Abstract

**Background:** The global burden of cardiovascular disease (CVD) is forecast to increase, and anticoagulants will remain important medicines for its management. Coroners' Prevention of Future Death reports (PFDs) provide valuable insights that may enable safer and more effective use of these agents.

**Objective:** To identify CVD-related PFD reports highlighting the use or lack of anticoagulants as having caused or contributed to deaths.

**Methods:** We conducted a retrospective observational study of coronial case reports in England and Wales between 2013 and 2019. We screened 3037 PFDs for inclusion and used content analysis to assess concerns raised by coroners and who responded to them.

**Results:** We identified 113 CVD-related PFDs (113 deaths) involving anticoagulants. Warfarin (36%), enoxaparin (11%), and rivaroxaban (11%) were the most common anticoagulants reported. In 14 cases, the coroner mentioned that the administration of an anticoagulant may have prevented the death. Concerns most frequently raised by coroners included poor systems (31%), poor communication (25%), and failures to keep accurate medical records (25%). These concerns were most often directed to NHS trusts (29%), hospitals (10%), and general practices (8%), but had national importance. Nearly two-thirds (60%) of PFDs had not received responses from such organisations, which are mandatory under regulation 28 of the Coroners' (Investigations) Regulations 2013.

**Conclusions:** We created a tool ([https://preventabledoathstracker.net/](https://preventabledoathstracker.net/)) that bring together coroner reports to identify important lessons related to preventable deaths. Here we examined instances of premature deaths from CVD involving anticoagulants. National organisations, healthcare professionals, and prescribers should take actions to address these concerns, to improve the use of anticoagulants in patients with CVD.

**Keywords:** cardiovascular diseases, anticoagulants, inappropriate prescribing, medication errors, premature mortality, coroners and medical examiners
Key questions

What is already known?
A previous assessment of 500 PFDs identified anticoagulants as the class of drugs most often involved in fatal medication errors.

What does this study add?
We used innovative methods to automatically collect all available PFDs, in order to identify deaths from cardiovascular disease when the use of or lack of anticoagulants caused or contributed to the death. We found that communication, following protocols, education and training, access to resources, and safety issues were raised as concerns by coroners. Despite having national relevance, most CVD-anticoagulant PFDs were sent locally to NHS Trusts, hospitals, and general practices.

How might this impact on clinical practice?
Local dissemination and poor responses to PFDs limits the ability of lessons to be learnt and actions to be implemented to reduce harms and prevent premature deaths from cardiovascular disease involving anticoagulants. The concerns highlighted by coroners should be addressed by national organisations to improve safety and management of patients with cardiovascular disease.
Introduction

Cardiovascular disease (CVD) is the leading cause of mortality worldwide [1,2]. In 2019, 18.6 million deaths (33% of all deaths) were due to CVD [3], with a projection of 24 million annual deaths by 2030 [4]. In England and Wales, CVD was responsible for almost a quarter of all deaths in 2019 [5,6]. Premature mortality from CVD in England has also been attributed to greater socioeconomic inequalities in people under 75 years of age [7].

In patients at high risk of strokes, heart attacks, deep vein thrombosis, or pulmonary embolism, anticoagulation is one possible prophylactic intervention [8]. Anticoagulants target different points of the coagulation cascade, helping to prevent blood clot formation and the adverse effects of excessive clotting. Three main types of anticoagulants are outlined in NICE guidelines: low molecular weight heparin (e.g. enoxaparin), vitamin K antagonists (e.g. warfarin), and direct-acting oral anticoagulants (DOACs; e.g. rivaroxaban). The effectiveness of anticoagulants for cardiovascular disease is well established. For example, adjusted-dose warfarin reduced stroke by 62% (95% CI: 48% to 72%) in patients with atrial fibrillation [9]. However, the narrow therapeutic index and frequent laboratory monitoring needed with warfarin administration have led to the development of DOACs [10]. Bleeding associated with warfarin therapy is among the top three adverse drug reactions that cause hospital admissions in England [11].

In English primary care, prescribing of anticoagulants increased from 15 million doses to 33 million between January 2014 and August 2019 [12]. Coroners’ reports, previously named Rule 43 reports and now called Prevention of Future Death reports (PFDs), are mandated under paragraph 7 of Schedule 5 of the Coroners and Justice Act 2009, when the coroner believes that action is necessary to prevent a death [13]. PFDs are sent to specific individuals or organisations, who, under regulation 28 and 29 of the Coroners (Investigations) Regulations 2013, have a duty to respond within 56 days of the date of report [14]. Previous analysis of coroners’ reports has shown that anticoagulants were the drugs most commonly reported to have been involved in fatal medication errors in England and Wales [15]. But that research examined only a proportion (n=500) of all published coroners’ reports. Building on previous research, we aimed to assess all available PFDs on deaths in individuals with CVD, in whom the use or lack of use of anticoagulants caused or contributed to the death. We sought to discover: 1) what concerns were highlighted by coroners; 2) to which individuals or
organizations PFDs were addressed; 3) whether responses were made by the individuals or organizations to whom the PFDs were sent.

Methods
We designed a retrospective observational study and preregistered our study protocol on an open repository [16]. We used the STROBE reporting guideline to write our manuscript.

Data collection
PFDs are openly available on the Courts and Tribunals Judiciary website [17]. We used web scraping to automatically collect PFDs, and from the output created the Preventable Deaths Database and the Preventable Deaths Tracker: https://preventabledethstracker.net/ [18]. The code to create the scraper is openly available on GitHub [19] and has been previously described [20]. The Preventable Deaths Database contains: the case reference number; the date of the report; the name of the deceased; the coroner's name; the coroner’s jurisdiction; the category of death (defined by the Chief Coroners’ office); to whom the report was sent; and the URL to the Judiciary website. For population data on deaths from CVD, we used the most recent (2001-2019) dataset of deaths registered in England and Wales, released by the Office for National Statistics in 2020 (ONS) [5].

Eligibility of cases
We examined all cases (n=3037) in the Preventable Deaths Database from July 2013 (the first date on which they were uploaded to the Judiciary website) to December 2019. We screened the cases independently in duplicate (AA & GCR) to determine whether CVD caused or contributed to the death using a pre-defined algorithm (Supplementary Figure 1). We used Chapter IX (Diseases of the Circulatory System) of the International Statistical Classification of Diseases and Related Health Problems 10th Revision (ICD-10) to align with the ONS classifications of death. When the deceased suffered from a single condition listed under chapter IX that could not be unequivocally attributed to external causes, the case was included. We then screened cases for whether an anticoagulant(s) caused or contributed to the death or where the coroner suggested that had an anticoagulant been given, it would have prevented the death. We defined anticoagulants as agents targeting different points of the coagulation pathway to prevent clot formation. Discrepancies were resolved by consensus discussion (AA, GCR, & JKA).
Data extraction

For included cases, one study author (AA) manually extracted the following variables into a predesigned Google Sheet: the individuals or organizations to whom reports were sent, who responded, the due date of response and the date received; date of death; the dates on which the inquest started and ended; age; sex; setting or location of death; medical cause(s) of death; the coroner's conclusion(s) of the inquest; relevant medical, mental health, and social history; whether any substance(s) were implicated in the death and the type of substance(s); coroner's concern(s) and actions proposed by the coroner.

Data analysis

To determine the annual deaths from CVD in England and Wales, we filtered the ONS data [5] for deaths caused by conditions listed under chapter IX of ICD-10 (ICD-10 codes: I00-I99). We summed the number of reports written each year and compared the totals with ONS mortality data for CVD. We used descriptive statistics to report the quantitative findings and performed content analysis [21] to classify the concerns and actions raised by coroners with categories derived inductively. We calculated a response rate for each organisation as the proportion of reports to which a response was submitted over the total number received. Responses were further classified as either on-time (delivered within 56 days), late (submitted after 56 days), or overdue (when no response was found on the Judiciary website). A response rate of 100% means that individual or organisation adhered to regulation 28 of the Coroners' (Investigations) Regulations 2013 and responded to all PFDs issued by coroners. We used Python v3.7 in Jupyter Notebooks with pandas, seaborn, and matplotlib libraries to analyse the data and create figures. The data, statistical code, and study materials are openly available via the Open Science Frame [22] and GitHub [23].

Results

In 659 cases (22% of all PFDs) CVD caused or contributed to the death (Figure 1). Of the CVD-related PFDs, 17% (n=113) involved or mentioned the use or lack of an anticoagulant. Over the seven-year study period, there was a median of 16 (IQR: 15-17) CVD-related anticoagulant PFDs each year (Supplementary Table 1).
In 99 cases, an anticoagulant(s) caused or contributed to the death. Warfarin (36%) was the most common anticoagulant specified, followed by enoxaparin (11%) and rivaroxaban (11%) (Figure 2). In 14 cases, the coroner mentioned that the administration of an anticoagulant might have prevented the death (Figure 2). There were equal proportions of males (n=56) and females (n=57) in the 113 cases. The median age of the deceased were 76 years (IQR: 61-84 years; n=77).

**Figure 1**: Flow diagram showing the numbers of Prevent Future Death reports (PFDs) included and excluded from the Preventable Deaths Database using the eligibility criteria for this study
Figure 2: Anticoagulants reported in cardiovascular disease-related Prevent Future Death reports (PFDs). *in these PFDs, the coroner suggested that if an anticoagulant had been used the death might have been prevented.

Seventy-five coroners across 36 jurisdictions wrote 113 PFDs. Coroners in the North West (25%) and South East (19%) of England wrote the most, whereas those in the East (2%) and North East (3%) of England wrote very few (Table 1).

Table 1: Jurisdictions of coroners who issued the 113 Prevent Future Death reports involving an anticoagulant and cardiovascular disease

| Region                                      | No. of cases (%) |
|---------------------------------------------|-------------------|
| **North West England**                      |                   |
| Greater Manchester                          | 20 (18)           |
| Blackpool & Fylde                          | 4 (4)             |
| Blackburn, Hyndburn & Ribble Valley        | 3 (3)             |
| Cumbria                                     | 1 (1)             |
| **South East England**                      |                   |

| Sunderland                                      | 3 (3) |
| East of England                                 | 2 (2) |
We identified 335 individual concerns raised by coroners in the 113 cases. Using content analysis, we categorised these concerns into 51 groups and five higher-order themes, including communication, failure to follow protocols, education and training, resources, and safety (Table 2). The most common concerns were poor systems (31%), poor communication (25%), failure to keep accurate medical records (25%), and failures or delays in having appropriate assessments done (17%). Concerns most frequently belonged to the theme of following protocols (36%), followed by communication (22%), and safety issues (21%).

### Table 2: Concerns raised by coroners, grouped by five higher-order themes, and how often they were reported

| Theme ( % of concerns) | Concern                                                                 | No. of cases (% ) |
|------------------------|-------------------------------------------------------------------------|-------------------|
| Failure to follow protocols (36%) | Failure/delay in appropriate assessments                              | 19 (17)           |
|                        | Failure to monitor treatment                                            | 15 (13)           |
|                        | Omission of necessary treatment                                         | 13 (12)           |
|                        | Delayed treatment                                                       | 12 (11)           |
|                        | Failure to review medicines                                             | 11 (10)           |
|                        | Failure to take a history or see the patient                            | 10 (9)            |
|                        | Failure/delay in performing necessary scans                             | 8 (7)             |
|                        | Failure to triage patients appropriately                               | 7 (6)             |
|                        | Failure to follow recommended practices                                 | 6 (5)             |
|                        | Failure to follow a protocol                                            | 6 (5)             |
|                        | Failure to review medical records                                       | 4 (4)             |
|                        | Failure to implement national guidelines                                | 3 (3)             |
|                        | Administration of drug in error                                         | 1 (1)             |
|                        | Failure to arrange supervision                                          | 1 (1)             |
|                        | Inability to care for both a patient’s physical and mental health       | 1 (1)             |
|                        | Management of medication for care home residents                        | 1 (1)             |
|                        | Medication administered despite known allergy                           | 1 (1)             |
| Communication (22%)    | Poor communication                                                      | 28 (25)           |
|                        | Failure to keep accurate medical records                                | 28 (25)           |
|                        | Failure to escalate deterioration in patient to the relevant medical professionals | 5 (4)          |
|                        | Failure to seek specialist advice when indicated                        | 4 (4)             |
|                        | Failure to follow the advice of a senior clinician                      | 2 (2)             |
|                        | Failure to warn of the consequences of not taking medication            | 2 (2)             |
| Category                           | Description                                                                 | Count (Percentage) |
|-----------------------------------|-----------------------------------------------------------------------------|--------------------|
| Safety (21%)                      | Poor systems                                                                | 35 (31)           |
|                                   | Discharge process                                                           | 16 (14)           |
|                                   | Non-robust investigation following the death                                | 15 (13)           |

In 82% of CVD-related PFDs involving anticoagulants, coroners stated that "action should be taken" (Supplementary Table 2). When coroners suggested further actions, we grouped their actions into 28 categories. Ensuring effective communication (3%), introducing new policies and protocols (2%), and reviewing the handling of prescriptions (2%) were the most common actions proposed (Supplementary Table 2).

For the 113 CVD-related PFDs involving anticoagulants, coroners sent 181 reports to individuals or organisations, collated into 37 groups (Table 3). NHS Trusts (29%), hospitals (10%), and general practices (8%) were addressed most frequently. By statute addressees must respond to the coroner within 56-days, but only 29% responded on time; 11%
responded late and 60% were overdue. Medical societies (0%) and royal colleges (0%) had the lowest response rates, while NHS entities had the highest, albeit with a collective response rate of 51%. Ranking recipients by response rate and response time, NHS 111, NHS Wales, and CCGs performed best (Supplement Table 3).

Table 3: Recipients of coroners Prevent Future Death reports (PFDs) and their response rates to reports

| Address | No. of reports received | No. of responses | Response rate (%) | Classification of responses | % On time | % Late | % Overdue |
|---------|-------------------------|-----------------|-------------------|-----------------------------|-----------|--------|----------|
| NHS entities | 118 | 60 | 51 | 38 | 13 | 49 |

### Discussion

**Summary**

We identified 113 premature deaths from cardiovascular disease involving anticoagulants. In 88% of cases, the use of one anticoagulant or more resulted in death. In 12% of cases, death was attributed to the absence of anticoagulation. We found wide geographical variation in the issuing of PFDs and the type of information reported, with coroners in Greater Manchester writing the most. Coroners raised many concerns, which we categorised into five themes: failure to follow protocols, communication, safety issues, education and training, and the lack of adequate resources. Most of these concerns were addressed locally and under regulation 28, 109 individuals or organisations were overdue in their response to such concerns.
Strengths and limitations

We used a reproducible data-collection method to examine all available PFDs from inception to 2019, which provided an estimated 40-fold time saving [20], and reduced the potential for selection bias. However, the PFDs included in our study depend on the working practices of coroners and the Chief Coroner’s Office in uploading PFDs and their responses to the website. The 113 PFDs cannot therefore represent all preventable deaths from CVD involving anticoagulants in England and Wales. There were also missing data; for example, 32% of PFDs did not report age and 16% did not specify the type of anticoagulant; this may be attributed to lack of PFD training provided to coroners.

Comparison with existing literature

Our study builds on prior research that evaluated smaller samples of coroners’ reports [15,24–27]. Compared with previous studies [26,28], we did not identify a sex imbalance. However, we found that most PFDs were addressed locally, as shown by Ferner et al. [15], which means that valuable lessons were not widely disseminated and may be why we found that coroners repeatedly expressed similar concerns, in line with former research [25]. This questions whether PFDs are fulfilling their purpose. Similar to Fox and Jacobson [26], we found pronounced geographical variation in the issuing of PFDs and poor response rates. A review of the coronial system in England and Wales highlighted lack of accountability, leadership, and quality assurance [29]. Since there is no system in place for enforcing or auditing compliance with regulation 28 or assessing the quality of PFDs and the adequacy of responses and actions taken to prevent deaths, our findings show that the system has scope for improvement. Fortunately, the value of PFDs as a tool for improving clinical practice is being recognised, and efforts are underway to widely disseminate these lessons to healthcare professionals, policymakers, and the public [30–34].

Implications for research and clinical practice

Concerns raised by coroners provide lessons for prescribers and policymakers on the safety and proper use of therapies. During the COVID-19 pandemic, patients were switched from warfarin to other oral anticoagulants, given the need for less frequent blood testing [35]. Drugs such as andexanet alfa could prove critical in the outcome of patients with severe bleeding during treatment with apixaban or rivaroxaban. Since the coroner expressed concerns (Case: 2018-0032), NICE has drafted an appraisal for andexanet alfa [36], and its publication is expected on 12 May 2021 [37]. There has also been a phased launch of
andexanet alfa in UK hospitals [38]. However, it is unclear whether this was a direct result of the PFD, since no response from the MHRA was published on the Judiciary website.

When PFDs are addressed to the appropriate recipients at the national level, their actions can help prevent deaths. For example, a PFD was sent to NICE when the deceased suffered a fall while taking an anticoagulant without having the appropriate neuroimaging performed (Case: 2019-0106). The coroner's concerns were acknowledged in a NICE surveillance report [39] and resulted in updating of the NICE guideline on head injury, to emphasise that people taking DOACs should be investigated with the same care as those taking warfarin [40]. However, we also identified unaddressed concerns about national guideline; three-quarters of PFDs sent to NICE have no responses listed on the Judiciary website. Restarting warfarin after a head injury is particularly important, as delays could leave the patient at risk of a stroke, but resuming too soon may lead to haemorrhage. A retrospective review of the medical charts of 256 patients admitted to a trauma centre in West Texas between 2009 and 2012 showed that patients who resumed anticoagulant therapy at 7-10 days after the injury had the best prognosis [41]. PFDs can therefore be used to update guidance and inform future prospective cohort studies.

Our study provides a database and resource (https://preventabledeathstracker.net/) for future evaluations of PFDs. Further content analysis should be used to assess the 181 responses to the 113 PFDs, to assess the adequacy of actions taken or proposed to prevent deaths. Future research could use our open data to examine coroners' concerns in the 546 CVD-related PFDs not involving anticoagulants and their responses. In building the web scraper to collect PFDs, we found various inconsistencies and omissions on the Judiciary website, which should be addressed to improve the quality of the data. The missing data from PFDs we have highlighted reveal target areas for coronial training in the writing of PFDs.

**Conclusions**

PFDs provide valuable lessons when prescribing anticoagulants and managing patients with CVD. However, it is unclear whether actions are being taken to incorporate such lessons. To improve patient safety, PFDs should be widely disseminated.
Funding: No funding was obtained to undertake this study.

Ethical approval: As the case reports are publicly available on the Judiciary website, approval from an ethics committee was not required.

Contributions: AA proposed the topic for research, contributed to the protocol and devised the algorithm for the eligibility of cases, screened the database for eligible case reports, extracted and analysed the data, and wrote the first draft of the manuscript. GCR designed the study, wrote the protocol, sourced the data, contributed to the web scraper, provided data management, dual screened the database for eligible cases, analysed the data, provided primary supervisory support and substantiality contributed to subsequent manuscript drafts. JKA and CH reviewed the protocol and preliminary findings and provided supervisory support. NJD wrote the code and advised on the web scraper. All authors have full access to all the data in the study, read and approved the final manuscript, and accept responsibility to submit for publication.

Data availability: Study materials, protocol, data, and statistical code are openly available on the OSF (https://osf.io/qkfjp/) and GitHub (https://github.com/georgiarichards/CVD_anticoags).

Competing interests: AA has no competing interest to disclose. CH is a National Institute for Health Research (NIHR) Senior Investigator and has received expenses and fees for his media work, received expenses from the World Health Organisation (WHO), Food and Drug Administration (FDA), and holds grant funding from the NIHR School for Primary Care Research (SPCR), and the NIHR SPCR Evidence Synthesis Working Group [Project 380], the NIHR BRC Oxford and the WHO. On occasion, CH receives expenses for teaching EBM and is also paid for his GP work in NHS out of hours (contract with Oxford Health NHS Foundation Trust). CH is the Director of the CEBM. JKA has published articles and edited textbooks on adverse drug reactions and interactions and has often given medicolegal advice, including appearances as an expert witness in coroners’ courts, dealing with the adverse effects of drugs. NJD has no conflicts related to the submitted work. Outside the submitted work, he declares a doctoral studentship from the Naji Foundation, grant funding from the Fetzer Franklin Memorial Fund, and employment on grants from the Laura and John Arnold Foundation, The Good Thinking Society, and the German Federal Ministry of Education and
Research (BMBF). GCR was financially supported by the NIHR SPCR, the Naji Foundation, and the Rotary Foundation to study for a Doctor of Philosophy (2017-2020) but no longer has any financial COIs. GCR is an Associate Editor of BMJ Evidence Based Medicine. The views expressed are those of the authors and not necessarily those of the NHS, the NIHR, or the Department of Health and Social Care.
