We derive the two-point spectral correlation function of the Dirac operator with a specific external source in the $\epsilon$-regime of QCD. This correlation function has a unique and strong dependence on $F_\pi$, and thus provides an novel way to extract $F_\pi$ from lattice simulations. We test the method in a quenched lattice simulation with staggered fermions.

INTRODUCTION

One of the outstanding challenges to lattice gauge theory is the computation of physical observables that depend strongly on having very small quark masses in QCD. Here we exploit the fact that the low-lying spectrum of the Dirac operator in finite volume is particularly sensitive to the observables of spontaneously broken chiral symmetry. It is well established 1 that the chiral condensate $\Sigma = \langle \bar{\psi} \psi \rangle$ can be extracted from measurements of the low-energy Dirac spectrum. We carry this program one step further to determine the next low-energy constant, the pseudoscalar decay constant $F_\pi$, with similar high precision. We show that a certain spectral correlation function of the Dirac operator depends on $F_\pi$, and thus provides an unique way to extract $F_\pi$ in lattice gauge theory simulations. The method is general for systems with spontaneous symmetry breaking and thus its eigenvalue spectrum lies entirely on the imaginary axis.

Once external currents are included, the leading-order effective Lagrangian of the $\epsilon$-regime depends not only on $\Sigma$, but also on $F_\pi$. We shall introduce an external vector source that can be interpreted either as an imaginary chemical potential for isospin 10 or as twisted boundary conditions for the gauge potentials 14. The advantage of an imaginary isospin chemical potential is twofold. First, the associated Dirac operator has a positive definite determinant and thus becomes amenable to numerical simulations. In addition, with an imaginary isospin potential, the Dirac operator is anti-Hermitian and thus its eigenvalue spectrum lies entirely on the imaginary axis.

For non-zero baryon chemical potential, the $F_\pi$-dependent spectral correlation functions in the $\epsilon$-regime 12, 13, 17 can be used to glean information about chiral symmetry breaking 17. However, the spectrum of the associated Dirac operator is complex, which makes the numerical determination of $F_\pi$ more demanding. Quenched results in that direction have recently been presented 17.

We consider instead the correlation function

$$
\rho(\lambda_1, \lambda_2; i\mu_{\text{iso}}) \equiv \left\langle \sum_n \delta(\lambda_1 - \lambda_n) \sum_m \delta(\lambda_2 - \lambda_m) \right\rangle
$$

between the densities of eigenvalues $i\lambda_n$ of the anti-hermitian operator $D_+$, where

$$
D_+ \psi_n \equiv |\not{D}(A) + i\mu_{\text{iso}}\gamma_0|\psi_n = i\lambda_n \psi_n,
$$

and the eigenvalues $i\tilde{\lambda}_m$ of the likewise anti-hermitian operator $D_-$, defined by

$$
D_- \tilde{\psi}_n \equiv |\not{D}(A) - i\mu_{\text{iso}}\gamma_0|\tilde{\psi}_n = i\tilde{\lambda}_m \tilde{\psi}_n.
$$

Here $\not{D}(A)$ is the Dirac operator associated with the gauge potential $A_\mu$. Considering the operators $D_+$ and...
$D_-$ as acting on two separate flavors leads to a theory in which the $u$-quark has chemical potential $+i\mu_{\text{iso}}$, while the $d$-quark has chemical potential $-i\mu_{\text{iso}}$. Using the effective low energy theory for QCD in the $\epsilon$-regime we will calculate the correlation function (11) in the microscopic limit where both $m\Sigma V$ and $\mu_{\text{iso}}^2F_2^2V$ are held fixed as the four-volume $V$ is taken to infinity. We can measure $\Sigma$ very accurately from the distributions of the smallest eigenvalues of $D_+$. Then the spectral correlation function (14) for eigenvalues of the order $1/(\Sigma V)$ provides, as we shall see, a parameter-free determination of $F_+$ in the chiral limit. Computationally, all that is required is the determination of a modest number (typically, the first 10-20 will suffice) of smallest eigenvalues of the Dirac operators $D_\pm$. As an additional check, one can verify that the dependence is through the combination $\mu_{\text{iso}}^2F_2^2V$ only.

In this paper we will provide formulas and numerical results relevant to quenched QCD. Shortcomings of quenching are well known, and we use this approximation for illustrative purposes only. The case of dynamical quarks will be presented elsewhere.

THE CORRELATION FUNCTION IN THE $\epsilon$-REGIME

The first step is to derive the quenched susceptibility, defined as

$$\chi(m_1, m_2; i\mu_{\text{iso}}) = \lim_{n \to 0} \frac{1}{n^2} \partial_{m_1} \partial_{m_2} \log Z_n(m_1, m_2; i\mu_{\text{iso}})$$

(4)

where the limit $n \to 0$ indicates use of the replica method [18]. In terms of the eigenvalues $\lambda$ and $\lambda$ the susceptibility is

$$\chi(m_1, m_2; i\mu_{\text{iso}}) = \left\langle \sum_n \frac{1}{i\lambda_n + m_1} \sum_m \frac{1}{i\lambda_m + m_2} \right\rangle$$

(5)

$$- \left\langle \sum_n \frac{1}{i\lambda_n + m_1} \right\rangle \left\langle \sum_m \frac{1}{i\lambda_m + m_2} \right\rangle .$$

The spectral correlation function (11) then follows from the discontinuity across the imaginary axis of both $m_1$ and $m_2$,

$$\rho(\lambda_1, \lambda_2; i\mu_{\text{iso}}) = \frac{1}{4\pi^2} \text{Disc} \chi(m_1, m_2; i\mu_{\text{iso}})|_{m_1 = \lambda_1, m_2 = \lambda_2} .$$

(6)

The QCD partition function $Z_n(m_1, m_2; i\mu_{\text{iso}})$ entering Eq. (7) contains $2n$ fermions, half of which have mass $m_1$ and chemical potential $i\mu_{\text{iso}}$, while the other half have mass $m_2$ and chemical potential $-i\mu_{\text{iso}}$. In the $\epsilon$-regime the leading term in the partition function is (11)

$$Z_n(m_1, m_2; i\mu_{\text{iso}}) =$$

(7)

$$\int dU \det(U)^{\nu} e^{\frac{4V}{F_2^2\mu_{\text{iso}}} \text{Tr}[U,B][U^\dagger,B]+\frac{4}{\Sigma} \text{Tr}(M^\dagger U+MU^\dagger)}$$

at fixed gauge field topology $\nu$. The integration is over the Haar measure of $U(2n)$, and we have defined

$$B = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$$

and

$$M = \begin{pmatrix} m_1 & 0 \\ 0 & m_2 \end{pmatrix}.$$
\[
\frac{\chi(m_1, m_2; \mu_{\text{iso}})}{V^4 \Sigma^4} = 4m_1 m_2 \int_0^1 d\lambda \lambda e^{2V F^2 \mu_{\text{iso}}^2} I_\nu(\lambda m_1 \Sigma V)I_\nu(\lambda m_2 \Sigma V) \\
\times \int_1^\infty d\lambda \lambda e^{-2V F^2 \mu_{\text{iso}}^2} K_\nu(\lambda m_1 \Sigma V)K_\nu(\lambda m_2 \Sigma V). 
\]

(14)

Taking the discontinuity as in Eq. (10) we obtain the desired correlation function,

\[
\rho(\xi_1, \xi_2; \mu_{\text{iso}}) = \xi_1 \xi_2 \int_0^1 d\lambda \lambda e^{2V F^2 \mu_{\text{iso}}^2} J_\nu(\lambda \xi_1)J_\nu(\lambda \xi_2) \\
\times \left[ \frac{1}{4V F^2 \mu_{\text{iso}}^2} \exp \left( -\frac{\xi_1^2 + \xi_2^2}{8V F^2 \mu_{\text{iso}}^2} \right) I_\nu \left( \frac{\xi_1 \xi_2}{4V F^2 \mu_{\text{iso}}} \right) \right] - \int_0^1 d\lambda \lambda e^{-2V F^2 \mu_{\text{iso}}^2} J_\nu(\lambda \xi_1)J_\nu(\lambda \xi_2) \right].
\]

(15)

where we have defined the scaling variables \(\xi_1 \equiv \lambda_1 \Sigma V\) and \(\xi_2 \equiv \lambda_2 \Sigma V\). The spectacular change in this correlation function when \(\mu_{\text{iso}}\) is made non-zero can be seen in Fig. 1. A fit to Monte Carlo data with \(\mu_{\text{iso}} \neq 0\) using Eq. (15) will then readily produce a measurement of \(F_x\).

![FIG. 1: The correlation function with one eigenvalue fixed at \(\xi_2 = 4\), for \(F_x\mu_{\text{iso}}\sqrt{\nu} = 0.0717\) (full) and for \(\mu_{\text{iso}} = 0\) (dashed). The \(\delta\)-function peak at \(\xi_1 = \xi_2\) for \(\mu_{\text{iso}} = 0\) has not been shown.](image)

The pronounced effect of \(\mu_{\text{iso}} \neq 0\) in the region where \(\lambda\) is close to \(\bar{\lambda}\) is not difficult to explain. For \(\mu_{\text{iso}} = 0\) both \(\lambda\) and \(\bar{\lambda}\) are eigenvalues of \(D\), and this leads to a \(\delta\)-function contribution to the correlation function stemming from the non-compact integral in the bosonic partition function (14), which diverges for \(\mu_{\text{iso}} = 0\) at \(\lambda_1 = \bar{\lambda}_2\). In this way we recover from Eq. (15) the known result (22).

\[
\rho(\xi_1, \xi_2; \mu_{\text{iso}} = 0) = \delta(\xi_1 - \xi_2) \left( \frac{1}{2} [J^{\prime}_\nu(\xi_1) - J_{\nu+1}(\xi_1)J_{\nu-1}(\xi_1)] \right)
\]

(16)

\[-\frac{\xi_1 \xi_2}{(\xi_1^2 - \xi_2^2)^2} \left( J_{\nu+1}(\xi_1)J_{\nu+1}(\xi_2) - J_{\nu+1}(\xi_2)J_{\nu+1}(\xi_1) \right) \]

The \(\delta\)-function is not shown in the \(\mu_{\text{iso}} = 0\) curve in Fig. 1. When \(\mu_{\text{iso}}\) is non-zero, \(\lambda\) is an eigenvalue of \(D_+\) while \(\bar{\lambda}\) is an eigenvalue of \(D_-\); the effect of \(\mu_{\text{iso}}\) is therefore to smooth out the \(\delta\)-function into a pronounced peak for \(\lambda\) near \(\bar{\lambda}\).

**NUMERICAL SIMULATIONS**

To test the method, we have performed simulations of quenched QCD using staggered fermions for \(V = 8^4\) (\(\mu_{\text{iso}} = 0.01\)) and \(V = 12^4\) (\(\mu_{\text{iso}} = 0.002\)). We have chosen to work with the standard Wilson plaquette action at \(\beta = 5.7\) and with conventional, unimproved Dirac operators. In this way we are sure to have no ambiguities in the identification of the coset space of spontaneous chiral symmetry breaking, which here is \(U(2n)\). The analysis presented above is based on the coset space \(SU(2n)\). We can account for the extra \(U(1)\) factor here by setting \(\nu = 0\) in the formulas and comparing to numerical results without fixed topology (see for example the first paper of ref. 4). Simulation at weaker coupling or the use of improved actions and Dirac operators will induce a crossover from \(\nu = 0\) behavior to an explicit dependence on topological index (25), but it is not our purpose to explore that aspect here.

We include a chemical potential on the lattice in the standard way (24). For an imaginary chemical potential this amounts to including a constant abelian gauge field with non-vanishing timelike component \(\mu\) only. It leaves the hermiticity properties of the Dirac operator unchanged, allowing the computation of the lowest-lying eigenvalues with the Ritz variational algorithm (24).

When extracting physical observables we must keep in mind that the continuum theory describes 4 tastes of quark. In our simulation the staggered Dirac matrix is 4 times larger than that of a single continuum quark. The
statistical properties of the eigenvalue spectrum of that matrix behave as in a theory of one species in a volume four times as big. Therefore, to determine the values of $F_\pi$ and $\Sigma$ from the staggered eigenvalue spectrum we replace $V$ in the analytical predictions by $4V$.

First we measure $\Sigma$. We can do that by fitting individual eigenvalue distributions to the analytical expressions \[ \langle \rho(\xi) \rangle = \frac{1}{\sqrt{V}} \int_{\xi_{\min}}^{\xi_{\max}} d\xi \rho(x; i\mu_u) \] using the best fit to the analytical result $\langle \rho(x; i\mu_u) \rangle = 1/V$. This follows from Eq. (7) by taking $B$ proportional to the unit matrix, and it ensures in particular that individual eigenvalue distributions are $\mu_{\text{iso}}$-independent in this limit \[ \langle \rho(\xi) \rangle = 0 \] (dashed). Alternatively, one can use the 2-point correlation functions of either $D_+$ or $D_-$. As follows from the argument above, these 2-point functions are $\mu_{\text{iso}}$-independent, and they can provide independent determinations of $\Sigma$ \[ \Sigma = 0 \] (dashed).

Using the latter approach for our $12^4$ data, a best fit gives us in lattice units the bare value $\Sigma = 0.0634(3)$ with $\chi^2/\text{dof} = 0.55$. This value is consistent with what we find by fitting either individual eigenvalue distributions or the overall flat eigenvalue plateau. We can then determine $F_\pi$ by a fit of the measured correlation function $\langle \rho(\xi) \rangle$ to the analytical result $\langle \rho(x; i\mu_u) \rangle = 1/V$. In Fig. 2 we show the data for $V = 8^4$ and compare them to the analytical curves using the best fit to $F_\pi$ from the $12^4$ data, as explained below. On $V = 8^4$ with $\beta = 5.7$ only the first few eigenvalues have distributions in agreement with the predictions of the $\epsilon$-regime. For this reason we base our measured values of $\Sigma$ and $F_\pi$ on our $12^4$ lattice simulations.

Requiring that the eigenvalue $\tilde{\epsilon}_1$ fall within one bin around a fixed value (here $\tilde{\epsilon}_2 = 4$) means that a large fraction of the lattice configurations is obviously not used. In order to improve the statistics we consider the integrated correlation function

\[ \rho_{\text{int}}(x; i\mu_u) \equiv \int_{\xi_{\min}}^{\xi_{\max}} d\xi \rho(x + \xi; i\mu_u). \]  

In Fig. 3 we show this integrated correlation function as measured on our $12^4$ ensemble.

The best fit gives us $F_\pi = 0.1245(18)$ in bare lattice units with a $\chi^2/\text{dof} = 0.33$. This value is consistent with the result $F_\pi = 0.118(7)$ of ref. \[27\], which uses the same action and gauge coupling $\beta = 5.7$ (but of course a different method for extracting $F_\pi$).

It is well known that the unimproved staggered action leads to serious scaling violations. To quote a result in physical units would, at this value of $\beta$, require the use of improvement methods to reduce lattice artifacts. This is beyond the scope of this paper.

![FIG. 2: The correlation function with fixed $\tilde{\epsilon}_2 = 4$ measured on our $8^4$ lattice. The curves correspond to $\langle \rho(\xi) \rangle$ with $F_\pi \mu_{\text{iso}} \sqrt{V} = 0.159$ (full) and $\mu_{\text{iso}} = 0$ (dashed).](image)

![FIG. 3: The integrated correlation function $\rho_{\text{int}}(x; i\mu_u)$ with $\xi_{\min} = 4$ and $\xi_{\max} = 43$. The value $F_\pi \mu_{\text{iso}} \sqrt{V} = 0.0717$ is the best fit.](image)

**SUMMARY**

We have proposed and tested a new method to measure $F_\pi$ in lattice gauge theory simulations, using the pronounced $F_\pi$-dependence of a specific 2-point correlation function of the Dirac operator in the $\epsilon$-regime.

We have performed quenched lattice simulations that demonstrate excellent agreement with our analytical predictions. Our study illustrates the ease with which this method can be implemented, and the high precision that can be achieved.
