of the first part of (8) goes through with the sufficient statistic \( T \) extended to include two more variables, \( A_{ii} \) and \( A_{jj} \), which has the effect of increasing \( K \) by one, so the first part of (8) holds with \( K \) replaced by \( K+1 \), but the first part of (8) has the same meaning whether or not \( K \) is replaced by \( K+1 \). The proof of the second part of (8) goes through with \( \binom{K}{2} \) replaced by \( 1 + \cdots + K = \binom{K+1}{2} \) in (30), which has the effect of changing \( K-1 \) to \( K+1 \) in the second part of (8). The necessary conditions and the sufficient conditions for exact recovery stated in the next section hold without modification for the model with diagonal elements. In the proof of Lemma 6, the term \( e(i,C^*) \) in the definition of \( F, \) (40), should include the term \( L_{ii} \) and the random variable \( X_i \) in the proof that \( \mathbb{P} \{ E_1 \} \to 0 \) should be changed to \( X_i = e(i, \{1, \ldots, i\}) \), and also include the term \( L_{ii} \).

### 4.2 A Sufficient Condition For Weak Recovery With Random Cluster Size

Theorem 1 invokes the assumption that \( |C^*| = K \) and \( K \) is known. In the proof of exact recovery, as we will see, we need to deal with the case where \( |C^*| \) is random and unknown. For that reason, the following lemma gives a sufficient condition for weak recovery with a random cluster size. We shall continue to use \( \hat{C}_{ML} \) to denote the estimator defined by (2), although in this context it is not actually the MLE because \( |C^*| \) need not be \( K \). That is, there is a (slight) mismatch between the problem the estimator was designed for and the problem it is applied to.

**Lemma 4** (Sufficient condition for weak recovery with random cluster size). Assume that \( K \to \infty, \limsup K/n < 1, \) and there exists a universal constant \( C > 0 \) such that (23) holds. Furthermore, suppose that

\[
\mathbb{P} \{ |C^*| \leq K/\log K \} \geq 1 - o(1).
\]

If (7) holds, then

\[
\mathbb{P} \{ |\hat{C}_{ML} \Delta C^*| \leq 2K \epsilon + 3K/\log K \} \geq 1 - o(1),
\]

where \( \epsilon = 1/\sqrt{\min \{ \log K, K D(P || Q) \}} \).
Proof. By assumption, with probability converging to 1, \(|C^* - K| \leq K/\log K\). In the following, we assume that \(|C^*| = K'\) for \(|K' - K| \leq K/\log K\). Let \(L = |\hat{C}_{ML} \cap C^*|\). Then \(|\hat{C}_{ML} \Delta C^*| = K + K' - 2L\). To prove the theorem, it suffices to show that \(\mathbb{P}\{L \leq (1 - \epsilon)K - |K' - K|\} = o(1)\), where \(\epsilon\) is defined in the statement of the theorem. Following the proof of Theorem 1 in the fixed cluster size case, we get that for all \(0 \leq \ell \leq K - 1\),

\[
\{L = \ell\} \subset \{\exists C \subset [n] : |C| = K, |C \cap C^*| = \ell, e(C, C) \geq e(C^*, C^*)\}
\]

\[
= \{\exists S \subset C^*: T \subset (C^*)^c : |S| = K' - \ell, |T| = K - \ell, e(S, C^*) \leq e(T, T) + e(T, C^* \setminus S)\}
\]

\[
\subset (S \subset C^*, T \subset (C^*)^c : |S| = K' - \ell, |T| = K - \ell, e(T, T) + e(T, C^* \setminus S) \geq m\theta},
\]

where \(\theta \in [-D(Q\|P), D(P\|Q)]\) is chosen later. Notice that \(e(S, C^*)\) has the same distribution as \(\sum_{i=1}^{m'} L_i\) under measure \(P\); \(e(T, T) + e(T, C^* \setminus S)\) has the same distribution as \(\sum_{i=1}^{m} L_i\) under measure \(Q\) where \(m' = \binom{K}{2} - \binom{K}{2}\), \(m = \binom{K}{2} - \binom{K}{2}\), and \(L_i\) are i.i.d. copies of \(\log \frac{4P}{m}\). Hence, by the union bound and large deviation bounds in (3) and (4),

\[
\mathbb{P}\{L = \ell\} \leq \left(\frac{K'}{K' - \ell}\right)^{P\left[\sum_{i=1}^{m'} L_i \leq m\theta\right] + \binom{n - K'}{K' - \ell}} Q\left[\sum_{i=1}^{m} L_i \geq m\theta\right]
\]

\[
\leq \left(\frac{K'e}{K' - \ell}\right)^{K' - \ell} e^{-m'E_P(m\theta/m')} + \binom{n - K'}{K' - \ell} \left(\frac{K'e}{K' - \ell}\right)^{K' - \ell} e^{-m'E_Q(\theta)}.
\]

Notice that for any \(\ell \leq (1 - \epsilon)K - |K' - K|\), \(K' - \ell \geq \epsilon\max\{K', K\}, K - \ell \geq \epsilon K\), and

\[
\frac{K}{K + K/\log K} \leq \frac{K - \ell}{K' - \ell} \leq \frac{K - \ell}{K - K/\log K} \leq \frac{K - (1 - \epsilon)K}{K - K/\log K - (1 - \epsilon)K}.
\]

Since \(\epsilon \geq 1/\sqrt{\log K}\) and \(K \to \infty\), it follows that \((K - \ell)/(K' - \ell) = 1 + o(1)\). Also,

\[
m' = \binom{K'}{2} - \binom{K'}{2} - 1/2 \geq (K' - \ell)(K' - 1)/2
\]

\[
m = (K - \ell)(K + \ell - 1)/2 \geq (K' - \ell)(K - 1)/2,
\]

Therefore, \(m/m' \to 1\), and, moreover,

\[
\mathbb{P}\{L = \ell\} \leq e^{-(K' - \ell)(1 + o(1))E_1} + e^{-(K - \ell)(1 + o(1))E_2},
\]

with

\[
E_1 = KE_P(m\theta/m')/2 - \log \frac{e}{\epsilon},
\]

\[
E_2 = KE_Q(\theta)/2 - \log \frac{(n - K')e^2}{K^2}.
\]

By the assumption (7), we have \(K\eta D(P\|Q)(1 - \eta) \geq 2\log \frac{\eta}{K}\) for some \(\eta \in (0, 1)\). Choose \(\theta = (1 - \eta)D(P\|Q)\). By (23), we have that \(E_P(\theta) \geq c\eta^2KD(P\|Q)\) and \(E_P(m\theta/m') \geq (1 + o(1))c\eta^2KD(P\|Q)\). Thus,

\[
E_1 \geq (1 + o(1))c\eta^2KD(P\|Q)/2 - \log \frac{e}{\epsilon}.
\]

Using the fact that \(E_P(\theta) = E_Q(\theta) - \theta\), we get that

\[
E_2 \geq c\eta^2KD(P\|Q)/2 - 2\log \frac{e}{\epsilon} + \frac{K}{2}D(P\|Q)(1 - \eta) - \log \frac{n - K'}{K} \geq cK\eta^2D(P\|Q)/2 - 2\log \frac{e}{\epsilon}.
\]

\[16\]
Since $KD(P\|Q) \to \infty$ by assumption $\epsilon \geq 1/\sqrt{KD(P\|Q)}$, it follows that $E = \min\{E_1, E_2\} = \Omega(KD(P\|Q))$. Therefore, \(^5\)

\[
\mathbb{P}\{L \leq (1-\epsilon)K - |K' - K|\} \leq \sum_{\ell=0}^{(1-\epsilon)K} \left( e^{-(K-\ell)(1+o(1))E_1} + e^{-(K-\ell)(1+o(1))E_2} \right) \\
\leq 2 \sum_{\ell=\epsilon K}^{\infty} e^{-(1+o(1))\ell E} = \exp(-\Omega(\sqrt{K^3 D(P\|Q)})) = o(1),
\]

as was to be proved. \(\square\)

5 Exact Recovery for General $P/Q$ Model

The sufficiency and necessity halves of Theorem 2 are proved in Sections 5.1 and 5.2, respectively.

5.1 The Sufficient Condition and the Voting Procedure

This section proves the sufficiency part of Theorem 2. The proof is based on a two-step procedure for exact recovery, described as Algorithm 1. The first main step of the algorithm (approximate recovery) uses an estimator capable of weak recovery, even with a slight mismatch between $|C^*|$ and $K$, such as provided by the ML estimator (see Lemma 4). The second main step cleans up the residual errors through a local voting procedure for each index. In order to make sure the first and second step are independent of each other, we use the method of successive withholding.

This method of proof highlights (13) as the sufficient condition for when the local voting procedure succeeds. In fact, it permits us to prove an intermediate result, Theorem 3 below, which can be used to show that weak recovery plus cleanup in linear additional time can be applied to yield exact recovery no matter how the weak recovery step is achieved. In particular, [22] and [24] give conditions for message passing algorithms to achieve weak recovery in (near linear) polynomial time, and they invoke Theorem 3 to note that, if (13) holds, exact recovery can be achieved with the addition of the linear time cleanup step.

Algorithm 1 Weak recovery plus cleanup for exact recovery

1: (Partition): Partition $[n]$ into $1/\delta$ subsets $S_k$ of size $n\delta$.
2: (Approximate Recovery) For each $k = 1, \ldots, 1/\delta$, let $A_k$ denote the restriction of $A$ to the rows and columns with index in $[n] \setminus S_k$, run an estimator capable of weak recovery with input $(n(1-\delta), [K(1-\delta)], P, Q, A_k)$ and let $\hat{C}_k$ denote the output.
3: (Cleanup) For each $k = 1, \ldots, 1/\delta$ compute $r_i = \sum_{j \in \hat{C}_k} L_{ij}$ for all $i \in S_k$ and return $\tilde{C}$, the set of $K$ indices in $[n]$ with the largest values of $r_i$.

The following theorem gives sufficient conditions under which the two-step procedure achieves exact recovery, assuming the first step provides weak recovery.

Theorem 3. Suppose $\tilde{C}$ is produced by Algorithm 1 using estimators for weak recovery $\hat{C}_k$ such that,

\[
\mathbb{P}\{|\hat{C}_k \Delta C^*_k| \leq \delta K \text{ for } 1 \leq k \leq 1/\delta\} \to 1,
\]

\(\text{(31)}\)

\(^5\)The $o(1)$ terms converge to zero as $K' \to 1$ and $m' \to 1$, uniformly in $\ell$ for $0 \leq \ell \leq (1-\epsilon)K - |K' - K'|$. 

17
as \( n \to \infty \), where \( C^*_k = C^* \cap (\mathbb{N} \setminus S_k) \). Suppose also that Assumption 1 holds (or the weaker conditions (22) and (23) hold), (13) holds. Then \( \mathbb{P}\{ \tilde{C} = C^* \} \to 1 \) as \( n \to \infty \).

The proof of Theorem 3 is given after the following lemma.

**Lemma 5.** Suppose Assumption 1 holds (or the weaker condition (22) holds) and (13) holds. Let \( \{X_i\} \) denote a sequence of i.i.d. copies of \( \log \frac{dP}{dQ} \) under measure \( P \). Let \( \{Y_i\} \) denote another sequence of i.i.d copies of \( \log \frac{dP}{dQ} \) under measure \( Q \), which is independent of \( \{X_i\} \). Then for \( \delta \) sufficiently small and \( \gamma = \frac{1}{K} \log \frac{n}{K^2} \),

\[
\mathbb{P}\left\{ \sum_{i=1}^{K(1-2\delta)} X_i + \sum_{i=1}^{K\delta} Y_i \leq K(1-\delta)\gamma \right\} = o(1/K) \tag{32}
\]

\[
\mathbb{P}\left\{ \sum_{i=1}^{K(1-\delta)} Y_i \geq K(1-\delta)\gamma \right\} = o(1/(n-K)). \tag{33}
\]

**Proof.** By the assumption (13), there exists \( \epsilon > 0 \) sufficiently small such that \( KE_Q(\gamma) \geq (1+\epsilon) \log n \) for all sufficiently large \( n \). We restrict attention to such \( n \). First of all,

\[
\mathbb{P}\left\{ \sum_{i=1}^{K(1-\delta)} Y_i \geq K(1-\delta)\gamma \right\} \leq \exp(-K(1-\delta)E_Q(\gamma)) \leq n^{-(1-\delta)(1+\epsilon)}.
\]

Then (33) holds as long as \( \delta < \frac{1}{1+\epsilon} \). To show (32), for any \( t > 0 \), the Chernoff bound yields

\[
\mathbb{P}\left\{ \sum_{i=1}^{K(1-2\delta)} X_i + \sum_{i=1}^{K\delta} Y_i \leq K(1-\delta)^2 \gamma \right\} \leq \exp(K(1-2\delta)(\psi_P(-t) + \gamma t) + K\delta(\psi_Q(-t) + \gamma t)).
\]

Since \( E_P(\gamma) = \sup_{-1 \leq \lambda \leq 0} \lambda \gamma \geq \psi_P(\lambda), \) choose \( t \in [0, 1] \) so that \( \psi_P(-t) + \gamma t = -E_P(\gamma) = -E_Q(\gamma) + \gamma \).

Since \( \lambda \mapsto \psi_Q(\lambda) \) is convex with \( \psi_Q(0) = 0 \), it follows that

\[
\psi_Q(-t) \leq \psi_Q(-1) \leq D(Q\|P)(1 + C/2),
\]

where the last inequality follows from (22) with \( \lambda = -1 \). Note that (24) is implied by (22). It follows from (24) that \( E_Q(\gamma) \geq E_Q(0) \geq \frac{1}{C} D(Q\|P) \). Together with (34), it yields that \( \psi_Q(-t) \leq C(C + 2)E_Q(\gamma) \). Let \( C' = C(C + 2) \). Combining the above gives

\[
\mathbb{P}\left\{ \sum_{i=1}^{K(1-2\delta)} X_i + \sum_{i=1}^{K\delta} Y_i \leq K(1-\delta)^2 \gamma \right\} \leq \exp(-K(1-2\delta)E_P(\gamma) + K\delta(C' E_Q(\gamma) + K\delta))
\]

\[
= \exp(-K(1-(C'+2)\delta)E_P(\gamma) + K\delta(C' E_Q(\gamma) + K\delta))
\]

\[
\leq \exp\left(-\frac{(C'+2)\delta}{C'}(\log K + \epsilon \log n) + \delta(1 + C') \log n \right),
\]

where the last inequality follows from the assumption that \( KE_P(\gamma) = \log K - \log n + KE_Q(\gamma) \geq \log K + \epsilon \log n \). Therefore, as long as \((1-(C'+2)\delta)(1+\epsilon/2) > 1 \) and \( \delta(1+C') \leq (\epsilon/3)/(1+\epsilon/2) \),

\[
\mathbb{P}\left\{ \sum_{i=1}^{K(1-2\delta)} X_i + \sum_{i=1}^{K\delta} Y_i \leq K(1-\delta)\gamma \right\} \leq \exp\left(-\left(\frac{1}{1+\epsilon/2}\right)(\log K + \frac{2\epsilon}{3} \log n)\right),
\]

so that (32) holds.
Proof of Theorem 3. Note that the conditions of Lemma 5 are satisfied, so that (32) and (33) hold.

Given \((C^*_k, \hat{C}_k)\), each of the random variables \(r_i \in S_k\) for \(i \in [n]\) is conditionally the sum of independent random variables, each with either the distribution of \(X_1\) or the distribution of \(Y_1\) described in Lemma 5. Furthermore, on the event, \(\mathcal{E}_k = \{|\hat{C}_k \Delta C^*_k| \leq \delta K\}\),

\[
|\hat{C}_k \cap C^*_k| \geq |\hat{C}_k| - |\hat{C}_k \Delta C^*_k| = [K(1 - \delta)] - |\hat{C}_k \Delta C^*_k| \geq K(1 - 2\delta),
\]

One can check by definition and the change of measure that the indices of the original graph without replacement. Therefore, by a result of Hoeffding [25], \(\sum_{j=1}^{K(1-\delta)} X_j + \sum_{j=1}^{K\delta} Y_j\). For \(i \in [n] \setminus C^*, r_i\) has the same distribution as \(\sum_{j=1}^{K(1-\delta)} Y_j\). Hence, by (32) and (33) and the union bound, with probability converging to 1, \(r_i > K(1-\delta)\gamma\) for all \(i \in C^*\) and \(r_i < K(1-\delta)\gamma\) for all \(i \in [n] \setminus C^*\). Therefore, \(P(\hat{C} = C^*) \to 1\) as \(n \to \infty\).

Proof of Sufficiency Part of Theorem 2. If \(K\) is bounded, exact recovery is the same as weak recovery, so the sufficiency part of Theorem 2 follows from the sufficiency part of Theorem 1 in that case. So assume for the remainder of the proof that \(K \to \infty\).

In view of Theorem 3 it suffices to verify (31) when \(\hat{C}_k\) for each \(k\) is the MLE for \(C^*_k\) based on observation of \(A_k\), for \(\delta\) sufficiently small. The distribution of \(|C^*_k|\) is obtained by sampling the indices of the original graph without replacement. Therefore, by a result of Hoeffding [25], the distribution of \(|C^*_k|\) is convex order dominated by the distribution that would result by sampling with replacement, namely, by \(\text{Binom}(n(1-\delta), \frac{\delta k}{n})\). That is, for any convex function \(\Psi\), \(E[\Psi(|C^*_k|)] \leq E[\Psi(\text{Binom}(n(1-\delta), \frac{\delta k}{n}))]\). Therefore, Chernoff bounds for \(\text{Binom}(n(1-\delta), \frac{\delta k}{n})\) also hold for \(|C^*_k|\). The Chernoff bounds for \(X \sim \text{Binom}(n, p)\) give:

\[
P\{X \geq (1+\eta)np\} \leq e^{-\eta^2 np/3}, \quad \forall \ 0 \leq \eta \leq 1
\]

(35)

\[
P\{X \leq (1-\eta)np\} \leq e^{-\eta^2 np/2}, \quad \forall \ 0 \leq \eta \leq 1.
\]

(36)

Then,

\[
P\left\{||C^*_k| - (1-\delta)K| \geq \frac{K}{\log K}\right\} \leq P\left\{\left|\text{Binom} \left(n(1-\delta), \frac{K}{n}\right) - (1-\delta)K\right| \geq \frac{K}{\log K}\right\}
\]

\[
\leq e^{-\Omega(K/\log^2 K)} = o(1).
\]

Since (7) holds and \(K \to \infty\), it follows that

\[
\liminf_{n \to \infty} \frac{[(1-\delta)K]D(P\|Q)}{\log \frac{n}{k}} > 2
\]

for any sufficiently small \(\delta \in (0,1)\) with \(1/\delta, n\delta \in \mathbb{N}\). Hence, we can apply Lemma 4 with \(K\) replaced by \(\lceil(1-\delta)K\rceil\) to get that for any \(1 \leq k \leq 1/\delta\),

\[
P\left\{|\hat{C}_k \Delta C^*_k| \leq 2\epsilon K + 3K/\log K\right\} \geq 1 - o(1),
\]

(37)

where \(\epsilon = 1/\sqrt{\min\{\log K, KD(P\|Q)\}}\). Since \(\delta\) is a fixed constant, by the union bound over all \(1 \leq k \leq 1/\delta\), we have that

\[
P\left\{|\hat{C}_k \Delta C^*_k| \leq 2\epsilon K + 3K/\log K\ \text{for} \ 1 \leq k \leq 1/\delta\right\} \geq 1 - o(1).
\]

Since \(\epsilon \to 0\), the desired (31) holds.
5.2 The Necessary Condition

The following lemma gives a necessary condition for exact recovery under the general P/Q model expressed in terms of probabilities for certain large deviations. Later in the section the lemma is combined with the large deviations lower bound of Lemma 3 to establish the necessary conditions in Theorem 2. This method parallels the method used in the previous section for establishing the sufficient condition in Theorem 2.

Lemma 6. Assume that \( K \to \infty \) and \( \limsup K/n < 1 \). Let \( L_i \) denote i.i.d. copies of \( \log \frac{dP}{dQ} \). If there exists an estimator \( \hat{C} \) such that \( P\{\hat{C} = C^*\} \to 1 \), then for any \( K_o \to \infty \) such that \( K_o = o(K) \), there exists a threshold \( \theta_n \) depending on \( n \) such that for all sufficiently large \( n \),

\[
P \left[ \sum_{i=1}^{K-K_o} L_i \leq (K-1)\theta_n - (K_o-1)D(P\|Q) - 6\sigma \right] \leq \frac{2}{K_o},
\]

\[
Q \left[ \sum_{i=1}^{K-1} L_i \geq (K-1)\theta_n \right] \leq \frac{1}{n-K},
\]

where \( \sigma^2 = K_o \text{var}_P(L_1) \) and \( \text{var}_P(L_1) \) denotes the variance of \( L_1 \) under measure \( P \).

Proof. Since the planted cluster \( C^* \) is uniformly distributed, the MLE minimizes the error probability among all estimators. Thus, without loss of generality, we can assume the estimator used \( \hat{C} \) is \( \hat{C}_{ML} \) and the indices are numbered so that \( C^* = [K] \). Hence, by assumption, \( P\{\hat{C}_{ML} = C^*\} \to 1 \).

For each \( i \in C^* \) and \( j \notin C^* \), we have

\[
e(C^* \setminus \{i\} \cup \{j\}, C^* \setminus \{i\} \cup \{j\}) - e(C^*, C^*) = e(j, C^* \setminus \{i\}) - e(i, C^*)
\]

Let \( i_0 \) denote the random index such that \( i_0 = \arg\min_{i \in C^*} e(i, C^*) \). Let \( F \) denote the event that

\[
\min_{i \in C^*} e(i, C^*) \leq \max_{j \in C^*} e(j, C^* \setminus \{i_0\}),
\]

which implies the existence of \( j \notin C^* \), such that the set \( C^* \setminus \{i_0\} \cup \{j\} \) achieves a likelihood at least as large as that achieved by \( C^* \). Since if the event \( F \) happens, then with probability at least 1/2, ML estimator fails, it follows that \( \frac{1}{2} P\{F\} \leq P\{\text{ML fails}\} = o(1) \).

Set \( \theta'_n \) to be

\[
\theta'_n = \inf \left\{ x \in \mathbb{R} : P \left[ \sum_{i=1}^{K-K_o} L_i \leq (K-1)x - (K_o-1)D(P\|Q) - 6\sigma \right] \geq \frac{2}{K_o} \right\},
\]

and \( \theta''_n \) to be

\[
\theta''_n = \sup \left\{ x \in \mathbb{R} : Q \left[ \sum_{i=1}^{K-1} L_i \geq (K-1)x \right] \geq \frac{1}{n-K} \right\}.
\]

Define the events

\[
E_1 = \left\{ \min_{i \in C^*} e(i, C^*) \leq (K-1)\theta'_n \right\}, \quad E_2 = \left\{ \max_{j \notin C^*} e(j, C^* \setminus \{i_0\}) \geq (K-1)\theta''_n \right\}.
\]

We claim that \( P\{E_1\} = \Omega(1) \) and \( P\{E_2\} = \Omega(1) \); the proof is deferred to the end. Note that the random index \( i_0 \) only depends on the the joint distribution of edges with both two endpoints in
Thus $e(j, C^* \setminus \{i_0\})$ for different $j \notin C^*$ are independent and identically distributed, with the same distribution as $\sum_{i=1}^{K-1} L_i$ under measure $Q$. Thus $E_1$ and $E_2$ are independent, so in view of $\mathbb{P}\{F\} = o(1)$,

$$\mathbb{P}\{E_1 \cap E_2 \cap F^c\} \geq \mathbb{P}\{E_1 \cap E_2\} - \mathbb{P}\{F\} = \mathbb{P}\{E_1\} \mathbb{P}\{E_2\} - o(1) = \Omega(1),$$

Since

$$E_1 \cap E_2 \cap F^c \subset \{\theta_n' > \theta_n''\},$$

and $\theta_n', \theta_n''$ are deterministic, it follows that $\theta_n' > \theta_n''$ for sufficiently large $n$. Set $\theta_n = (\theta_n' + \theta_n'')/2$. Thus $\theta_n < \theta_n'$ and by the definition of $\theta_n'$, (38) holds. Similarly, we have that $\theta_n > \theta_n''$ and by the definition of $\theta_n''$, (39) holds.

We are left to show $\mathbb{P}\{E_1\} = \Omega(1)$ and $\mathbb{P}\{E_2\} = \Omega(1)$. We first prove that $\mathbb{P}\{E_2\} = \Omega(1)$. Since $Q\left[\sum_{i=1}^{K-1} L_i \geq x\right]$ is left-continuous in $x$, it follows that $Q\left[\sum_{i=1}^{K-1} L_i \geq (K-1)\theta_n'' \geq (n-K)^{-1}\right]$. Therefore,

$$\mathbb{P}\{E_2\} = 1 - \prod_{j \notin C^*} \mathbb{P}\{e(j, C^*) < (K-1)\theta_n''\}$$

$$= 1 - \left(1 - Q\left[\sum_{i=1}^{K-1} L_i \geq (K-1)\theta_n''\right]\right)^{n-K}$$

$$\geq 1 - \exp\left(-Q\left[\sum_{i=1}^{K-1} L_i \geq (K-1)\theta_n''\right](n-K)\right) \geq 1 - e^{-1},$$

where the first equality holds because $e(j, C^* \setminus \{i_0\})$ is independent for different $j \notin C^*$; the second equality holds because $e(j, C^* \setminus \{i_0\})$ has the same distribution as $\sum_{i=1}^{K-1} L_i$ under measure $Q$; the third inequality is due to $1 - x \leq e^{-x}$ for $x \in \mathbb{R}$; the last inequality holds because $Q\left[\sum_{i=1}^{K-1} L_i \geq (K-1)\theta_n'' \geq (n-K)^{-1}\right]$. So $\mathbb{P}\{E_2\} = \Omega(1)$ is proved.

Next, we show that $\mathbb{P}\{E_1\} = \Omega(1)$. The proof is similar to the proof of $\mathbb{P}\{E_2\} = \Omega(1)$ just given, but it is complicated by the fact the random variables $e(i, C^*)$ for $i \in C^*$ are not independent. Since $P\left[\sum_{i=1}^{K-K_o} L_i \leq x\right]$ is right-continuous in $x$, it follows from the definition that

$$P\left[\sum_{i=1}^{K-K_o} L_i \leq (K-1)\theta_n' - (K_o-1)D(P\|Q) - 6\sigma\right] \geq \frac{2}{K_o}. \quad (41)$$

For all $i \in C^*$, $e(i, C^*)$ has the same distribution as $\sum_{i=1}^{K-1} L_i$ under measure $P$, but they are not independent. Let $T$ be the set of the first $K_o$ indices in $C^*$, i.e., $T = [K_o]$, where $K_o = o(K)$ and $K_o \to \infty$. Let $\sigma^2 = K_o \text{var}_P(L_1)$, where $\text{var}_P(L_1)$ denotes the variance of $L_1$ under measure $P$, and let $T' = \{i \in T : e(i, T) \leq (K_o-1)D(P\|Q) + 6\sigma\}$. Since

$$\min_{i \in C^*} e(i, C^*) \leq \min_{i \in T'} e(i, C^*) \leq \min_{i \in T'} e(i, C^* \setminus T) + (K_o - 1)D(P\|Q) + 6\sigma,$$

it follows that

$$\mathbb{P}\{E_1\} \geq \mathbb{P}\left\{\min_{j \in T'} e(j, C^* \setminus T) \leq (K-1)\theta_n' - (K_o-1)D(P\|Q) - 6\sigma\right\}.$$
We show next that $\mathbb{P}\left\{|T'| \geq \frac{K_o}{2}\right\} \rightarrow 1$ as $n \rightarrow \infty$. For $i \in T$, $e(i,T) = X_i + Y_i$ where $X_i = e(i,\{1, \ldots, i-1\})$ and $Y_i = e(i,\{i+1, \ldots, K_o\})$. The $X$’s are mutually independent, and the $Y$’s are also mutually independent, and $X_i$ has the same distribution as $\sum_{j=1}^{K_o-1} L_j$, where $L_j$ is distributed under measure $P$. Then $\mathbb{E}[X_i] = (i-1)D(P||Q)$ and $\text{var}(X_i) \leq \frac{\sigma^2}{2}$. Thus, by the Chebyshev inequality, $\mathbb{P}\left\{X_i \geq (i-1)D(P||Q) + 3\sigma\right\} \leq \frac{1}{9}$ for all $i \in T$. Therefore, $\{i : X_i \leq (i-1)D(P||Q) + 3\sigma\}$ is stochastically at least as large as a Binom($K_o, \frac{8}{9}$) random variable, so that, $\mathbb{P}\left\{\{i : X_i \leq (i-1)D(P||Q) + 3\sigma\} \geq \frac{3K_o}{4}\right\} \rightarrow 1$ as $K_o \rightarrow \infty$. Similarly, $\mathbb{P}\left\{\{i : Y_i \leq (K_o - i)D(P||Q) + 3\sigma\} \geq \frac{3K_o}{4}\right\} \rightarrow 1$ as $K_o \rightarrow \infty$. If at least 3/4 of the $X$’s are small and at least 3/4 of the $Y$’s are small, it follows that at least 1/2 of the $e(i,T)$’s for $i \in T$ are small. Therefore, as claimed, $\mathbb{P}\left\{|T'| \geq \frac{K_o}{2}\right\} \rightarrow 1$ as $K_o \rightarrow \infty$.

The set $T'$ is independent of $(e(i, C^* \setminus T) : i \in T)$ and each of those variables has the same distribution as $\sum_{j=1}^{K-K_o} L_j$ under measure $P$. Thus,

$$
\mathbb{P}\{E_1\} \\
\geq 1 - \mathbb{E}\left[\prod_{j \in T'} \mathbb{P}\{e(j, C^* \setminus T) \geq (K-1)\theta_n' - (K_o - 1)D(P||Q) - 6\sigma\mid |T'| \geq \frac{K_o}{2}\} - \mathbb{P}\{|T'| < \frac{K_o}{2}\}\right] \\
\geq 1 - \exp\left(-\mathbb{P}\left[\sum_{j=1}^{K-K_o} L_j \leq (K-1)\theta_n' - (K_o - 1)D(P||Q) - 6\sigma\mid K_o/2\right] - o(1)\right) \\
\geq 1 - e^{-1} - o(1),
$$

where the last inequality follows from (41). Therefore, $\mathbb{P}\{E_1\} = \Omega(1)$.

**Proof of Necessary Part of Theorem 2.** Since the joint condition (8) is necessary for weak recovery, and hence also for exact recovery, it suffices to prove (14) under the assumption that (8) holds, i.e.,

$$KD(P||Q) \rightarrow \infty, \quad KD(P||Q) \geq (2 - \epsilon_0) \log(n/K) \quad (42)$$

for any fixed constant $\epsilon_0 \in (0,1)$ and all sufficiently large $n$. It follows that

$$E_Q\left(\frac{1}{K} \log \frac{n}{K}\right) \leq E_Q(D(P||Q)) = D(P||Q).$$

Thus if $K = O(1)$, then (42) implies (14). Hence, we assume $K \rightarrow \infty$ in the following without loss of generality.

For the sake of argument by contradiction, suppose that (14) does not hold. Then, by going to a subsequence, we can assume that

$$\limsup_{n \rightarrow \infty} \frac{KE_Q(\gamma)}{\log n} < 1, \quad (43)$$

where $\gamma = \frac{1}{K} \log \frac{n}{K}$. It follows from (42) that $\gamma \leq \frac{1}{2-\epsilon_0} D(P||Q)$.

We shall apply Lemma 6 to argue a contradiction. As a witness to the nonexistence of $\theta_n$ satisfying (38) and (39) we show that if $\theta_n = \gamma$ then neither (38) nor (39) holds. By Lemma 2, $D(P||Q) \asymp D(Q||P)$. Since $0 \leq \gamma \leq \frac{1}{2-\epsilon_0} D(P||Q)$, choosing $\delta > 0$ to be a sufficiently small constant ensures that both $\gamma$ and $\gamma + \delta D(Q||P)$ lie in $[-D(Q||P), D(P||Q)]$. Then Assumption 1 and Corollary 5 yield:

$$Q\left[\sum_{i=1}^{K-1} L_i \geq (K-1)\gamma\right] \geq \exp\left(-\frac{(K-1)E_Q(\gamma + \delta D(Q||P)) + \log 2}{1 - \frac{C}{(K-1)\delta^2 D(P||Q)}}\right).$$

22
By the properties of $E_Q$ discussed in Remark 3,

$$E_Q (\gamma + \delta D(Q\|P)) \leq E_Q(\gamma) + \delta D(Q\|P),$$

and by Lemma 2,

$$\delta D(Q\|P) \leq 2\delta CE_Q(0) \leq 2\delta CE_Q(\gamma),$$

so, in view of (43), if $\delta$ is sufficiently small,

$$(K - 1)E_Q(\gamma + \delta D(Q\|P)) < (1 - 2\delta) \log n$$

for all sufficiently large $n$. Also, recall that $D(P\|Q) \asymp D(Q\|P)$ and hence (42) implies that $KD(Q\|P) \to \infty$. Therefore,

$$Q \left[ \sum_{i=1}^{K-1} L_i \geq (K - 1)\gamma \right] \geq n^{-1+\delta}$$

for all sufficiently large $n$. Thus, (39) does not hold for $\theta_n \equiv \gamma$.

Turning to (38) (with $\theta_n = \gamma$), we let $K_o = K/\log K$ and

$$\delta' \triangleq (K_o - 1)(D(P\|Q) - \gamma) + 6\sigma$$

where $\sigma = \text{var}_P[L]$. Note that $\text{var}_P[L] = \psi'_Q(1) \geq CD(P\|Q)$ by Assumption 1 and recall that from (42) we have $\gamma \leq \frac{1}{2 - \epsilon_0}D(P\|Q)$. Furthermore, since $K \to \infty$ and $KD(P\|Q) \to \infty$ by (42), we conclude that $\delta' = o(1)$.

Since $D(P\|Q) \asymp D(Q\|P)$ and $0 \leq \gamma \leq \frac{1}{2 - \epsilon_0}D(P\|Q)$, choosing $\delta$ to be a sufficiently small constant ensures that both $\gamma - \delta' D(P\|Q)$ and $\gamma - (\delta' + \delta)D(P\|Q)$ lie in $[-D(Q\|P), D(P\|Q)]$. Hence, applying Corollary 5 yields

$$P \left[ \sum_{i=1}^{K-K_o} L_i \leq (K - 1)\gamma - (K_o - 1)D(P\|Q) - 6\sigma \right]
\quad = P \left[ \sum_{i=1}^{K-K_o} L_i \leq (K - K_o) (\gamma - \delta' D(P\|Q)) \right] \geq \exp \left( - \frac{(K - K_o)E_P(\gamma - (\delta' + \delta)D(P\|Q)) + \log 2}{1 - \frac{C}{(K-K_o)\delta^2D(P\|Q)}} \right).$$

Moreover, in view of the fact that $E_P(\cdot)$ is decreasing and (23),

$$E_P(\gamma) \geq E_P(D(P\|Q)/(2 - \epsilon_0)) \geq \frac{(1 - \epsilon_0)^2 D(P\|Q)}{2(2 - \epsilon_0)^2C}$$

Let $C' = \frac{(1 - \epsilon_0)^2}{2(2 - \epsilon_0)^2C}$. Therefore, similar to the properties of $E_Q$ discussed in Remark 3,

$$E_P(\gamma - (\delta' + \delta)D(P\|Q)) \leq E_P(\gamma) + (\delta' + \delta)D(P\|Q) \leq E_P(\gamma (1 + (\delta' + \delta)/C')).$$
Since $E_P(\gamma) = E_Q(\gamma) - \gamma$, by (43), there exist some $\epsilon > 0$ such that

$$KE_P(\gamma) \leq (1 - \epsilon) \log n - \log(n/K) = -\epsilon \log n + \log K \leq (1 - \epsilon) \log K.$$  

Thus by choosing $\delta$ sufficiently small and in view of $\delta' = o(1)$,

$$(K - K_o)E_P(\gamma - (\delta' + \delta)D(P\|Q)) \leq (1 - 2\epsilon') \log K$$  

for some $\epsilon' > 0$. Recall that $KD(P\|Q) \to \infty$, it readily follows from (45) that

$$P \left[ \sum_{i=1}^{K-K_o} L_i \leq (K-1)\gamma - (K_o-1)D(P\|Q) - 6\sigma \right] \geq K^{-1+\epsilon'}.$$  

Thus, with $\theta_n = \gamma$, neither (38) nor (39) holds for all sufficiently large $n$. Therefore, there does not exist a sequence $\theta_n$ such that both (38) and (39) hold for all sufficiently large $n$, contradicting the conclusion of Lemma 6. □

**Appendices**

**A  Equivalence of Weak Recovery in Expectation and in Probability**

**Lemma 7.** There exists an estimator $\hat{\xi}$ such that $\frac{d_H(\xi, \hat{\xi})}{K} \to 0$ in probability if and only if there exists an estimator $\hat{\xi}$ such that $\mathbb{E}\left[\frac{d_H(\xi, \hat{\xi})}{K}\right] \to 0$.

**Proof.** One direction is automatic because convergence in $L_1$ implies convergence in probability. Conversely, suppose $\frac{d_H(\xi, \hat{\xi})}{K} \to 0$ in probability for some (sequence of) $\hat{\xi}$. Then there exists a deterministic sequence $\epsilon_n \to 0$ such that $P\{d_H(\xi, \hat{\xi}) \geq \epsilon_nK\} \leq \epsilon_n$. Define a new estimator by

$$\tilde{\xi} = \hat{\xi}1_{\{||\tilde{\xi}\| \leq K+\epsilon_nK\}} + 0 \cdot 1_{\{||\tilde{\xi}\| > K+\epsilon_nK\}},$$  

where 0 denotes the all-zero vector. Since $||\xi|| = K$, by the triangle inequality, we have

$$\mathbb{E}[d_H(\xi, \tilde{\xi})] = \mathbb{E}\left[d_H(\xi, \hat{\xi})1_{\{||\hat{\xi}\| \leq K+\epsilon_nK\}}\right] + K\mathbb{P}\{||\hat{\xi}\| > K+\epsilon_nK\} \leq \epsilon_nK + \mathbb{E}\left[d_H(\xi, \hat{\xi})1_{\{d_H(\xi, \hat{\xi}) > \epsilon_nK, ||\hat{\xi}\| \leq K+\epsilon_nK\}}\right] + K\mathbb{P}\{||\hat{\xi}\| > K+\epsilon_nK\} \leq \epsilon_nK + (3K + \epsilon_nK)\mathbb{P}\{d_H(\xi, \hat{\xi}) > \epsilon_nK\} \leq 4\epsilon_nK + \epsilon_n^2K.$$  

Therefore, $\frac{d_H(\xi, \hat{\xi})}{K} \to 0$. □

**B  Assumption 1 for exponential families of distributions**

There is a simple sufficient condition for Assumption 1 to hold in case $P$ and $Q$ are from the same exponential family of distributions (including Bernoulli, Gaussian, etc). Consider a canonical
exponential family with the following pdf (with respect to some dominating measure):\(^8\)

\[ p_\theta(x) = h(x) \exp(\theta T(x) - A(\theta)), \]

where \( A \) is a convex function. Then \( E_\theta[T] = A'(\theta) \) and \( \text{var}_\theta[T] = A''(\theta). \) Assume that \( P \) and \( Q \) correspond to parameters \( \theta_1 \) and \( \theta_0 \), respectively. It could be that \( \theta_0 < \theta_1 \) or \( \theta_1 < \theta_0; \) let \( I \) denote the interval with endpoints \( \theta_0 \) and \( \theta_1 \) and \( J \) denote the interval with endpoints \( \theta_0 \pm (\theta_1 - \theta_0) \). Then \( Q_\lambda \) has parameter \( \lambda \theta_1 + \lambda \theta_0 \). Furthermore,

\[
L = (\theta_1 - \theta_0) T - A(\theta_1) + A(\theta_0)
\]

\[
D(P \| Q) = A(\theta_1) - A(\theta_0) - (\theta_1 - \theta_0) A'(\theta_0)
\]

\[
C(P, Q) = - \min_{\theta \in I} A(\theta)
\]

\[
\psi_Q(\lambda) = A(\lambda \theta_1 + \lambda \theta_0) - \lambda A(\theta_0) - \lambda A(\theta_1)
\]

\[
\psi_Q''(\lambda) = A''(\lambda \theta_1 + \lambda \theta_0) (\theta_1 - \theta_0)^2.
\]

By Taylor’s theorem, \( D(P \| Q) \) is \( \frac{(\theta_0 - \theta_1)^2}{2} \) times a weighted average of \( A'' \) over \( I \):

\[
D(P \| Q) = \frac{(\theta_1 - \theta_0)^2}{2} \int_{\theta_0}^{\theta_1} A''(s) (s - \theta_0) ds / (\theta_1 - \theta_0)^2 / 2
\]

Similarly, \( D(Q \| P) \) is a weighted average of \( A'' \) over \( I \). Therefore, a sufficient condition for Assumption 1 is

\[
\frac{\max_{\theta \in I} A''(\theta)}{\min_{\theta \in I} A''(\theta)} = O(1).
\]

(47)

Examples:

1. Gaussian: \( \theta = \mu \), \( A(\theta) = \theta^2 / 2 \) and \( A''(\theta) = 1 \). So \( (47) \) holds in the Gaussian case with no extra assumption.

2. Bernoulli: \( \theta = \log \frac{q}{p} \), \( A(\theta) = \log(1 + e^\theta) \) and \( A''(\theta) = \frac{e^\theta}{(1 + e^\theta)^2} = p(1 - p). \) We shall show that if \( p, q \) vary such that \( p, q \in (0, 1) \) with \( p \neq q \), then \( (47) \) is equivalent to boundedness of the LLR. By symmetry between 0 and 1 we can assume without loss of generality that \( 0 < q < p < 1 \). First, if \( p \leq 1/2 \) the LHS of \( (47) \) is \( \frac{\theta_p}{q} \times \frac{p}{q} \) and if \( p \in [1/2, 1 - \epsilon] \) for some fixed \( \epsilon > 0 \) then the LHS of \( (47) \) has size \( \Theta(1/q) = \Theta(p/q) \). So the claim is true if \( p \) is bounded away from one.

If \( p \to 1 \) and \( q \not \to 1 \) then both the LHS of \( (47) \) and the LLR are unbounded, so the claim is again true.

It remains to check the case \( p, q \to 1 \). The denominator of the LHS of \( (47) \) is \( \frac{p p}{q} \times \hat{p} \). The maximum in the numerator is taken over the interval \([\theta_{-1}, \theta_{1}]\), where \( \theta_{-1} = \theta_0 - [\theta_1 - \theta_0] = \log \left( \frac{2 \theta_{-1}}{\theta_1 - \theta_{-1}} \right) \). If \( \theta_{-1} \leq 0 \) (i.e. \( \theta_0 \leq \theta_1 / 2 \)) then the numerator of the LHS of \( (47) \) is 1/4, so \( (47) \) fails to hold, and also, \( \frac{\theta_{-1}}{\theta_1} = O(\sqrt{p}) \) so the LLR is unbounded. It thus remains to consider the case \( \theta_{1}/2 \leq \theta_0 \leq \theta_1 \) with \( \theta_1 \to \infty \). The numerator of the LHS of \( (47) \) is \( r \hat{r} \) where \( r \) is determined by \( \theta_{-1} = \log \frac{r}{\hat{r}} \) or, equivalently, \( \frac{r}{\hat{r}} = \frac{\theta_{-1}^2}{\theta_1^2} \). Hence \( \hat{r} \times \frac{q}{p} \). The LHS of \( (47) \) is \( \frac{r}{pp} \times \hat{r} \times \left( \frac{\theta}{p} \right)^2 \) while the maximum absolute value of the LLR is \( \Theta(\log \hat{r} / p) \). Hence, again, \( (47) \) holds if and only if the LLR is bounded. The claim is proved.

\(^8\)For simplicity we assume \( T \) and \( \theta \) are scalar valued. Vector values would give \( p_\theta(x) = h(x) \exp(\langle \theta, T(x) \rangle - A(\theta)) \) and the condition \( (47) \), with \( A''(\theta) \) replaced by \( \langle \theta_1 - \theta_0 \rangle H(\theta)(\theta_1 - \theta_0) \), where \( H \) is the Hessian of \( A \), and \( I \) and \( J \) becoming line segments, is still sufficient for Assumption 1.
C Proof of Corollary 4

In the Gaussian case, $E_Q(\theta) = \frac{1}{8} (\mu + \frac{2\theta}{\mu})^2$. Throughout this proof, let $\theta = \frac{1}{4} \log \frac{n}{K}$ and let $f$ be the function defined by $f(\mu) = E_Q(\theta) = \frac{1}{8} (\mu + \frac{2\theta}{\mu})^2$. Consider the equation $f(\mu) = \frac{\log n}{K}$. It yields a quadratic equation in $\mu^2$: $\mu^4 - \frac{4 \log n}{K} + \frac{4 \log^2 (n/K)}{K^2} = 0$ which has two solutions namely $\mu^2_{\pm} = \frac{2}{K} (\sqrt{\log n} \pm \sqrt{\log K})^2$. Without loss of generality, we take $\mu_+ > 0$ and $\mu_- > 0$; the case of $\mu_+ < 0$ and $\mu_- < 0$ follows analogously. In summary, the expressions inside the lim inf in both (13) and (19) are one if $\mu$ is replaced by $\mu_+$.

For the sufficiency part, suppose $\mu$ depends on $n$ such that (11) and (19) hold. By (19), for $\epsilon > 0$ sufficiently small, $\mu(1 - \epsilon) \geq \mu_+$ for all sufficiently large $n$. We can also take $\epsilon < 1/10$. By (11), $\limsup \frac{\theta}{\mu^2} \leq \frac{1}{4}$ so uniformly for $(1 - \epsilon) \mu \leq x \leq \mu$,

\[
\begin{align*}
f'(x) &= \frac{1}{4} \left( x + \frac{2\theta}{x} \right) \left( 1 - \frac{2\theta}{x^2} \right) \\
&\geq \frac{1}{4} ((1 - \epsilon) \mu) \left( 1 - \frac{2\theta}{(1 - \epsilon)^2 \mu^2} \right) = \Omega(\mu).
\end{align*}
\]

Also, $\frac{2\theta}{\mu^2} < 1$ so $f'(x) \geq 0$ for $x \geq \mu_+$. Hence,

\[
\frac{f(\mu)}{f(\mu_+)} - 1 \geq \frac{f(\mu) - f(\mu(1 - \epsilon))}{f(\mu_+)} = \frac{K}{\log n} \int_{\mu(1 - \epsilon)}^{\mu} f'(x) dx = \Omega \left( \frac{\epsilon K \mu^2}{\log n} \right) = \Omega(\epsilon),
\]

where for the last equality we use $\mu^2 \geq \mu^2_{\pm} \geq \frac{2 \log n}{K}$. Therefore (13) holds, sufficiency follows from Theorem 2.

For the necessity part, it suffices to show that (12) and (14) imply (20). If $K \leq n^{1/9}$ then (12) alone implies (20), so we can also assume that $K \geq n^{1/9}$. It follows that $\frac{2\theta}{\mu^2_+} = \frac{\sqrt{\log n} \sqrt{\log K}}{\sqrt{n^{1/9} \log K}} \leq \frac{1}{2}$. Therefore, for $\epsilon \in (0, 0.1)$,

\[
\begin{align*}
f(\mu_+(1 - \epsilon)) &\leq f(\mu_+) - \epsilon \mu_+ \min \{ f'(x) : (1 - \epsilon) \mu_+ \leq x \leq \mu_+ \} \\
&\leq f(\mu_+) - \epsilon \mu_+ \min \{ f'(x) : (1 - \epsilon) \mu_+ \leq x \leq \mu_+ \} \\
&\leq f(\mu_+) - \frac{\epsilon \mu_+}{4} (1 - \epsilon) \mu_+ \left( 1 - \frac{1}{2(1 - \epsilon)^2} \right) \\
&\leq f(\mu_+) - \Omega(\epsilon \mu^2_+) \leq \frac{\log n}{K} (1 - \Omega(\epsilon)).
\end{align*}
\]

In view of (14) it follows that $\mu \geq \mu_+(1 - \epsilon)$ for all sufficiently large $n$. Since $\epsilon$ can be arbitrarily small, (20) follows.
