Abstract

AIM: To investigate the indications and outcomes of liver transplantation for hepatic epithelioid hemangioendothelioma (HEHE).

METHODS: Between 1989 and August 2013, in the Department of General, Transplant, and Liver Surgery, Medical University of Warsaw, 1306 orthotopic liver transplantsations (OLTx) were performed, including 72 retransplantations. Unresectable HEHE was an indication for OLTx in 10 patients (0.8% of primary OLTx), the mean age of the patients was 40.5 ± 13.3 years (range 23-65 years), and the male-to-female ratio was 2:8. Kaplan-Meier survival analysis in HEHE, hepatocellular carcinoma (HCC), and other OLTx recipients groups was performed. The differences in mortality were compared using the χ² test. A P-value < 0.05 indicated statistical significance.

RESULTS: No concomitant liver disease was found in any patient. There was no neoadjuvant chemotherapy or radiotherapy. Liver function test results were normal in most of the patients. The levels of alpha-fetoprotein, carcinoembryonic antigen, and carbohydrate antigen 19-9 were normal. In immunohistochemical staining, the neoplastic cells were positive for factor VIII-related antigen, CD31, and CD34, which are endothelial cell markers, and negative for cytokeratin 19, cytokeratin 7, and HepPar-1. Nine patients were alive without tumor recurrence. One patient died 2 mo after OLTx due to septic complications. No morbidity was observed. Maximum follow-up was 11.4 years, with a minimum of 1 mo. The cumulative survival rate at the end of follow-up in HEHE patients was 87.5% compared with 54.3% in the HCC group and 76.3% in the other OLTx recipients group (χ² test = 1.784, d.f. = 2, P = 0.409).

CONCLUSION: Unresectable HEHE, without extrahepatic metastases is an excellent indication for liver transplantation. Long-term survival is very good and much better than in HCC patients and the entire group of OLTx patients.

Key words: Hemangioendothelioma; Liver transplantation; Liver malignancies; Transplantation results; Transplantation indications

Core tip: Epithelioid hemangioendothelioma (EHE) of the liver (hepatic EHE, HEHE) is a very rare tumor of mesenchymal origin. It typically occurs in female patients aged 20-40 years. HEHE is resistant to chemotherapy. Unresectable tumor, limited to the liver, may be a good indication for liver transplantation. The aim of this paper was to analyze the indications and outcomes of liver transplantation for HEHE.

INTRODUCTION

Hemangioendothelioma (epithelioid hemangioendothelioma, EHE) is a rare tumor of endothelial and connective tissue origin, resembling hemangioma. This type of tumor was first described by Weiss and Enzinger[1]. Its incidence does not exceed 1 case per million[2]. EHEs are found in soft tissue and internal organs. The most commonly affected organ is the liver (hepatic EHE, HEHE). Other localizations such as the lungs, peritoneum, spleen, bones, brain, meninges, breast, heart, head, and stomach have been described in the literature[3-7].

The mechanisms underlying the development of HEHE are not known. Possible risk factors include oral contraception, toxicity associated with vinyl chloride or asbestos exposure, excessive alcohol consumption, liver injuries, viral hepatitis, and other chronic liver diseases[8].

Numerous recent studies also suggest genetic mechanisms underlying the development of EHE. Specific chromosomal translocation t(1;3)(p36.3;q25) is typical for this type of tumor[9-11].

HEHE is typically diagnosed in young females aged 20-40 years. The prognosis without treatment is poor. Most patients present with disseminated disease, which usually involves both lobes of the liver. Currently there are several methods of treatment available, including surgery (liver resection and transplantation), chemotherapy, transarterial chemoembolization (TACE), radiotherapy, and radiofrequency ablation (RFA). Multifocal unresectable HEHE may be an indication for OLTx[12].

The aim of this study was to assess the outcomes of OLTx in patients with HEHE.

MATERIALS AND METHODS

Between 1989 and August 2013, 1306 orthotopic liver transplantations (OLTx) in adults including 72 re-transplantations (re-OLTx) were performed in the Department of General, Transplant, and Liver Surgery, Medical University of Warsaw. Unresectable HEHE was an indication for OLTx in 10 patients. The mean age of patients was 40.5 ± 13.3 years (range 23-65 years), and the male-to-female was ratio 2:8.

Statistical analysis

We compared Kaplan-Meier distributions of the time to death between HEHE and hepatocellular carcinoma (HCC) groups and with the general liver transplant population, using the χ² test. The differences were considered statistically significant when the P-value was < 0.05.

RESULTS

The initial referral diagnosis was usually different from the final diagnosis of HEHE. Most commonly the lesions were described as hemangioma, metastases of unknown origin, or parasitic abscesses. In our Department, the diagnosis was based on a wedge liver biopsy obtained during diagnostic laparoscopy. In 2 patients the diagnosis was based on radiologic assessment of the lesions in the liver (computed tomography or magnetic resonance imaging). No patient had neoadjuvant chemotherapy or radiotherapy. Liver function test results were normal in most of the patients. In 4 more advanced cases mild elevation of markers of cholestasis such as alkaline phosphatase (ALP) and gamma-glutamyl transpeptidase (GGTP) was observed. In all the patients with HEHE, the levels of alpha-fetoprotein (AFP), carcinoembryonic antigen (CEA), and carbohydrate antigen 19-9 (CA19-9) were normal (Table 1).

No concomitant liver disease was found in any patients. The symptoms were usually nonspecific, with mild epigastric or right upper quadrant pain or discomfort. Sometimes fatigue or weight loss was reported (Table 2). The severity of the disease symptoms increase as the disease progressed, with increasing numbers and size of the lesions.

Macroscopically, cross-sections of the resected liver showed multifocal non-encapsulated, yellowish-white tumors that involved both lobes, ranging in diameter from 0.2 to 18 cm. Subcapsular tumors showed typical umbilication.

Microscopically, the tumors had a high cellular growth pattern with infiltrative margins. Histopathological examination demonstrated a variable cellularity - the cellular components were dominant in the peripheral region, while central areas of the nodules showed both necrosis and sclerosis and some were calcified. In the more cellular areas, tumor cells were arranged in solid cords and nests, mimicking epithelioid or histiocytoid cells. In other, less cellular, areas having a sclerotic matrix, single neoplastic cells had irregular cytoplasmic processes. Epithelioid cells were round in shape and had an eosinophilic abundant cytoplasm and vesicular nuclei. Dendritic cells displayed spindle morphology with interdigitating processes. Characteristically, tumors consisted of spindle-shaped cells and signet ring cell-like structures with intracytoplasmic lumina that contained erythrocytes. Architectural features, such as an intravascular or intrasinusoidal growth pattern characteristic of a neoplasm were observed. Microvascular invasion was found in 2 cases. The parenchymal architecture of the liver was preserved. Immunohistochemical staining, the neoplastic cells were positive for factor VIII-related antigen, endothelial cell markers CD31 and CD34, and negative for cytokeratin 19, cytokeratin 7, and HepPar-1 (Figure 1 and Table 3).

The follow-up for the HEHE group ranged from 1 mo to 11.4 years. There was no tumor-related mortality.
One patient died 2 mo after OLTx due to septic complications not related to the nature of the HEHE. When this case of tumor-unrelated death was excluded from the analysis, the long-term survival in HEHE patients was 100%. No morbidity was observed. The remaining 9 patients are alive without any tumor recurrence symptoms.

Among all patients after OLTx ($n = 1234$), 3 groups were defined for the purpose of survival analysis: patients with HEHE ($n = 10$); patients with HCC ($n = 155$), which is the most common tumor considered an indication for OLTx; and the remaining group of OLTx recipients ($n = 1069$).

Kaplan-Meier analysis showed a 3-year cumulative survival rate of 87.5% for the HEHE group, 80.1% for

Figure 2  Kaplan-Meier survival analysis. Kaplan-Meier survival analysis in the hepatic epithelioid hemangioendothelioma (HEHE), hepatocellular carcinoma (HCC), and other orthotopic liver transplantations recipients groups.

The cumulative survival rate at the end of the follow-up was 87.5% in the HEHE patients, compared with 54.3% in the HCC group and 76.3% in the other OLTx recipients group ($\chi^2$ test = 1.784, df = 2, $P = 0.409$) (Figure 2).

DISCUSSION

EHE is a very rare tumor. The low incidence precludes any randomized clinical study for the assessment of the best means of treatment. The available publications usually present a retrospective assessment of a single center experience and most of the papers are single case reports. The prognosis depends on the organ involved and, for a hepatic localization, the overall outcome is poor. The disease follows an unpredictable course, which is another confounding factor in the development of a treatment strategy. Disease progression may vary widely from mild with long-term survival[19,20] to severe with rapid deterioration[15,16]. Cases of spontaneous complete remission of HEHE have also been published[17]. There are no reliable predictive factors allowing for the assessment of prognosis. Well known tumor-related factors such as mitotic index, allowing for prediction of malignant potential, did not show any predictive value in cases of HEHE and are considered of low value in clinical practice.

In most of the cases, the disease is asymptomatic or the symptoms are only mild. The most commonly reported symptoms include abdominal pain or right subcostal discomfort related to hepatomegaly. Generalized cachexia or jaundice is less commonly present[18]. Similar symptoms were also observed in the current study patients. Most of the patients presented with normal blood tests. There were increased ALP and GGTP levels present in some cases but the levels of tumor markers such as CEA, CA19-9, and AFP were normal. These results are typical for HEHE[19].

All the studied HEHE tumors had typical pathology and immunohistochemical pattern with positive factor VII staining and positive endothelial markers CD31 (platelet endothelial cell adhesion molecular 1) and CD34 (human hematopoietic progenitor cell antigen)[20,21].

In 2006, Mehrabi et al.[22] published a meta-analysis of studies published between 1984 and 2005 that included 402 cases of HEHE. Treatment details and outcomes were available for 286 cases. It was the largest meta-analysis of HEHE studies. At the time of diagnosis, most patients presented with symptoms of the disease, including, most commonly, right epigastric pain, hepatomegaly, and weight loss. Most of the patients had a multifocal involvement of both lobes of the liver. Extrahepatic disease was present in 36.6% of the patients. The most commonly encountered extrahepatic localizations were the lungs (8.5%), lymph nodes (7.7%), peritoneum (6.1%), bones (4.9%), spleen (3.2%), and diaphragm (1.6%). The most common method of treatment according to the meta-analysis was OLTx (44.8% of cases). Limited extrahepatic focal lesions were not considered an absolute contraindication to OLTx. The outcomes of OLTx are shown in Table 3. In the meta-analysis, 1-year disease-free survival was 81.3% (Table 4). The disease recurrence rate was 27% regardless of the treatment method used. Most of the HEHE liver recurrence was observed more than 2 years after transplantation. There was no recurrence in the study group. In the meta-analysis of Mehrabi et al.[23], 21% of patients received radiotherapy or systemic chemotherapy or TACE. There is no consensus on pref-
considered an option, if possible. In patients with bilobar evidence of extrahepatic disease. Liver resection should be by the assessment of surgical resectability and the pres. Histopathological confirmation of the tumor is followed its clinical significance. Moreover, in most of the radiotherapy cases, this method was used in combination with chemotherapy. In patients receiving chemotherapy or radiotherapy, 5-year survival was 30%. Liver resection was performed in 9.4% of the patients in the meta-analysis of Mehrabi et al[22]. Radical liver resection might be a treatment of choice, but usually the disease is locally advanced at the time of diagnosis and the patients do not qualify for surgery. Palliative resection is not recommended for this type of tumor due to a high risk of progression and recurrence after surgery[23]. The prognosis after liver resection is independent of the presence of extrahepatic lesions; therefore, extraha
erable treatment, no criteria for introducing specific medications into a treatment plan, and no prospective studies evaluating their efficacy. In non-randomized observational studies, several drugs such as thalidomide, doxorubicin, 5-fluorouracil, and vincristine led to a reduction in lesion size or improvement in general status. TACE seems to be an acceptable bridge treatment in patients awaiting liver transplantation, similar to patients with HCC. There are single reports of successful use of interferon alpha 2b in the treatment of extraha
erable treatment, no criteria for introducing specific medications into a treatment plan, and no prospective studies evaluating their efficacy. In non-randomized observational studies, several drugs such as thalidomide, doxorubicin, 5-fluorouracil, and vincristine led to a reduction in lesion size or improvement in general status. TACE seems to be an acceptable bridge treatment in patients awaiting liver transplantation, similar to patients with HCC. OLTx: Orthotopic liver transplantations; TACE: Transarterial chemoembolization; UNOS: United Network for Organ Sharing; ELTR: European Liver Transplant Registry.

Intrahepatic tumor spread without an involvement of other viscera, liver transplantation is the treatment of choice. Adjuvant chemotherapy, neoadjuvant TACE, chemoradiotherapy, and radiotherapy are all available treatment options for cases of extraha
erable treatment, no criteria for introducing specific medications into a treatment plan, and no prospective studies evaluating their efficacy. In non-randomized observational studies, several drugs such as thalidomide, doxorubicin, 5-fluorouracil, and vincristine led to a reduction in lesion size or improvement in general status. TACE seems to be an acceptable bridge treatment in patients awaiting liver transplantation, similar to patients with HCC. There are single reports of successful use of interferon alpha 2b in the treatment of extraha
erable treatment, no criteria for introducing specific medications into a treatment plan, and no prospective studies evaluating their efficacy. tients with symptoms \((n = 17; \ p = 0.001, \text{hazard ratio} = 86.5)\) (12 with abdominal pain or discomfort, 3 with chest pain, 1 with weight loss, and 1 with jaundice) had poorer overall survival. The presence of symptoms was validated as the only significant independent prognostic factor \((P = 0.012)\) by multivariate analysis\(^{[20]}\).

Grotz et al\(^{[27]}\) presented outcomes of 30 patients with HEHE who received treatment at the Mayo Clinic between 1984 and 2007. Liver resection was performed in 11 patients, OLTx in 11 patients, chemotherapy in 5 patients, and the remaining 3 patients received no intervention. The survival rates were similar to the studies reported previously (Table 4). The authors suggested that liver resection may be a suitable solution in patients with a solitary lesion limited to the liver, and OLTx may be offered to patients with multiple lesions in the liver \((> 10\text{ lesions and involvement of } > 4\text{ segments})\). Both methods resulted in comparable outcomes regarding survival and recurrence rate. According to the authors from the Mayo Clinic, the extrahepatic lesions (present in 37\% of the patients) should not be considered a contraindication to surgery, because they did not influence the outcomes in the study group. Chemotherapy was not effective in this group of patients. Grotz et al\(^{[27]}\) presented a treatment protocol based on selected risk factors. The authors focused on the type of intrahepatic dissemination of the tumor, the number of segments involved, the number and size of the lesions, and the presence of extrahepatic disease. Liver resection or RFA of the tumors was suggested in cases with a maximum of 10 lesions measuring not more than 10 cm in diameter and involving not more than 4 segments of the liver. In the other cases, OLTx was recommended. Extrahepatic lesions were not considered a contraindication to any form of surgical intervention, but chemotherapy and metastasectomy were strongly suggested. The authors also recommended liver resection or RFA in the case of local recurrence in the liver\(^{[27]}\).

Nudo et al\(^{[25]}\), in a Canadian multicenter study, presented treatment outcomes of 11 patients. Four patients received adjuvant therapy for HEHE before OLTx [interferon therapy \((n = 1)\), splenectomy \((n = 1)\), adriamycin therapy \((n = 1)\), and surgical resection \((n = 1)\)]. There was a 36.4\% recurrence rate of HEHE during follow-up (on average, 25 mo from OLTx). Two patients with local recurrence underwent liver resection. In the 2 remaining cases of recurrence, radiotherapy or pegylated interferon was administered\(^{[29]}\).

Cardinal et al\(^{[29]}\) analyzed results of 25 patients who received treatment during 1976-2007 and found that the mean survival time was longer in the OLTx group (172 mo) compared with the TACE group (83 mo), but this difference did not reach statistical significance.

Liver resection should be considered the treatment of choice in patients with resectable HEHE. However, a substantial group of patients present with locally advanced disease that is initially unresectable. The results of the present study show that OLTx is a valid and effective method of treatment in patients with unresectable HEHE. The survival rates of patients after OLTx for HEHE were superior to survival rates of patients with HCC who underwent OLTx. Moreover, the survival of HEHE patients was better than the survival of patients with OLTx for other indications. The small number of patients in the HEHE group compared with the other groups of patients has to be considered, since it may lead to a significant statistical bias. The outcomes presented in the current study are comparable to the best outcomes published in the literature. The authors of the current study suggest following a reasonable qualification protocol that enables selection of an appropriate treatment for a specific patient. In the study group, all of the patients presented with the disease limited to the liver, which might positively influence the outcomes, but most of the authors do not consider extrahepatic lesions a contraindication to OLTx. The use of multiple methods of treatment may result in some benefits for survival related to the presumed synergistic effect of combined surgery and chemotherapy, radiotherapy, or TACE. Further studies are necessary to refine treatment protocols in HEHE, but it may be impossible to produce good quality evidence due to the very low incidence of the tumor.

## COMMENTS

### Background

Epithelioid hemangioendotheloma (EHE) is a rare tumor of endothelial and connective tissue origin. EHEs are found in soft tissue and internal organs. The most commonly affected organ is the liver. Hepatic EHE (HEHE) is typically diagnosed in young females aged 20-40 years. Most patients present with disseminated disease, which usually involves both lobes of the liver. The treatment options include surgery (liver resection and transplantation), chemotherapy, transarterial chemoembolization (TACE), radiotherapy, and radiofrequency ablation. Multifocal unresectable HEHE may be an indication for orthotopic liver transplantation (OLTx).

### Research frontiers

Adequate selection for OLTx is of utmost importance among patients with liver tumors. The comparison of outcomes in OLTx for HEHE with outcomes in patients with other tumors, especially hepatocellular carcinoma, provides a good basis for decision-making in this type of indication for transplantation.

### Applications

The results of the present study show that OLTx is a valid and effective method of treatment in patients with unresectable HEHE. A reasonable qualification protocol that enables selection of an appropriate treatment for a specific patient is needed. The use of multiple methods of treatment may result in some benefits for survival related to the presumed synergistic effect of combined surgery and chemotherapy, radiotherapy, or TACE. Further studies are necessary to refine treatment protocols in HEHE but it may be impossible to produce good quality evidence due to the very low incidence of the tumor.

### Peer review

The authors described a series of 10 HEHE cases that were candidates for liver transplantation. As reported by the authors, the outcome was very good compared to HCC and other liver diseases as a whole. In general, the article is interesting and represent the experience of a single center, adding a new experience to other published reports, which were well-discussed by the authors.
