Landau damping effects on dust-acoustic solitary waves in a dusty negative-ion plasma

Arnab Barman¹ and A. P. Misra¹

¹Department of Mathematics, Siksha Bhavana, Visva-Bharati University, Santiniketan-731 235, West Bengal, India

The nonlinear theory of dust-acoustic waves (DAWs) with Landau damping is studied in an unmagnetized dusty negative-ion plasma in the extreme conditions when the free electrons are absent. The cold massive charged dusts are described by fluid equations, whereas the two-species of ions (positive and negative) are described by the kinetic Vlasov equations. A Korteweg de-Vries (KdV) equation with Landau damping, governing the dynamics of weakly nonlinear and weakly dispersive DAWs, is derived following Ott and Sudan [Phys. Fluids 12, 2388 (1969)]. It is shown that for some typical laboratory and space plasmas, the Landau damping (and the nonlinear) effects are more pronounced than the finite Debye length (dispersive) effects for which the KdV soliton theory is not applicable to DAWs in dusty pair-ion plasmas. The properties of the linear phase velocity, solitary wave amplitudes (in presence and absence of the Landau damping) as well as the Landau damping rate are studied with the effects of the positive ion to dust density ratio (µpd) as well as the ratios of positive to negative ion temperatures (σ) and masses (m).

I. INTRODUCTION

Plasmas with massive charged dust grains are of interest both for space (e.g., cometary tails, planetary rings, the interstellar medium, Earth’s magnetosphere and upper atmosphere, Earth’s D and lower E regions etc.) as well as laboratory plasmas [2,3]. Furthermore, dusty plasmas containing both positive and negative ions and a very few percentage of free electrons (or almost electron-free) are found in both naturally occurring plasmas (e.g., Earth’s D and lower E regions, the F-ring of Saturn, nighttime polar mesosphere etc.) [2,4,5] and in plasmas used for technological applications [6,7]. There are several motivations for investigating such plasmas and associated waves and instabilities owing to their potential applications in both laboratory and space plasma environments (See, e.g., Refs. 8,16). In dusty plasmas, the size of the dust grains may vary in the range of 0.05 – 10µm, their mass is about 10^6 – 10^12 times the mass of ions and they have atomic numbers z_d in the range of 10^3 – 10^5 [1]. In typical dusty plasmas with electrons and ions, dust grains are negatively charged due to high mobility of electrons into dust grain surface [1]. However, recent laboratory experiments [8,10] suggest that in dusty negative-ion plasmas where positive ions are the more mobile species, dusts can be positively charged when m_n > m_p, n_n > n_e and T_p > T_n are satisfied, where m_j is the mass, n_j is the number density and T_j is the thermodynamic temperature of j-species particles in which j = e, p, n stand for electrons, positive ions and negative ions respectively. On the other hand, when charged dust grains collect all the electrons from the background plasma, they can be negatively charged. Such density depletion of electrons associated with the capture of electrons by aerosol particles have been observed in the summer polar mesosphere at about 85 km altitude [17]. Furthermore, positively charged nanometer-seized particles were observed in the nighttime polar mesosphere in a region (Altitude range between 80 and 90 km) dominated by positive and negative ions and a very few percentage of electrons [5].

It has been found that the presence of charged dust grains modifies the plasma wave phenomena and these charged dust grains give rise to new low-frequency eigen-modes, called dust-acoustic wave (DAW), which was first theoretically predicted by Rao et al. [18]. However, the presence of negative ions in dusty plasmas can significantly modify not only the dispersion properties of DAWs but also some nonlinear localized structures (For some recent theoretical developments and experiments in negative ion plasmas readers are referred to Refs. 11-14). On the other hand, these waves can be damped (collisionless) due to the resonance of particles (trapped and/or free) with the wave (i.e., when the particle’s velocity is nearly equal to the wave phase velocity) [19]. The linear electron Landau damping of nonlinear ion-acoustic solitary waves was first studied by Ott and Sudan [20,21] neglecting the particle’s trapping effects on the assumption that the particle trapping time is much longer than that of Landau damping. They derived a Korteweg-de Vries (KdV) equation with a source term that models the lowest-order effects of resonant particles. It was demonstrated that an initial wave form may either steepen or not depending on the relative size of the nonlinearity compared to the Landau damping. The latter was also shown to cause decay of wave amplitude with time.

In the past, several authors have attempted to study the effects of Landau damping on the nonlinear propagation of electrostatic solitary waves in different plasma systems. For example, Bandyopadhyay et al. [22,23] investigated the propagation characteristics of ion-acoustic solitary waves with Landau damping in nonthermal plasmas. Ghosh et al. [24] considered the linear Landau damping effects on nonlinear ion-acoustic solitary waves.
in electron-positron-ion plasmas. They studied the properties of the wave phase velocity, the solitary wave amplitude as well as the Landau damping rate with the important effects of positron density and temperature. Motivated by the recent theoretical developments as well as experimental observations of low-frequency electrostatic waves in pair-ion plasmas [8-10], we have investigated the Landau damping effects of dust-acoustic (DA) solitary waves in dusty pair-ion plasmas (quite distinctive from electron-positron-ion plasmas and dusty electron-ion plasmas). We show that for typical plasma parameters relevant for laboratory and space environments, the Landau damping (and the nonlinear) effect is stronger than the finite Debye length (dispersive) effects for which the KdV soliton theory is not applicable to DAWs in dusty pair-ion plasmas. The Landau damping effect is shown to slow down the wave amplitude with time. It is found that in contrast to electron-ion or electron-positron-ion plasmas, the nonlinearity in the KdV equation can never vanish in dusty pair-ion plasmas with positively or negatively charged dusts. This implies that the modified KdV equation is no longer required for the evolution of DAWs. The properties of the linear phase velocity, solitary wave amplitudes (in presence and absence of the Landau damping) as well as the Landau damping rate are also analyzed with the effects of positive ion to dust density ratio ($\mu_{pd}$) as well as the ratios of positive to negative ion temperatures ($\sigma$) and masses ($m$).

II. BASIC EQUATIONS

We consider the nonlinear propagation of electrostatic DAWs in an unmagnetized collisionless dusty plasma consisting of singly charged adiabatic positive and negative ions, and positively or negatively charged mobile dusts. The latter are assumed to have equal mass and charge which are treated as constant. It is to be noted that the dust charge fluctuation process may introduce a new low-frequency wave eigen mode as well as another dissipative effect (wave damping) into the system. However, we have neglected this charge fluctuation effect on the propagation of dust-acoustic waves by the assumption that the charging rate of dust grains is very high compared to the dust plasma oscillation frequency. The collisions of all particles are also neglected in the considered interval of time. Furthermore, in dusty plasmas the ratio of electric charge to mass of dust grains remains much smaller than those of both positive and negative ions. It is also assumed that the size of the grains is small compared to the average distance between them. The unperturbed state is overall neutral so that the internal electric field is zero. Also, the curl of the electric field vanishes (i.e., electrostatic), and the perturbation about the equilibrium state is weak. At equilibrium, the overall charge neutrality condition reads

$$n_{p0} + \zeta d n_{d0} = n_{n0},$$

where $n_{j0}$ is the unperturbed number density of species $j$ ($j=p, n, d$ respectively stand for positive ions, negative ions, and dynamical charged dusts), $\zeta d (> 0)$ is the unperturbed dust charge state and $\zeta = \pm 1$ according to when dusts are positively or negatively charged.

The cold dust is described by a set of fluid equations [2-4], whereas the two species of ions (positive and negative) are described by the kinetic Vlasov equation [7]. The electric potential $\phi$ is described by the Poisson equation [9]. Thus, the basic equations for the dynamics of charged particles in one space dimension are

$$\frac{\partial n_d}{\partial t} + \frac{\partial (n_d u_d)}{\partial x} = 0,$$  

$$\frac{\partial u_d}{\partial t} + u_d \frac{\partial u_d}{\partial x} = - \frac{q_d}{m_d} \frac{\partial \phi}{\partial x},$$  

$$\frac{\partial f_j}{\partial t} + v_j \frac{\partial f_j}{\partial x} - q_j \frac{\partial \phi}{\partial x} = 0,$$  

$$\frac{\partial^2 \phi}{\partial x^2} = -4\pi e(n_p - n_n + \zeta d n_d),$$

where $j$ stands for $p, n$ denoting, respectively, the positive and negative ions. The ion densities are given by

$$n_j = \int_{-\infty}^{\infty} f_j dv.$$  

In equations (2-6), $n_d, u_d, q_d(= \pm z_d e), m_d$, respectively, denote the number density, fluid velocity, charge and mass of dust grains. Also, $v$ is the particle’s velocity, and $f_j, m_j$ and $n_j$, respectively, denote the velocity distribution function, mass and number densities of $j$-species ions. Furthermore, $\phi$ is the electrostatic potential and $x$ and $t$ are the space and time coordinates.

Equations (2)-(6) can be recast in terms of dimensionless variables. We normalize the physical quantities according to $u_d \rightarrow u_{d/e}$, $\phi \rightarrow e\phi/k_B T_p$, $n_j \rightarrow n_j/n_{p0}$, $n_d \rightarrow n_d/n_{d0}$, $f_j \rightarrow f_j v_{tj}/n_{j0}$, $v \rightarrow v/v_{tp}$, where $c_s = \sqrt{z_d k_B T_p/m_d} = \omega_{pd}\lambda_D$ is the DA speed with $\omega_{pd} = \sqrt{4\pi n_{d0} z_d^2 e^2/m_d}$ and $\lambda_D = \sqrt{k_B T_p/4\pi n_{d0} z_d^2 e^2}$ denoting, respectively, the dust plasma frequency and the plasma Debye length. Here, $k_B$ is the Boltzmann constant, $T_j$ is the thermodynamic temperature and $v_{tj}(= \sqrt{k_B T_j/n_{j0}})$ is the thermal velocity of $j$-species ions. The space and time variables are normalized by $L$ and $L/c_e$, respectively, where $L$ is the characteristic scale length for variations of $n_j, u_d, \phi, f_j$ etc.

Thus, from equations (2-6), we obtain the following set of equations in dimensionless form:

$$\frac{\partial n_d}{\partial t} + \frac{\partial (n_d u_d)}{\partial x} = 0,$$  

$$\frac{\partial u_d}{\partial t} + u_d \frac{\partial u_d}{\partial x} = -\zeta \frac{\partial \phi}{\partial x}. $$
The wave dispersion due to deviation from the quasineutrality. This measures the strength of the nonlinearities of all physical quantities should vanish. Thus, for a finite \( \epsilon \) with \( 0 < \epsilon < 1 \), we can expect slow variations of the wave amplitude in the moving frame of reference, and so introduce the stretched coordinates as \[ \xi = \epsilon^{1/2}(x - Mt), \quad \tau = \epsilon^{3/2}t, \quad (16) \]
where \( M \) is the nonlinear wave speed (relative to the frame) normalized by \( c_s \), to be shown to be equal to \( v_p \) later.

The dependent variables are expanded in powers with respect to \( \epsilon \) about the equilibrium state as:

\[ n_d = 1 + \alpha_2 c_n^{(1)} + \alpha_2^2 c_n^{(2)} + \cdots, \]
\[ u_d = \alpha_2 e_u^{(1)} + \alpha_2^2 e_u^{(2)} + \cdots, \]
\[ f\equiv f^{(0)} + \alpha_2 f^{(1)} + \alpha_2^2 f^{(2)} + \cdots, \quad (17) \]

where \( f_j^{(0)} \), for \( j = p, n \), are assumed to be the Maxwellian given by

\[ f_j^{(0)} = \frac{1}{\sqrt{2\pi}} \exp \left\{ \left(m_j T_p / m_p T_d \right)(-\nu^2/2) \right\}. \quad (18) \]

For convenience, we temporarily drop the constant \( \alpha_2 \) in the subsequent expressions and equations. We, however, remember that \( \alpha_1, \alpha_2 \) and \( \alpha_3 \) will explicitly appear in the coefficients of the terms associated with the Landau damping, nonlinear and the dispersion in the KdV equation. In what follows, we substitute the expressions from Eqs. (16) and (17) into Eqs. (7), (8), (10), (11), (13) and (14) and equate successively different powers of \( \epsilon \). The results are given in the following subsections.

**First-order perturbations and nonlinear wave speed**

Equating the coefficients of \( \epsilon^{3/2} \) from Eqs. (7) and (8), the coefficients of \( \epsilon \) from Eqs. (10) and (11), and the coefficients of \( \epsilon^3 \) from Eqs. (13) and (14), we successively obtain

\[ n_d^{(1)} = u_n^{(1)}/M, \quad (19) \]
\[ u_d^{(1)} = \zeta \phi^{(1)} / M. \]  
\[ 0 = \mu_{nd} n_n^{(1)} - \mu_{pd} n_p^{(1)} - \zeta n_d^{(1)}, \]  
\[ n_j^{(1)} = \sqrt{\frac{m_j}{m_p} \frac{T_p}{T_j}} \int_{-\infty}^{\infty} f_j^{(1)} dv, \]  
\[ v \frac{\partial f_p^{(1)}}{\partial \xi} + v f_p^{(0)} \frac{\partial \phi^{(1)}}{\partial \xi} = 0, \]  
\[ \frac{v \partial f_n^{(1)}}{\partial \xi} - \sigma_v f_n^{(0)} \frac{\partial \phi^{(1)}}{\partial \xi} = 0. \]  
From Eqs. (19), (20) we obtain
\[ n_d^{(1)} = \zeta \phi^{(1)} / M^2. \]  
Equation (23) yields
\[ \frac{\partial f_p^{(1)}}{\partial \xi} = -f_p^{(0)} \frac{\partial \phi^{(1)}}{\partial \xi} + \lambda(\xi, \tau) \delta(v), \]  
where \( \delta(v) \) is the Dirac delta function and \( \lambda(\xi, \tau) \) is an arbitrary function of \( \xi \) and \( \tau \). We find that the above solution for \( \partial f_p^{(1)}/\partial \xi \) involves the arbitrary function \( \lambda(\xi, \tau) \), and hence is not unique. Thus, for the unique solution to exist we follow Ref. [20] and include an extra higher-order term \( \epsilon^{5/2} \alpha_1 \left( \partial f_p^{(1)}/\partial \tau \right) \) originating from the term \( \epsilon^{5/2} \alpha_1 \left( \partial f_p^{(1)}/\partial \tau \right) \) in Eq. (16) after the expressions (16) and (17) being substituted. Thus, we write Eq. (23) as
\[ \alpha_1 \epsilon^2 \frac{\partial f_p^{(1)}}{\partial \tau} + \frac{\partial f_p^{(1)}}{\partial \tau} = -v f_p^{(0)} \frac{\partial \phi^{(1)}}{\partial \xi}, \]  
Similarly, from Eq. (24), we have
\[ \alpha_1 \epsilon^2 \frac{\partial f_n^{(1)}}{\partial \tau} + \frac{\partial f_n^{(1)}}{\partial \tau} = \sigma_v f_n^{(0)} \frac{\partial \phi^{(1)}}{\partial \xi}. \]  
The solutions of the initial value problems (27) and (28) are now unique, and can be found uniquely, once \( f_j^{(1)} \) for \( j = p, n \) are known, by letting \( \epsilon \rightarrow 0 \) as
\[ f_j^{(1)} = \lim_{\epsilon \rightarrow 0} f_j^{(1)}. \]  
Next, taking the Fourier transform of Eq. (27) with respect to \( \xi \) and \( \tau \) according to the formula
\[ \hat{f}(\omega, k) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(\xi, \tau) e^{i(k\xi - \omega\tau)} d\xi d\tau, \]  
we obtain
\[ \hat{f}_p^{(1)} = -\left( \frac{k\nu f_p^{(0)}}{k\nu - \epsilon^2 \alpha_1 \omega} \right) \hat{\phi}^{(1)}. \]  
We note that the singularity appears in Eq. (31). In order to avoid it we replace \( \omega \) by \( \omega + i\eta \), where \( \eta > 0 \), to obtain
\[ \hat{f}_p^{(1)} = -\left[ \frac{k\nu f_p^{(0)}}{(k\nu - \epsilon^2 \alpha_1 \omega) - i\eta \alpha_1 \epsilon^2} \right] \hat{\phi}^{(1)}. \]  
Proceeding to the limit as \( \epsilon \rightarrow 0 \) and using the Plemelj’s formula
\[ \lim_{\epsilon \rightarrow 0} \frac{1}{x + i\epsilon} = -i\pi \delta(x) + P \left( \frac{1}{x} \right), \]  
where \( P \) and \( \delta \), respectively, denote the Cauchy principal value and the Dirac delta function, we obtain
\[ \hat{f}_p^{(1)} = -f_p^{(0)} \hat{\phi}^{(1)}, \]  
and in which we have used the properties \( xP(1/x) = 1, x\delta(x) = 0 \). Next, taking Fourier inversion of Eq. (34), we have
\[ f_p^{(1)} = -f_p^{(0)} \phi^{(1)}. \]  
Proceeding in the same way as above for the positive ions, we obtain from Eq. (28) for negative ions as
\[ f_n^{(1)} = \sigma f_n^{(0)} \phi^{(1)}. \]  
From Eqs. (35) and (36) and using Eq. (22) we obtain
\[ n_d^{(1)} = -\phi^{(1)}, \]  
\[ n_n^{(1)} = \sigma \phi^{(1)}. \]  
Substituting the expressions for \( n_j^{(1)} \) from Eqs. (25), (37), and (38) into Eq. (21), we obtain the following expression for the nonlinear wave speed
\[ M = (\mu_{pd} + \sigma \mu_{nd})^{-1/2} \equiv [(1 + \sigma) \mu_{pd} \pm \sigma]^{-1/2}. \]  
As expected, the expression for \( M \) is the same as obtained in the linear dispersion law (15) for plane wave perturbations. The signs \( \pm \) stand for the expressions according to when dust grains are considered positive or negative. For typical laboratory [8] and space plasma parameters [9], \( \sigma \gtrsim 1 \). Also, for plasmas with positively or negatively charged dusts, the expression inside the square root is positive and/or \( \mu_{pd} > 1 \). So, \( M < 1 \), i.e., the nonlinear wave speed is always lower than the dust-acoustic speed. Figure 1 shows that for plasmas with positively charged dusts (See the solid, dashed and dotted lines) the value of \( M \) tends to decrease with increasing values of the positive to negative ion temperature ratio \( \sigma \) as well as the density ratio \( \mu_{pd} \). However, the value of \( M \) becomes higher in the case of negatively charged dusts (Compare the solid and the dash-dotted lines).
obtain the coefficients of the coefficients shown in the figure. The acronym PCD (NCD) stands for the σ (39) is plotted against the temperature ratio FIG. 1. The phase velocity of the nonlinear DAW [Eq. \[\text{Eq. (40)}\] is plotted against the temperature ratio \(\sigma \) \(=T_p/T_n\) for different values of the density ratio \(\mu_{pd} = n_{pd}/\varepsilon n_{do}\) as shown in the figure. The acronym PCD (NCD) stands for the case of positively (negatively) charged dusts.

Second-order perturbations

Equating the coefficients of \(\varepsilon^{5/2}\) from Eqs. (7) and (8), the coefficients of \(\varepsilon^2\) from Eqs. (10) and (11), and the coefficients of \(\varepsilon^5/2\) from Eqs. (13) and (14), we successively obtain

\[
-M \frac{\partial n_d^{(2)}}{\partial \xi} + \frac{\partial u_d^{(2)}}{\partial \xi} + \frac{\partial n_d^{(1)}}{\partial \tau} + \frac{\partial (u_d^{(1)} n_d^{(1)})}{\partial \xi} = 0, \quad (40)
\]

\[
-M \frac{\partial u_d^{(2)}}{\partial \xi} + \frac{\partial u_d^{(1)}}{\partial \xi} + \frac{\partial n_d^{(1)}}{\partial \tau} = -\zeta \frac{\partial \phi^{(2)}}{\partial \xi}, \quad (41)
\]

\[
\frac{\partial^2 \phi^{(1)}}{\partial \xi^2} = \mu_{nd} n_d^{(2)} - \mu_{pd} u_d^{(2)} - \zeta n_d^{(2)}, \quad (42)
\]

\[
n_j^{(2)} = \sqrt{m_j T_p T_j} \int_{-\infty}^{\infty} f_j^{(2)} dv, \quad (43)
\]

\[
-\alpha_1 M \frac{\partial f^{(1)}_p}{\partial \xi} + v \frac{\partial f^{(2)}_p}{\partial \xi} + \frac{\partial \phi^{(1)}}{\partial \xi} \frac{\partial f^{(1)}_p}{\partial \xi} + v f^{(0)}_p \frac{\partial \phi^{(2)}}{\partial \xi} = 0, \quad (44)
\]

Substituting the expressions for \(f_j^{(2)}\) from Eqs. (35) and (36) into Eqs. (44) and (45) we successively obtain

\[
\frac{v}{\partial \xi} f^{(2)}_p + v f^{(0)}_p \frac{\partial \phi^{(2)}}{\partial \xi} = (D_{pa} + v D_{pb}) f^{(0)}_p, \quad (46)
\]

\[
\frac{v}{\partial \xi} f^{(2)}_n - \sigma v f^{(0)}_n \frac{\partial \phi^{(2)}}{\partial \xi} = (D_{na} + v D_{nb}) f^{(0)}_n, \quad (47)
\]

where

\[
D_{pa} = -\alpha_1 M \frac{\partial \phi^{(1)}}{\partial \xi}, \quad D_{pb} = \frac{1}{2} \frac{\partial (\phi^{(1)})^2}{\partial \xi},
\]

\[
D_{na} = \alpha_1 M \frac{\partial \phi^{(1)}}{\partial \xi}, \quad D_{nb} = \frac{1}{2} \frac{\sigma (\phi^{(1)})^2}{\partial \xi}. \quad (48)
\]

As before, to get the unique solutions for \(f_j^{(2)}\) for positive \((j = p)\) and negative \((j = n)\) ions, we introduce an extra higher-order term \(\varepsilon^{9/2} \alpha_1 \left( \frac{\partial f_j^{(1)}}{\partial \tau} \right)\) originating from the term \(\varepsilon^{5/2} \alpha_1 \left( \frac{\partial f_j^{(1)}}{\partial \tau} \right)\) in Eqs. (13) and (14) after the expressions (16) and (17) being substituted. Thus, we rewrite Eqs. (49) and (50) as

\[
\alpha_1 e^{i \frac{\partial f^{(2)}_p}{\partial \tau}} - v \frac{\partial f^{(2)}_p}{\partial \xi} + v f^{(0)}_p \frac{\partial \phi^{(2)}}{\partial \xi} = (D_{pa} + v D_{pb}) f^{(0)}_p, \quad (49)
\]

\[
\alpha_1 e^{i \frac{\partial f^{(2)}_n}{\partial \tau}} - v \frac{\partial f^{(2)}_n}{\partial \xi} - \sigma v f^{(0)}_n \frac{\partial \phi^{(2)}}{\partial \xi} = (D_{na} + v D_{nb}) f^{(0)}_n. \quad (50)
\]

So, the unique solutions can be found, once \(f_j^{(2)}\) for \(j = p, n\) are known, by letting \(\epsilon \to 0\) as

\[
f_j^{(2)} = \lim_{\epsilon \to 0} f_j^{(2)}. \quad (51)
\]

Next, introducing the Fourier transform in Eq. (49) with respect to \(\xi\) and \(\tau\) according to the formula (30), we have

\[
\hat{f}^{(2)}_p = -\frac{k v f^{(0)}_p}{k v - \varepsilon^2 \alpha_1 \omega} \hat{\phi}^{(2)} - i \left( \frac{\hat{D}_{pa} + v \hat{D}_{pb}}{k v - \varepsilon^2 \alpha_1 \omega} \right) f^{(0)}_p. \quad (52)
\]

As before, to avoid the wave singularity, \(\omega\) will have a small positive imaginary part. So, we replace \(\omega\) by \(\omega + i \eta\), where \(\eta > 0\), to obtain from Eq. (52) as

\[
\hat{f}^{(2)}_p = \left[ \frac{k v f^{(0)}_p}{(k v - \varepsilon^2 \alpha_1 \omega) - i \eta \alpha_1 \omega^2} \right] \hat{\phi}^{(2)} - i \left[ \frac{(\hat{D}_{pa} + v \hat{D}_{pb}) f^{(0)}_p}{(k v - \varepsilon^2 \alpha_1 \omega) - i \eta \alpha_1 \omega^2} \right] f^{(0)}_p. \quad (53)
\]
we have from Eq. (56). Then using the convolution theorem of Fourier transform, we obtain from Eq. (50) for negative ions as

\[
\begin{aligned}
\frac{\partial n_p}{\partial \xi} + \frac{\partial \phi}{\partial \xi} &= \frac{1}{2} \frac{\partial \phi^{(1)}(\xi)}{\partial \xi} \\
+ \alpha_1 M \frac{1}{\sqrt{2\pi}} P \int_{-\infty}^{\infty} \frac{\partial \phi^{(1)}(\xi)}{\partial \xi'} d\xi',
\end{aligned}
\]

(57)

where we have used \( F^{-1}[i \text{ sgn}(k)] = -(1/\pi) P (1/\xi) \).

Proceeding in the same way as above for positive ions, we obtain from Eq. (56) for negative ions as

\[
\begin{aligned}
\frac{\partial n_p}{\partial \xi} - \sigma \frac{\partial \phi}{\partial \xi} &= \frac{\sigma^2}{2} \frac{\partial \phi^{(1)}(\xi)}{\partial \xi} \\
- \alpha_1 M n^{1/2} \sigma^{3/2} \frac{1}{\sqrt{2\pi}} P \int_{-\infty}^{\infty} \frac{\partial \phi^{(1)}(\xi)}{\partial \xi'} d\xi',
\end{aligned}
\]

(58)

The Fourier inverse transform of Eq. (55) yields

\[
\begin{aligned}
i k \left( \hat{n}_p^{(2)} + \hat{\phi}^{(2)} \right) &= \hat{D}_{pa} + i \sqrt{\frac{\pi}{2}} \text{ sgn}(k) \hat{D}_{pa}.
\end{aligned}
\]

(55)

The Fourier inverse transform of Eq. (55) yields

\[
\begin{aligned}
\frac{\partial n_p^{(2)}}{\partial \xi} + \frac{\partial \phi^{(2)}}{\partial \xi} &= \frac{1}{2} \frac{\partial (\phi^{(1)})^2}{\partial \xi} \\
+ \sqrt{\frac{\pi}{2}} F^{-1} \left[ i \text{ sgn}(k) \hat{D}_{pa} \right].
\end{aligned}
\]

(56)

KdV Equation with Landau damping

In order to obtain the required KdV equation, we first eliminate \( \partial u_d^{(2)}/\partial \xi \) and \( \partial n_d^{(2)}/\partial \xi \) from Eqs. (40)-(42) and then eliminate \( \partial n_d^{(2)}/\partial \xi \) by using Eqs. (57) and (58). In the resulting equation we also substitute the expressions for \( n_d^{(1)} \) and \( u_d^{(1)} \) from Eqs. (19) and (20). Thus, we obtain the following KdV equation (Recall that the constants \( \alpha_1, \alpha_2 \) and \( \alpha_3 \) will enter into the Landau damping, nonlinear and the dispersive terms)

\[
\frac{\partial n}{\partial \tau} + a P \int_{-\infty}^{\infty} \frac{\partial n}{\partial \xi} d\xi' + b n \frac{\partial n}{\partial \xi} + c \frac{\partial^3 n}{\partial \xi^3} = 0,
\]

(59)

where \( n = n_d^{(1)} \) and the coefficients of the Landau damping, nonlinear and dispersive terms, respectively, are

\[
a = \frac{\alpha_1}{\sqrt{8\pi} \sigma_1^{1/2}} \left[ \zeta \sqrt{m + \left( \sqrt{m} + \sigma_1^{-3/2} \right)} \mu_{pd} \right],
\]

(60)

\[
b = \frac{\alpha_2}{2\sqrt{\sigma_1}} \left[ 3 - \zeta \frac{\sigma_2}{\sigma_1} \right],
\]

(61)

\[
c = \frac{\alpha_3}{2} \left( \sigma_1 \right)^{-3/2},
\]

(62)

with \( \sigma_1 = \zeta + (1 + \sigma_1) \mu_{pd}, \sigma_2 = \zeta + (1 - \sigma_2) \mu_{pd} \) and \( \zeta = \pm 1 \) denoting, respectively, for positively and negatively charged dusts.
FIG. 3. The KdV soliton solution \( n \) [Eq. (66)] is shown with respect to \( \xi \) at \( \tau = 0 \) for different values of (a) the temperature ratio \( \sigma = T_p/T_n \) (left panel) and (b) the density ratio \( \mu_{pd} = n_{pd}/n_{d0} \) (right panel), keeping one parameter fixed at a time, as in the figure. The acronym PCD (NCD) stands for the case of positively (negatively) charged dusts.

Equation (59) is the required KdV equation which describes the weakly nonlinear and weakly dispersive dust-acoustic waves in an unmagnetized dusty pair-ion plasma with the effects of Landau damping. Inspecting on the coefficients \( a, b \) and \( c \) we find that for \( \sigma > 1 \) and \( \alpha_1, \alpha_2, \alpha_3 \sim O(1) \), we have \( \sigma_1 \gtrsim \sigma_2 \) and \( b > a, c \) for typical laboratory \([3, 8, 9]\) and space \([5]\) plasma parameters. Also, if we set \( \delta = 0 \), i.e. if we neglect the strength of the Landau damping associated with the ions then Eq. (59) reduces to the usual KdV equation which governs the small but finite amplitude nonlinear DAWs in unmagnetized dusty pair-ion plasmas.

It is of interest to examine the range of values of the parameters for which the KdV equation (without the Landau damping) is applicable to DAWs, and also to see the competition between nonlinearity and Landau damping in determining whether or not an initial wave steepens. To this end we consider typical plasma parameters that are relevant to laboratory and space plasmas. For example, for laboratory plasmas \([2, 8, 9]\) (in which the light positive ions are singly ionized potassium \( K^+ \) and heavy negative ions are \( SF_6^- \)), we can consider \( m_p = 6.5 \times 10^{-23} \text{g}, m_n = 2.4 \times 10^{-22} \text{g}, T_p = 0.2 \text{eV} = 2321 \text{K}, T_n = 0.025 \text{eV} = 290.12 \text{K}, n_{d0} = 2 \times 10^9 \text{cm}^3, \) \( n_{p0} = 1.3 \times 10^9 \text{cm}^{-3}, z_{pd} = 2 \times 10^6 \text{cm}^{-3}, \phi_s = 0.1 \) \( \nu = 3 \times 10^{-4} \text{statv}, R = 5.04 \mu \text{m} = 5.04 \times 10^{-4} \text{cm} \) and \( z_d = R\phi_s/e \sim 350 \), so that we have [Assuming that \( \alpha_1, \alpha_2, \alpha_3 \sim O(1) \) \( a = 0.0412 \) (0.1028), \( b = 0.2719 \) (0.6263) and \( c = 0.0041 \) (0.0194) for positively (negatively) charged dusts]. This implies that the nonlinear and the Landau damping are larger than the finite Debye length (dispersive) effects so that the KdV soliton theory is not applicable to DAWs. This is, in fact, true for the experiment described in Ref. \([22]\). On the other hand, for space plasma parameters \([5]\) (e.g., a dusty region at an altitude of about 95 km) in which \( m_p = 28m_{\text{proton}} = 4.7 \times 10^{-23} \text{g}, m_n = 300m_{\text{proton}} = 5.02 \times 10^{-22} \text{g}, T_p = 200 \text{K}, T_n = 200 \text{K}, n_{d0} = 2 \times 10^6 \text{cm}^{-3}, n_{p0} = 10^6 \text{cm}^{-3}, z_{pd} = 10^6 \text{cm}^{-3}, \phi_s = 0.7 \) \( \nu = 2.3 \times 10^{-3} \text{statv}, R = 0.6 \text{nm} \) \( = 6 \times 10^{-8} \text{cm}, \) we have [Assuming that \( \alpha_1, \alpha_2, \alpha_3 \sim O(1) \) \( a = 0.1670 \) (0.1995), \( b = 0.8340 \) (1) and \( c = 0.09 \) (0.5) for positively (negatively) charged dusts. In this case, though the Landau damping coefficient is lower than the nonlinear one, but it is larger than or comparable with the dispersive coefficient. Thus, both in laboratory and space plasma environments the Landau damping effects on DAWs can no longer be negligible, but may play crucial roles in reducing the wave amplitude which will be shown shortly.

Next, to obtain the regular Landau damping of DAWs in plasmas we set \( b = c = 0 \). Then Eq. (59) reduces to

\[
\frac{\partial n}{\partial \tau} + aP \int_{-\infty}^{\infty} \frac{\partial n}{\partial \xi} \frac{d\xi'}{\xi - \xi'} = 0. \tag{63}
\]

Taking the Fourier transform of Eq. (63) according to the formula \([30]\) and using the result that the inverse transform of \([i \text{sgn}(k)]\) is \(-(1/\pi)P (1/\xi)\), we have

\[
\omega = -i\kappa a_1 \sqrt{\frac{\pi \sigma^{-1/2}}{8 \sigma_1^2}} \left[ \zeta \sqrt{m} + (\sqrt{m} + \sigma^{-3/2})\mu_{pd} \right] = -i\pi \kappa a. \tag{64}
\]

Thus, the DAWs become damped due to the finite positive and negative ion inertial effects as \( \alpha_1 \sim \sqrt{m_j/m_d} \), and the damping decrement (nondimensional) \( \gamma \) is given by

\[
|\gamma| \sim \sqrt{\frac{m_p z_d}{m_d}} \sqrt{\frac{\pi \sigma^{-1/2}}{8 \sigma_1^2}} \left[ \zeta \sqrt{m} + (\sqrt{m} + \sigma^{-3/2})\mu_{pd} \right] \equiv \pi a. \tag{65}
\]
The variations of $|\gamma|$ with respect to $\sigma$ is shown in Fig. 2 for different values of the mass ratio $m$ [Fig. 2(a)] and the density ratio $\mu_{pd}$ [Fig. 2(b)]. It is seen that the value of $|\gamma|$ slowly decreases with an increase of the temperature ratio $\sigma$ for plasmas with positively charged dusts. However, for plasmas with negatively charged dusts, the value of $|\gamma|$ initially increases until $\sigma$ reaches its critical value, and then decreases with increasing values of $\sigma$. These may be consequences of typical laboratory plasmas (see above) in which positive ion temperature is higher than the negative ions. Also, as the ratio $m (\mu_{pd})$ increases, the value of $|\gamma|$ increases (decreases) [See the solid and dashed lines for positively charged dusts, and the dotted and dash-dotted lines for negatively charged dusts]. Thus, dusty plasmas with a higher concentration of positive ions (and hence of the negative ions in order to maintain the charge neutrality) than the charged dusts reduce the linear Landau damping rate of DAWs. This may be true for some laboratory plasmas as described above. Also, since the mass difference of positive and negative ions can be higher in space plasmas as mentioned above, an enhancement of the damping rate is more likely to occur there. Furthermore, a higher value of $|\gamma|$ for plasmas with negatively charged dusts is seen to occur (Compare the solid and dotted lines or the dotted and dash-dotted lines).

IV. SOLITARY WAVE SOLUTION OF THE KDV EQUATION WITH LANDAU DAMPING

We note that in absence of the Landau damping effect (i.e., $a = 0$), Eq. (59) reduces to the usual KdV equation, the solitary wave solution of which is given by

$$n = N \text{sech}^2 \left( \frac{\xi - U_0 \tau}{W} \right),$$

(66)

where $N = 3U_0/b$ is the amplitude and $W = (12c/Nb)^{1/2}$ is the width and $U_0 = Nb/3$ is the constant phase speed (normalized by $c_s$) of the solitary wave.

To find the solitary wave solution of Eq. (59) with the effect of a small amount of Landau damping, we follow Ref. [20]. Thus, integrating Eq. (59) with respect to $\xi$, one can obtain

$$\frac{\partial}{\partial \tau} \int_{-\infty}^{+\infty} n \, d\xi = 0,$$

(67)

where the equality sign holds only when $n = 0$ for all $\xi$. Equation (68) states that an initial perturbation of the form (69) for which

$$\int_{-\infty}^{+\infty} n^2 \, d\xi < \infty,$$

(69)

will decay to zero. That is, the wave amplitude $N$ is not a constant but decreases slowly with time. In what follows we perform a perturbation analysis of Eq. (59) assuming that $a (\gg \epsilon)$ is a small parameter with $1 \sim b \sim c > a$. The latter may be satisfied for plasmas (e.g., laboratory plasmas in which pair-ions can be $Ar^+SF_6^-$) with $m > 1$ and $\mu_{pd} \sim \sigma \sim 1$. So, we introduce a new space coordinate $z$ in a frame moving with the solitary wave and normalized to its width as

$$z = \left( \xi - \frac{b}{3} \int_0^\tau N d\tau \right) / W,$$

(70)

where $N$ is assumed to vary slowly with time and $N = N(a, \tau)$. Also, assume that $n \equiv n(z, \tau)$. Under this transformation Eq. (59) becomes

$$\frac{\partial n}{\partial \tau} + \frac{a}{W} \int_{-\infty}^{\infty} \frac{\partial n}{\partial z'} \left( z - z' \right) - \left[ \frac{Nb}{3W} - \frac{z}{2N} \left( \frac{dN}{d\tau} \right) \right] \frac{\partial n}{\partial z} + \frac{b}{W} \frac{\partial n}{\partial z} + \frac{c}{W^3} \frac{\partial^3 n}{\partial z^3} = 0,$$

(71)

where we have used $\partial n/\partial z' = \partial n/\partial z$ at $z = z'$.

Next, to investigate the solution of Eq. (71), we follow Ref. [20] and generalize the multiple time scale analysis with respect to $a$. Thus, we consider the solution as

$$n(z, \tau) = n^{(0)}(z) + a n^{(1)}(z) + a^2 n^{(2)}(z) + a^3 n^{(3)}(z) + \cdots,$$

(72)

where $n^{(i)}$, $i = 0, 1, 2, 3, \cdots$, are functions of $\tau = \tau_0, \tau_1, \tau_2, \tau_3, \cdots$ in which $\tau_i$ are given by

$$\tau_i = a^{i} \tau,$$

(73)

where $i = 0, 1, 2, 3, \cdots$. Substituting (72) into Eq. (71), we obtain

$$\left( \frac{\partial n^{(0)}}{\partial \tau} + a \frac{\partial n^{(0)}}{\partial \tau_1} + a^2 \frac{\partial n^{(1)}}{\partial \tau_2} + \cdots \right) + a \left( \frac{\partial n^{(1)}}{\partial \tau} + a \frac{\partial n^{(1)}}{\partial \tau_1} + \cdots \right) + \left[ -\frac{Nb}{3W} - \frac{z}{2N} \left( \frac{dN}{d\tau} \right) + a \frac{\partial n^{(1)}}{\partial \tau_1} + \cdots \right] \times$$

$$\frac{\partial}{\partial z} \left( n^{(0)} + a n^{(1)} + \cdots \right) + \frac{a}{W} \int_{-\infty}^{\infty} \frac{\partial n^{(0)}}{\partial z'} \left( z - z' \right) \frac{\partial n^{(0)}}{\partial z'} + \frac{b}{W} \frac{\partial n^{(0)}}{\partial z} + \frac{c}{W^3} \frac{\partial^3 n^{(0)}}{\partial z^3} + \cdots = 0,$$

(74)

Equating the coefficients of zeroth and first-order of $a$, we successively obtain from Eq. (74) as

$$\beta \left[ \frac{\partial}{\partial \tau} + \frac{z}{2N} \frac{\partial N}{\partial \tau} \right] n^{(0)} + M \frac{\partial n^{(0)}}{\partial z} = 0,$$

(75)
In order that the solution of Eq. (81) exists, it is necessary that $R_{n(0)}$ be orthogonal to all solutions $g(z)$, of $L^+[g] = 0$ which satisfy $g(\pm\infty) = 0$, where $L^+$ is the operator adjoint to $L$, defined by

$$
\int_{-\infty}^{\infty} \psi_1(z)L[\psi_2(z)]dz = \int_{-\infty}^{\infty} \psi_2(z)L^+[\psi_1(z)]dz,
$$

where $\psi_1(\pm\infty) = \psi_2(\pm\infty) = 0$, and the only solution of $L^+[g] = 0$ is $g(z) = \text{sech}^2 z$. Thus, we have

$$
\int_{-\infty}^{\infty} R_{n(0)} \text{sech}^2 zdz = 0,
$$

which gives

$$
\frac{\partial N}{\partial \tau} + \frac{1}{2a} \sqrt{\frac{b}{3c}} N^{3/2} \times \sum \text{sech}^2 z \frac{\partial}{\partial z} \left( \text{sech}^2 z' \right) dzdz' = 0.
$$

Equation (84) is a first-order differential equation for the solitary wave amplitude $N(a, \tau)$, the solution of which is

$$
N(a, \tau) = N_0 \left( 1 + \frac{\tau}{\tau_0} \right)^{-2},
$$

where $N = N_0$ at $\tau = 0$ and $\tau_0$ is given by

$$
\tau_0^{-1} = \frac{a}{4} \sqrt{\frac{bN_0}{3c}} \sum \text{sech}^2 z \frac{\partial}{\partial z} \left( \text{sech}^2 z' \right) dzdz'.
$$

Taking Fourier transform of $\text{sech}^2 z$ and making use of the identity

$$
P \int_{-\infty}^{\infty} \frac{\exp(ikz)}{z - z'} dz = i\pi \text{ sgn } \kappa \exp(ikz'),
$$

one obtains

$$
P \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \text{sech}^2 z \frac{\partial}{\partial z} \left( \text{sech}^2 z' \right) dzdz' = \frac{24}{\pi^2} \zeta(3) = 2.92,
$$

where $\zeta$ is the Riemann zeta function. Thus, from Eq. (86) we have

$$
\tau_0 \approx \frac{1.37}{a} \sqrt{\frac{3c}{bN_0}}.
$$
The final soliton solution of Eq. \([59]\) with the Landau damping is then given by
\[
n = N_0 \left(1 + \frac{\tau}{\tau_0}\right)^{-2} \text{sech}^2 \left[\left(\xi - \frac{b}{3} \int_0^\tau N d\tau\right)/W\right] + O(a).
\]
(90)

This shows that the amplitude of DA solitary waves decays slowly with time with the effect of a small amount of the Landau damping. From Eq. \(90\), it is also seen that as the wave amplitude decreases, the propagation speed also slows down in widening the pulse width.

![Graph](image)

**FIG. 5.** The decay of the solitary wave amplitude [Eq. \(65\)] with time is shown as a result of the Landau damping effect for different values of the parameters \(m\), \(\mu_{pd}\) and \(\sigma\) as relevant for plasmas with positively charged dusts. The other values are taken as \(\alpha_1 = 0.6\), \(\alpha_2 = 0.8\), \(\alpha_3 = 8\) and \(N_0 = 0.2\) so that \(b \sim c \gg a\) is satisfied. The qualitative behaviors remain the same for plasmas with negatively charged dusts.

We numerically investigate the properties of the solitary solutions given by Eqs. \(66\) and \(90\) with different plasma parameters. Figure 3 exhibits the characteristics of the KdV soliton for different values of (a) \(\sigma\) [Fig. 3(a)] and (b) \(\mu_{pd}\) [Fig. 3(b)] for plasmas with positively (PCD) and negatively charged dusts (NCD). The changes of values of the amplitude and width are more pronounced in case of plasmas with negatively charged dusts. In this case, the solitons get widened and their amplitudes remain smaller than the positively charged dust case. From Fig. 3(a) it is seen that as the temperature ratio \(\sigma\) increases, both the amplitude and width of the soliton decrease. On the other hand, as the ratio \(\mu_{pd}\) increases, an increase of the amplitude and a decrease of the width are found to occur [Fig. 3(b)].

Typical forms of the KdV soliton [Fig. 4(a)] and soliton with the effect of Landau damping [Fig. 4(b)] are shown in Fig. 4. The parameter values are for typical laboratory plasmas (as mentioned before) with positively charged dusts. The features are also similar in the case of negatively charged dusts. Clearly, the wave amplitude slows down with time by the effect of a small amount of Landau damping. Such a decay of the wave amplitude with time [Eq. \(55\)] is also exhibited in Fig. 5 for different parameter values. The latter are for plasmas with positively charged dusts with \(m > 1\) and \(\mu_{pd} \sim \sigma \sim 1\). We find that as the mass and temperature ratios increase (Relevant for typical laboratory dusty plasmas mentioned above) there is a slowing down of the wave amplitude. However, such a reduction of the amplitude is more pronounced with a small enhancement of \(\sigma\). Furthermore, an increase of the wave amplitude with the density ratio \(\mu_{pd}\) is also found to occur.

**V. CONCLUSION**

We have investigated the Landau damping effects of both positive and negative ions on small but finite amplitude electrostatic solitary waves in dusty negative-ion plasmas consisting of mobile charged dusts and both positive and negative ions. A Kortweg-de Vries (KdV) equation with a nonlocal integral term (Landau damping) is derived which governs the dynamics of weakly nonlinear and weakly dispersive DAWs. It is found that for typical laboratory \([3, 8, 9]\) and space plasmas \([5]\), the Landau damping (and the nonlinear) effects for both positive and negative ions become dominant over the finite Debye length (dispersive) effects for which the KdV soliton theory is no longer applicable to DAWs in dusty pair-ion plasmas. In such cases and in presence of Landau damping, the soliton amplitude is found to decay with time. The wave amplitude also decreases with an increase of the ratios of negative to positive ion masses \((m)\) and the positive to negative ion temperatures \((\sigma)\). However, the amplitude may be increased with increasing values of the positive ion to dust number density ratio \((\mu_{pd})\). On the other hand, the amplitude and width of the KdV soliton are found to decrease with an increase of \(\sigma\), whereas its amplitude increases and the width decreases with an increase of \(\mu_{pd}\). The results should be useful for understanding the evolution of dust-acoustic solitary waves in dusty negative ion plasmas such as those in laboratory \([3, 8, 9]\) and space environments \([2, 5]\).
