ON POSITIVITY OF KAUFFMAN BRACKET SKEIN ALGEBRAS OF SURFACES

THANG T. Q. LÊ

ABSTRACT. We show that the Chebyshev polynomials form a basic block of any positive basis of the Kauffman bracket skein algebras of surfaces.

1. Introduction

1.1. Positivity of Kauffman bracket skein algebras. Let \( \mathbb{Z}[q^{\pm 1}] \) be the ring of Laurent polynomial in an indeterminate \( q \) with integer coefficients. Suppose \( \Sigma \) is an oriented surface. The Kauffman bracket skein algebra \( S_{\mathbb{Z}[q^{\pm 1}]}(\Sigma) \) is a \( \mathbb{Z}[q^{\pm 1}] \)-algebra generated by unoriented framed links in \( \Sigma \times [0,1] \) subject the Kauffman skein relations \( [\text{Kau}] \) which are recalled in Section 2. The skein algebras were introduced by Przyticki [Pr] and independently Turaev [Tu] in an attempt to generalize the Jones polynomial to links in general 3-manifolds, and have connections and applications to many interesting objects like character varieties, topological quantum field theories, quantum invariants, quantum Teichmüller spaces, and many others, see e.g. [BW, Bu, PS, LT, Mu, Pr, Th].

The quotient \( S_{\mathbb{Z}}(\Sigma) = S_{\mathbb{Z}[q^{\pm 1}]}(\Sigma)/(q-1) \), which is a \( \mathbb{Z} \)-algebra, is called the skein algebra at \( q = 1 \).

For \( R = \mathbb{Z} \) let \( R_+ = \mathbb{N} \), the set of non-negative integers, and for \( R = \mathbb{Z}[q^{\pm 1}] \) let \( R_+ = \mathbb{N}[q^{\pm 1}] \), the set of Laurent polynomials with non-negative coefficients, i.e. the set of \( \mathbb{N} \)-linear combinations of integer powers of \( q \). An \( R \)-algebra, where \( R = \mathbb{Z}[q^{\pm 1}] \) or \( R = \mathbb{Z} \), is said to be positive if it is free as an \( R \)-module and has a basis \( B \) in which the structure constants are in \( R_+ \), i.e. for any \( b, b', b'' \in B \), the \( b \)-coefficient of the product \( b'b'' \) is in \( R_+ \). Such a basis \( B \) is called a positive basis of the algebra.

The important positivity conjecture of Fock and Goncharov [FoG] states that \( S_R(\Sigma) \) is positive for the case \( R = \mathbb{Z}[q^{\pm 1}] \) and \( R = \mathbb{Z} \). The first case obviously implies the second. The second case, on the positivity over \( \mathbb{Z} \), was proved by D. Thurston [Th]. Moreover, D. Thurston make precise the positivity conjecture by specifying the positive basis as follows.

A normalized sequence of polynomials over \( R \) is a sequence \( P = (P_n(t))_{n \geq 0} \) of polynomials in \( R[t] \) is a monic polynomial of degree \( n \). Every normalized sequence \( P \) over \( R \) gives rise in a canonical way to a basis \( B_P \) of the \( R \)-module \( S_R(\Sigma) \), see Section 2.

Definition 1. A sequence \( P = (P_n(t))_{n \geq 0} \) of polynomials in \( R[t] \) is positive over \( R \) if it is normalized and the basis \( B_P \) is a positive basis of \( S_R(\Sigma) \), for any oriented surface \( \Sigma \).

Then D. Thurston proved the following.

Theorem 1.1 (Th). The sequence \( (T_n) \) of Chebyshev’s polynomials is positive over \( R = \mathbb{Z} \).

Supported in part by National Science Foundation.
2010 Mathematics Classification: Primary 57N10. Secondary 57M25.
Key words and phrases: Kauffman bracket skein module, positive basis.
Here in this paper, Chebyshev’s polynomials \( T_n(t) \) are defined recursively by
\[
T_0(t) = 1, \quad T_1(t) = t, \quad T_2(t) = t^2 - 2, \quad T_n(t) = tT_{n-1}(t) - T_{n-2}(t) \quad \text{for} \quad n \geq 3.
\]
If \( T_0 \) is the constant polynomial 2, then the above polynomials are Chebyshev’s polynomials of type 1. Here we have to set \( T_0 = 1 \) since by default, all normalized sequence begins with 1.

D. Thurston suggested the following conjecture, making precise the positivity conjecture.

**Conjecture 1.** The sequence \((T_n)\) of Chebyshev’s polynomials is positive over \( \mathbb{Z}[q^{\pm 1}] \).

We will show

**Theorem 1.2.** Let \( R = \mathbb{Z} \) or \( R = \mathbb{Z}[q^{\pm 1}] \) and \( P = (P_n(t))_{n \geq 0} \) be a sequence of polynomials in \( R[t] \). If \( P \) is positive over \( R \), then \( P_n(t) \) is an \( R_+ \)-linear combination of \( T_0(t), T_1(t), \ldots, T_n(t) \). Besides, \( P_1(t) = T_1(t) = t \).

For the case \( R = \mathbb{Z} \), this result complements well Theorem 1.1 above, as they together claim that the sequence of Chebyshev polynomials is the minimal one in the set of positive sequence over \( \mathbb{Z} \). For \( R = \mathbb{Z}[q^{\pm 1}] \), our result says that the sequence of Chebyshev polynomial should be the minimal positive sequence. A stronger version of Theorem 1.2 is proved in Section 3.

**Remark 1.1.** The positivity conjecture considered here is different from the one discussed in [MSW], which claims that every element of a certain basis is a \( \mathbb{Z}_+ \)-linear combination of monomials of cluster variables.

### 1.2. Marked surfaces

A marked surface is a pair \((\Sigma, P)\), where \( \Sigma \) is a compact oriented surface with (possibly empty) boundary \( \partial \Sigma \) and \( P \) is a finite set in \( \partial \Sigma \). G. Muller [M] defined the skein algebra \( \mathcal{A}_R(\Sigma, P) \), extending the definition from surfaces to marked surfaces. When \( R = \mathbb{Z} \), this algebra had been known earlier, and actually, the above mentioned result of D. Thurston (Theorem 1.1) was proved also for the case of marked surfaces. However, there are two types of basis generators of the skein algebras, namely loops and arcs, and one needs two normalized sequences of polynomials \( P \) and \( Q \) to define an \( R \)-basis of the skein algebra \( \mathcal{A}_R(\Sigma, P) \). Here \( P \) is applicable to loops, and \( Q \) is applicable to arcs, see Section 4. A pair of sequences of polynomials \((P, Q)\) are positive over \( R \) if they are normalized and the basis they generate is positive for any marked surface. D. Thurston result says that with \( P = (T_n) \) , the sequence of Chebyshev polynomials, and \( Q = (Q_n) \) defined by \( Q_n(t) = t^n \), the pair \((P, Q)\) are positive over \( \mathbb{Z} \). We obtained also an extension of Theorem 1.2 to the case of marked surface as follows.

**Theorem 1.3.** Let \( R = \mathbb{Z} \) or \( R = \mathbb{Z}[q^{\pm 1}] \). Suppose a pair \((P, Q)\) of sequences of polynomials in \( R[t] \), \( P = (P_n(t))_{n \geq 0} \) and \( Q = (Q_n(t))_{n \geq 0} \), are positive over \( R \). Then \( P_n(t) \) is an \( R_+ \)-linear combination of \( T_0(t), T_1(t), \ldots, T_n(t) \) and \( Q_n(t) \) is an \( R_+ \)-linear combination of \( 1, t, \ldots, t^n \). Moreover, \( P_1(t) = Q_1(t) = t \).

### 1.3. Acknowledgment

The author would like to thank D. Thurston for valuable discussions. The author also thanks the anonymous referees for useful comments which in particular lead to the current, stronger formulation of Theorem 1.2. This work is supported in part by the NSF.

### 1.4. Plan of the paper

In Section 2 we recall basic facts about the Kauffman bracket skein algebras of surfaces. We present the proofs of Theorem 1.2 and Theorem 1.3 in respectively Section 3 and Section 4.

2. Skein algebras

We recall here basic notions concerning the Kauffman bracket skein algebra of a surface.
2.1. **Ground ring.** Throughout the paper we work with a ground ring $R$ which is more general than $\mathbb{Z}$ and $\mathbb{Z}[q^{\pm 1}]$. We will assume that $R$ is a commutative domain over $\mathbb{Z}$ containing an invertible element $q$ and a subset $R_+$ such that

- $R_+$ is closed under addition and multiplication
- $q, q^{-1} \in R_+$, and
- $R_+ \cap (-R_+) = \{0\}$.

For example, we can take $R = \mathbb{Z}$ with $q = 1$ and $R_+ = \mathbb{Z}_+$, or $R = \mathbb{Z}[q^{\pm 1}]$ with $R_+ = \mathbb{Z}_+[q^{\pm 1}]$. The reader might think of $R$ as one of these two rings.

2.2. **Kauffman bracket skein algebra.** Suppose $\Sigma$ is an oriented surface. The *Kauffman bracket skein module* $\mathcal{S}_R(\Sigma)$ is the $R$-module freely spanned by isotopy classes of non-oriented framed links in $\Sigma \times [0, 1]$ modulo the *skein relation* and the *trivial loop relation* described in Figure 1. In all

\[
\begin{align*}
q & = \quad q^{-1} & -q^2 - q^{-2}
\end{align*}
\]

*Figure 1.* Skein relation (left) and trivial loop relation

Figures, framed links are drawn with blackboard framing. More precisely, the trivial loop relation says if $L$ is a loop bounding a disk in $\Sigma \times [0, 1]$ with framing perpendicular to the disk, then $L = -q^2 - q^{-2}$. And the skein relation says

\[
L = qL_+ + q^{-1}L_-
\]

if $L, L_+, L_-$ are identical except in a ball in which they look like in Figure 2

\[
\begin{align*}
\text{From left to right: } & L, L_+, L_-.
\end{align*}
\]

For future reference, we say that the diagram $L_+$ (resp. $L_-$) in Figure 2 is obtained from $L$ by the positive (resp. negative) resolution of the crossing.

The $R$-module $\mathcal{S}_R(\Sigma)$ has an algebra structure where the product of two links $\alpha_1$ and $\alpha_2$ is the result of stacking $\alpha_1$ atop $\alpha_2$ using the cylinder structure of $\Sigma \times [0, 1]$. Over $R = \mathbb{Z}$, the skein algebra $\mathcal{S}_R(\Sigma)$ is commutative and is closely related to the $SL_2(\mathbb{C})$-character variety of $\Sigma$, see [Bu, PS, Tu, BFK]. Over $R = \mathbb{Z}[q^{\pm 1}]$, $\mathcal{S}_R(\Sigma)$ is not commutative in general and is closely related to quantum Teichmüller spaces [CF].

2.3. **Bases.** We will consider $\Sigma$ as a subset of $\Sigma \times [0, 1]$ by identifying $\Sigma$ with $\Sigma \times \{1/2\}$. As usual, links in $\Sigma$, which are closed 1-dimensional non-oriented submanifolds of $\Sigma$, are considered up to ambient isotopies of $\Sigma$. A link $\alpha$ in $\Sigma$ is an *essential* if it has no trivial component, i.e. a component bounding a disk in $\Sigma$. By convention, the empty set is considered an essential link. The framing
of a link is *vertical* if at every point $x$, the framing is parallel to $x \times [0,1]$, with the direction equal to the positive direction of $[0,1]$. 

By [PS] Theorem 5.2, $\mathcal{J}_R(\Sigma)$ is free over $R$ with basis the set of all isotopy classes of essential links in $\Sigma$ with vertical framing. This basis can be parameterized as follows. An *integer lamination* of $\Sigma$ is an unordered collection $\mu = (n_i, C_i)_{i=1}^{m}$, where

- each $n_i$ is a positive integer
- each $C_i$ is a non-trivial knot in $\Sigma$
- no two $C_i$ intersect
- no two $C_i$ are ambient isotopic.

For each integer lamination $\mu$, define an element $b_\mu \in \mathcal{J}_R(\Sigma)$ by

$$b_\mu = \prod_{i} (C_i)^{n_i}.$$ 

Then the set of all $b_\mu$, where $\mu$ runs the set of all integer laminations including the empty one, is the above mentioned basis of $\mathcal{J}_R(\Sigma)$.

Suppose $P = (P_n(t))_{n \geq 0}$ is a normalized sequence of polynomials in $R[t]$. Then we can twist the basis element $b_\mu$ by $P$ as follows. Let

$$b_{\mu,P} := \prod_i P_{n_i}(C_i).$$

As $\{P_n(t) \mid n \in \mathbb{Z}_+\}$, just like $\{z^n\}$, is a basis of $R[t]$, the set $B_P$ of all $b_{\mu,P}$, when $\mu$ runs the set of all integer laminations, is a free $R$-basis of $\mathcal{J}_R(\Sigma)$.

### 3. Theorem 1.2 and its stronger version

We present here the proof of a stronger version of Theorem 1.2 using a result from [Le1] which we recall first.

#### 3.1. Skein algebra of the annulus.

Let $A \subset \mathbb{R}^2$ be the annulus $A = \{ x \in \mathbb{R}^2, 1 \leq |x| \leq 2 \}$. Let $z$ be the core of the annulus defined by $z = \{x, |x| = 3/2\}$. It is easy to show that, as an algebra, $\mathcal{J}_R(A) = R[z]$.

Let $p_1 = (0, 1) \in \mathbb{R}^2$ and $p_2 = (0, 2) \in \mathbb{R}^2$, which are points in $\partial A$. Then $A_{io} = (A, \{p_1, p_2\})$ is an example of a marked surface. See Figure 3 which also depicts the arcs $\theta_0, \theta_{-1}, \theta_2$. Here $\theta_0$ is the straight segment $p_1 p_2$, and $\theta_n$, for $n \in \mathbb{Z}$, is an arc properly embedded in $A$ beginning at $p_1$ and winding clockwise (resp. counterclockwise) $|n|$ times if $n \geq 0$ (resp. $n < 0$) before getting to $p_2$.

![Figure 3. Marked annulus $A_{io}$, arcs $\theta_0, \theta_{-1}, \theta_2$, and element $\theta_0 \cdot z$](image)

A $A_{io}$-arc is a proper embedding of the interval $[0, 1]$ in $A \times [0,1]$ equipped with a framing such that one end point is in $p_1 \times [0,1]$ and the other is in $p_2 \times [0,1]$, and the framing is vertical at both end points. A $A_{io}$-tangle is a disjoint union of a $A_{io}$-arc and a (possibly empty) framed link in $A \times [0,1]$. Isotopy of $A_{io}$-tangles are considered in the class of $A_{io}$-tangles.
Let $\mathcal{S}', R(\mathcal{A})$ be the $R$-module spanned by isotopy classes of $\mathcal{A}$-tangles modulo the usual skein relation and the trivial knot relation. As usual, each $\theta_n$ is equipped with the vertical framing, and is considered as an element of $\mathcal{S}', R(\mathcal{A})$.

For $\alpha \in \mathcal{S}, R(\mathcal{A})$ let $\theta_0 \cdot \alpha \in \mathcal{S}', R(\mathcal{A})$ be the element obtained by placing $\theta_0$ on top of $\alpha$, see Figure 3 for an example. In [Le1] we proved the following.

**Proposition 3.1.** For any integer $n \geq 1$, we have

\[
\theta_0 \cdot T_n(z) = q^n \theta_n + q^{-n} \theta_{-n}.
\]

**3.2. Stronger version of Theorem 3.2.** We say that a sequence $P = (P_n(t))$ of normalized polynomials in $R[t]$ is positive for $\Sigma$ over $R$ if $B_P$ is a positive basis for $\mathcal{S}(\Sigma)$. Thus, $P = (P_n(t))$ is positive if and only if it is positive for any oriented surface.

Theorem 1.2 follows from the following stronger statement.

**Theorem 3.2.** Suppose $P = (P_n(t))$ is positive for a non-planar oriented surface $\Sigma$. Then for every $n \geq 0$, $P_n(t)$ is an $R_+$-linear combination of $T_k(t)$ with $k \leq n$. Besides, $P_1(t) = t$.

**Proof.** Since $\Sigma$ is non-planar, there are two simple closed curves $z, z' \subset \Sigma$ which intersect transversally at one point. We identify a small tubular neighborhood of $z$ with the annulus $A$ such that $z' \cap A$ is the segment $p_1 p_2$, see Figure 4. Note that $z$ and $z'$, as homology classes in $H_1(\Sigma, \mathbb{Z})$, are linearly independent over $\mathbb{Z}$.

![Figure 4](image)

Figure 4. The union $A \cup z'$. The bold arc is $z' \setminus A$.

By definition $P_1(t) = t + a$, $a \in R$. Fix an integer $n \geq 1$. There are $c_k \in R$ such that

\[
P_n(t) = \sum_{k=0}^n c_k T_k(t).
\]

Let $z_{1,k}$ be the curve $(z' \setminus A) \cup \theta_k$. We have

\[
P_1(z')P_n(z) = aP_n(z) + z' \sum_{k=0}^n c_k T_k(z) = aP_n(z) + c_0 z' + \sum_{k=1}^n c_k z'T_k(z)
\]

\[
= aP_n(z) + c_0 z' + \sum_{k=1}^n c_k \left( q^k z_{1,k} + c_k q^{-k} z_{1,-k} \right)
\]

where the last equality follows from Proposition 3.1. Using homology, one sees that in the collection \{ $z, z', z_{1,k}, z_{1,-k}$ | $k \geq 1$ \} every curve is a non-trivial knot in $\Sigma$, and any two of them are non-isotopic.
Rewriting \( t = P_1(t) - a \), we have

\[
P_1(z')P_n(z) = aP_n(z) + c_0(P_1(z') - a) + \sum_{k=1}^n c_k \left[ q^k(P_1(z_{1,k}) - a) + q^{-k}(P_1(z_{1,-k}) - a) \right]
\]

\[
= aP_n(z) + c_0 P_1(z') + \sum_{k=1}^n c_k \left[ q^k(P_1(z_{1,k}) + q^{-k}(P_1(z_{1,-k}) - ac_0 - \sum_{k=1}^n ac_k(q^k + q^{-k}).
\]

By the positivity, the coefficients of \( P_1(z') \), \( P_n(z) \), \( P_1(z_{1,k}) \) (for every \( k \geq 1 \)) and the constant coefficient are in \( R_+ \). This shows that \( a, c_k \in R_+ \) for every \( k \), and

\[
d := -ac_0 - \sum_{k=1}^n ac_k(q^k + q^{-k}) \in R_+.
\]

Note that \(-d = a(c_0 + \sum_{k=1}^n c_k(q^k + q^{-k})) \in R_+\), since \( a, c_k \in R_+ \). Thus, both \( d \) and \(-d\) are in \( R_+ \). Then \( d = 0 \) by the assumption on \( R \). It follows that

\[
a(c_0 + \sum_{k=1}^n c_k(q^k + q^{-k})) = 0.
\]

**Claim.** Suppose \( x, y \in R_+ \) such that \( x + y = 0 \). Then \( x = y = 0 \).

*Proof of Claim.* We have \( x = -y \). Thus, \( y \) and \(-y = x\) are in \( R_+ \), implying \( y = 0 \). Then \( x = 0 \).

The claim means that if \( x, y \in R_+ \) and \( x \neq 0 \), then \( x + y \neq 0 \). In particular, \( q^n + q^{-n} \neq 0 \). Note that \( c_n = 1 \) because \( P_n(t) \) is a monic polynomial. All the summands in the sum

\[
c_0 + \sum_{k=1}^n c_k(q^k + q^{-k})
\]

are in \( R_+ \), and the summand with \( k = n \) is non-zero. Hence the above sum is non-zero. Since \( R \) is a domain, from (3) we conclude that \( a = 0 \). This completes the proof of the theorem. \( \square \)

4. Marked Surfaces

4.1. **Skein algebra of marked surfaces.** Suppose \((\Sigma, \mathcal{P})\) is a marked surface, i.e. \( \mathcal{P} \subset \partial \Sigma \) is a finite set. A **framed 3D \( \mathcal{P} \)-tangle** \( \alpha \) in \( \Sigma \times [0,1] \) is a framed proper embedding of a 1-dimensional non-oriented compact manifold into \( \Sigma \times [0,1] \) such that \( \partial \alpha \subset \mathcal{P} \times [0,1] \), and the framing at every boundary point of \( \alpha \) is vertical. Two framed 3D \( \mathcal{P} \)-tangles are **isotopic** if they are isotopic through the class of framed 3D \( \mathcal{P} \)-tangles.

Just like the link case, a framed 3D \( \mathcal{P} \)-tangle \( \alpha \) is depicted by its diagram on \( \Sigma \), with vertical framing on the diagram. Here a diagram of \( \alpha \) is a projection of \( \alpha \) onto \( \Sigma \) in general position, with an order of strands at every crossing. Crossings come in two types. If the crossing is in \( \Sigma \setminus \mathcal{P} \), then it is a usual double point (with usual over/under information). If the crossing is a point in \( \mathcal{P} \), there may be two or more number of strands, which are ordered. The order indicates which strand is above which. When there are two strands, the lower one is depicted by a broken line, see e.g. Figure 5.

Let \( \mathcal{I}_R(\Sigma, \mathcal{P}) \) be the \( R \)-module spanned by the set of isotopy classes of framed 3D \( \mathcal{P} \)-tangles in \( \Sigma \times [0,1] \) modulo the skein relation, the trivial knot relation (Figure 1), and the trivial arc relation of Figure 5.

The following relation holds, see \([Le2]\).

**Proposition 4.1.** In \( \mathcal{I}(\Sigma, \mathcal{P}) \), the reordering relation depicted in Figure 4 holds.
4.2. Basis for $\mathcal{R}_R(\Sigma, \mathcal{P})$. A $\mathcal{P}$-arc is an immersion $\alpha : [0, 1] \to \Sigma$ such that $\alpha(0), \alpha(1) \in \mathcal{P}$ and the restriction of $\alpha$ onto $(0, 1)$ is an embedding into $\Sigma \setminus \mathcal{P}$. A $\mathcal{P}$-knot is an embedding of $S^1$ into $\Sigma \setminus \mathcal{P}$. A $\mathcal{P}$-knot or a $\mathcal{P}$-arc is trivial if it bounds a disk in $\Sigma$. Two $\mathcal{P}$-arcs (resp. $\mathcal{P}$-knots) are $\mathcal{P}$-isotopic if they are isotopic in the class of $\mathcal{P}$-arcs (resp. $\mathcal{P}$-knots).

A $\mathcal{P}$-arc is called boundary if it can be isotoped into $\partial \Sigma$, otherwise it is called inner. We consider every $\mathcal{P}$-arc and every $\mathcal{P}$-knot as an element of $\mathcal{R}_R(\Sigma, \mathcal{P})$ by equipping it with the vertical framing.

In the case when the two ends of a $\mathcal{P}$-arc are the same point $p \in \mathcal{P}$, we order the left strand to be above the right one.

An integer $\mathcal{P}$-lamination of $\Sigma$ is an unordered collection $\mu = (n_i, C_i)_{i=1}^m$, where

- each $n_i$ is a positive integer
- each $C_i$, called a component of $\mu$, is a non-trivial $\mathcal{P}$-knot or a non-trivial $\mathcal{P}$-arc
- no two $C_i$ intersect in $\Sigma \setminus \mathcal{P}$
- no two $C_i$ are $\mathcal{P}$-isotopic.

In an integer $\mathcal{P}$-lamination $\mu = (n_i, C_i)_{i=1}^m$, a knot component commutes with any other component (in the algebra $\mathcal{R}_R(\Sigma, \mathcal{P})$), while a $\mathcal{P}$-arc component $C$ $q$-commutes with any other component $C'$ in the sense that $CC' = q^kC'C$ for a certain $k \in \mathbb{Z}$. The $q$-commutativity follows from Proposition 4.1. Hence the element

$$b_\mu = \prod_i (C_i)^{n_i}$$

is defined up to a factor $q^k, k \in \mathbb{Z}$. To make $b_\mu$ really well-defined, we will fix once and for all a total order on the set of all $\mathcal{P}$-arcs in $\Sigma$. Now define $b_\mu$ by (4), where the product is taken in this order. To simplify some proofs, we further assume that in the total order any boundary $\mathcal{P}$-arc comes before any inner $\mathcal{P}$-arc, although this is not necessary.

It follows from \cite[Lemma 4.1]{Mu} that the set of all $b_\mu$, where $\mu$ runs the set of all integer $\mathcal{P}$-laminations including the empty one, is the a free $R$-basis of $\mathcal{R}_R(\Sigma, \mathcal{P})$.

Suppose $\mathcal{P} = (P_n)$ and $\mathcal{Q} = (Q_n)$ are normalized sequences of polynomials in $R[t]$. Define

$$b_{\mu, \mathcal{P}, \mathcal{Q}} = \prod_i F_{n_i}(C_i),$$

where the product is taken in the above mentioned order, and
• $F_{n_i} = P_{n_i}$ if $C_i$ is a knot,
• $F_{n_i} = Q_{n_i}$ if $C_i$ is an inner $P$-arc,
• $F_{n_i}(C_i) = (C_i)^{n_i}$ if $C_i$ is a boundary $P$-arc.

Then the set $\mathcal{B}_{P, Q}$ of all $b_{\mu, P, Q}$, where $\mu$ runs the set of all integer $P$-laminations, is a free $R$-basis of $\mathcal{I}_R(\Sigma, P)$. A pair of sequences of polynomials $(P, Q)$ are positive over $R$ if they are normalized and the basis $\mathcal{B}_{P, Q}$ is positive for any marked surface.

4.3. Positive basis in quotients. The following follows right away from the definition.

Lemma 4.2. Let $B$ be a positive basis of an $R$-algebra $A$ and $I \subset A$ be an ideal of $A$, with $\pi : A \to A/I$ the natural projection. Assume that $I$ respects the base $B$ in the sense that $I$ is freely $R$-spanned by $I \cap B$. Then $\pi(B \setminus I)$ is a positive basis of $A/I$.

4.4. Ideal generated by boundary arcs.

Lemma 4.3. Suppose $a_1, \ldots, a_l$ are boundary $P$-arcs, and $I = \sum_{i=1}^l a_i \mathcal{I}_R(\Sigma, P)$.

(a) The set $I$ is a 2-sided ideal of $\mathcal{I}_R(\Sigma, P)$.

(b) For any normalized sequences $(P, Q)$ of polynomials in $R[t]$, $I$ respects the basis $\mathcal{B}_{P, Q}$.

Proof. (a) Suppose $a$ is a boundary $P$-arc. Since $a$ $q$-commutes with any basis element $b_\mu$ defined by (4), $a \mathcal{I}_R(\Sigma, P)$ is a 2-sided ideal of $\mathcal{I}_R(\Sigma, P)$. Hence $I$ is also a 2-sided ideal.

(b) In the chosen order, the boundary $P$-arcs come before any inner arcs $P$-arc. Hence $I$ is freely $R$-spanned by all $b_{\mu, P, Q}$ such that $\mu$ has one of the $\alpha_i$ as a component. Thus, $I$ respects $\mathcal{B}_{P, Q}$. □

4.5. Proof of Theorem 1.3. We will prove the following stronger version of Theorem 1.3.

Theorem 4.4. Suppose a pair $(P, Q)$ of sequences of polynomials in $R[t]$, $P = (P_n(t))_{n \geq 0}$ and $Q = (Q_n(t))_{n \geq 0}$, are positive over $R$. Then $P_n(t)$ is an $R_+\text{-linear combination of } T_0(t), T_1(t), \ldots, T_n(t)$ and $Q_n(t)$ is an $R_+\text{-linear combination of } 1, t, \ldots, t^n$. Moreover, $P_1(t) = Q_1(t) = t$.

Lemma 4.5. One has $Q_1(t) = t$.

![Figure 7](image-url) Left: $\mathbb{D}_1$, with product $xy$. Middle: $\mathbb{D}_5$, with product $x^2y_5$. Right: Element $z_{2,5}$

Proof. Consider the marked surface $\mathbb{D}_1$, which is a disk with 4 marked points $p_0, p_1, p_2$ and $q_1$ as in Figure 7. Let $x$ be the arc $p_0p_2$ and $y$ the arc $p_1q_1$. Suppose $Q_1(t) = t + a$, where $a \in R$. Using the skein relation to resolve the only crossing of $xy$, we get

$$Q_1(x)Q_1(y) = aQ_1(x) + aQ_1(y) - a^2 \mod I_0.$$ (6)

Here $I_0$ is the ideal of $\mathcal{I}_R(\mathbb{D}_1)$ generated by all the boundary $P$-arcs, which respects $\mathcal{B}_{P, Q}$ by Lemma 1.3, Lemma 4.2 and Equ. 3 show that $a \in R_-$ and $-a^2 \in R_+$. Hence both $a^2$ and $-a^2$ are $R_+$, which implies $a = 0$. □
Now fix an integer number $n \geq 2$. Let $D_n$ be the marked surface, which is a disk with $2n + 2$ marked points which in clockwise orders are $p_0, p_1, \ldots, p_{n+1}, q_n, \ldots, q_1$. We draw $D_n$ in the standard plane so that the straight segment $p_0p_{n+1}$, denoted by $x$, is vertical with $p_0$ being lower than $p_{n+1}$, and each straight segment $p_iq_i$ is horizontal. See Figure 7 for an example of $D_5$. Let $y_n$ be the union of the $n$ straight segments $p_iq_i$, $i = 1, \ldots, n$. Considering $x$ as an element of $\mathcal{S}R(D_n)$, we will present $x$ by $k$ arcs, each going from $p_0$ monotonously upwards to $p_{n+1}$. Any two of these $k$ arcs do not have intersection in the interior of $D_n$, and the left one is above the right one. See an example in Figure 7 where the diagram of $x^2y_5$ is drawn. Then the diagram of $x^ky_n$ has exactly $kn$ double points. Let $z_{k,n}$ be obtained from this diagram of $x^ky_n$ by negatively resolving all the crossings, again see Figure 7.

For each $i = 0, \ldots, n - 1$ let $\gamma_i$ be the arc $p_ip_{i+1}$, which is a boundary $\mathcal{P}$-arc. By Lemma 4.3, the set

$$I := \sum_{i=0}^{n-1} \gamma_i \mathcal{S}(\Sigma, \mathcal{P})$$

is a 2-sided ideal of $\mathcal{S}(\Sigma, \mathcal{P})$ respecting $B_{\mathcal{P}, \mathcal{Q}}$. It is important that the arc $p_{n+1}$ is not in $I$.

**Lemma 4.6.** For every $k \leq n$, one has

\begin{equation}
(7) \quad x^ky_n = q^{-kn}z_{k,n} \mod I.
\end{equation}

**Proof.** Label the $k$ arcs of the diagram of $x^k$ from left to right by $1, \ldots, k$. There are $kn$ crossings in the diagram of $x^ky_n$, and denote by $E_{l,m}$ the intersection of the $l$-th arc of $x^k$ and the arc $p_mq_m$ of $y_n$. Order the set of all $kn$ crossings $E_{lm}$ by the lexicographic pair $(l + m, l)$.

Suppose $\tau$ is one of the $2^{kn}$ ways of resolutions of all the $kn$ crossings. Let $D_\tau$ be the result of the resolution $\tau$, which is a diagram without crossing. Assume $\tau$ has at least one positive resolution. We will prove that $D_\tau \in I$. Let $E_{l,m}$ be the smallest crossing at which the resolution is positive. In a small neighborhood of $E_{l,m}$, $D_\tau$ has two arcs, with the lower left one denoted by $\delta$, see Figure 8.

- **Figure 8.** Left: Crossing $E_{l,m}$. Right: Its positive resolution, and the arc $\delta$.

The resolution at any $E_{l,m'} < E_{l,m}$ is negative. These data are enough to determine the arc $u$ of $D_\tau$ containing $\delta$, see Figure 9. Namely, if $m \geq l$ then $u$ is $\gamma_{m-l}$, and if $m < l$ then $u$ is an arc whose two end points are $p_0$, which is $0$. See Figure 10 for an example. Either case, $D_\tau \in I$.

- **Figure 9.** The top right corner crossing is $E_{l,m}$, with positive resolution. The arc of $D_\tau$ containing $\delta$ keeps going down the south-west direction.
Figure 10. Left: The arc \( u \) with \( l = 4, m = 5 \). In this case \( u = \gamma_1 \). Right: The arc \( u \) with \( l = 4, m = 3 \). In this case, both end points of \( u \) are \( p_0 \).

Hence, modulo \( I \), the only element obtained by resolving all the crossings of \( x^k y_n \) is the all-negative resolution one, which is \( z_{k,n} \). The corresponding factor coming from the skein relation is \( q^{-kn} \). This proves Identity (7). \( \square \)

Proof of Theorem 4.4. Theorem 3.2 implies that \( P_n \) is an \( R_+ \)-linear combination of \( T_k \) with \( k \leq n \).

Since \( Q_1(t) = t \), each of \( z_{k,n}, y_n \) in Lemma 4.6 is an element of the basis \( \mathcal{B}_{\mathcal{P},Q} \).

Suppose \( Q_n(t) = \sum_{k=0}^{n} c_k t^k \) with \( c_k \in R \). From (7), we have

\[
Q_n(x)y_n = \left( \sum_{k=0}^{n} c_k x^k \right) y_n = \sum_{k=0}^{n} c_k q^{-kn} z_{k,n} + I.
\]

Note that \( z_{k,n} \notin I \). Since \( I \) respects the basis \( \mathcal{B}_{\mathcal{P},Q} \), Lemma 4.2 shows that \( c_k \in R_+ \) for all \( k \). This completes the proof of Theorem 4.4. \( \square \)
