On different notions of calibrations for minimal partitions and minimal networks in $\mathbb{R}^2$

May 30, 2018

Abstract

Calibrations are a possible tool to validate the minimality of a certain candidate. They have been introduced by Harvey and Lawson in [9] and adapted to the case of Steiner problem in several variants. Our goal is to compare the different notions of calibrations for the Steiner Problem and for planar minimal partitions appeared in [10, 11, 6]. The paper is then complemented with remarks on the convexification of the problem, on nonexistence of calibrations and on calibrations in families.

1 Introduction

Let us call $S$ a collection of $n$ points $p_1, \ldots, p_n$ in the Euclidean plane. We want to find a connected set that contains $S$ whose length is minimal, namely

$$\inf\{\mathcal{H}^1(K) : K \subset \mathbb{R}^2, \text{ connected and such that } S \subset K\}.$$  (1.1)

This latter is commonly known as Steiner problem.

Although existence of minimizers is known, finding explicitly a solution is extremely challenging even numerically. For this reason every method to determine solutions is welcome. A tool is the notion of calibrations, introduced in the context of minimal surfaces by Harvey and Lawson in their paper *Calibrated Geometries* [9]: given $M$ a $k$-dimensional oriented manifold in $\mathbb{R}^d$, a calibration for $M$ is a closed $k$-form $\omega$ such that $|\omega| \leq 1$ and $\langle \omega, \xi \rangle = 1$ for every $\xi$ in the tangent space of $M$. Then the existence of a calibration for $M$ implies that the manifold is area minimizing in its homology class. Indeed given an oriented $k$-dimensional manifold $N$ such that $\partial M = \partial N$ we have

$$\text{Vol}(M) = \int_M \omega = \int_N \omega \leq \text{Vol}(N),$$

where we applied the properties required on the calibration $\omega$ and we used Stokes theorem in the second equality.

This definition of calibration is not suitable for the Steiner Problem (1.1) simply for the reason that neither the competitors nor the minimizers of the problem are smooth manifolds. We are anyhow dealing with union of curves in the plane, objects that are “nearly smooth”, hence one

*Institut für Mathematik, Universität Graz, Heinrichstrae 36, 8010 Graz, Austria
†Fakultät für Mathematik, Universität Regensburg, Universitätstraße 31, 93053 Regensburg, Germany
is tempted to find a suitable adjustment of the previously notion. Indeed several variants have been defined starting from the paired calibrations by Morgan and Lawlor in [10] where Steiner is seen as a problem of minimal partitions. Then in [11] Marchese and Massaccesi rephrase the Steiner Problem as a mass minimization for 1–rectifiable currents with coefficients in a group and this leads to a suitable definition of calibrations (see also [4]). Finally reviving the approach via covering space by Brakke [5] (see [2] for the existence theory) another notion of calibrations has been produced [6].

A natural question is whether the notions of calibrations are equivalent. When the points of $S$ lay on the boundary of a convex set (actually the only case in which paired calibrations are defined) calibrations on coverings are nothing else than paired calibrations. Instead an equivalence does not exist between calibrations on coverings and calibrations for currents with coefficient in $\mathbb{R}^n$; in particular the notion of calibrations for currents is stronger than the one on coverings. In other words it is easier to find a calibration on coverings.

Let us now discuss in more depth on the relation between the two notions. The definition of calibrations for currents with coefficients in $\mathbb{R}^n$ (see Definition 2.14) depends on choice of the norm of $\mathbb{R}^n$. The norm considered in [11] (here denoted by $\| \cdot \|_b$) is the one that produces the weakest notion of calibrations and still gives the equivalence with the Steiner problem in $\mathbb{R}^d$ with $d \geq 2$: the “best” possible norm in a certain sense. These calibrations are in fact stronger than the calibrations on coverings. Indeed in Theorem 3.2 we are able to prove that if a calibration for a mass minimizing current exists, then there exists also a calibration for a perimeter minimizing set in a given covering, but the converse does not hold. To prove a sort of vice versa one has to abandon the idea of working in the general setting of Marchese and Massaccesi [11] and take all the advantages of restricting to $\mathbb{R}^2$. To this aim we slightly change the mass minimization problem and we define a different norm on $\mathbb{R}^n$ denoted by $\| \cdot \|_\nabla$ (the unit ball of $\| \cdot \|_\nabla$ is smaller than the one of $\| \cdot \|_b$ as one can see (at least in $\mathbb{R}^3$) from their Frank diagram depicted in Figure 2). The consequent notion of calibration is suitable only in $\mathbb{R}^2$ and equivalent with the definition of calibrations on coverings.

The second part of the paper has a different focus and it can be seen as a completion of [6] as we restrict our attention only on calibrations on coverings. In Theorem 4.2 we prove that the existence of a calibration for a constrained set $E$ in a covering $Y$ implies the minimality of $E$ not only among (constrained) finite perimeter sets, but also in the larger class of finite linear combinations of characteristic functions of finite perimeter sets (satisfying a suitable constraint). This apparently harmless result has some remarkable consequences. First of all it is directly related with the convexification of the problem naturally associated with the notion of calibration. This convexification $G$ is the so–called “local convex envelope” and it has been defined by Chambolle, Cremers and Pock. In [7] they are able to prove that it is the tightest among the convexifications with an integral form. Unfortunately it does not coincide with the convex envelope of the functional, whose characterization is unknown. We show that $G$ equals the total variation on constrained BV functions with a finite number of values. In other words, the local convex envelope ”outperforms” the total variation only when evaluated on constrained BV functions whose derivative has an absolutely continuous part with respect to $L^2$.

As a second consequence of Theorem 4.2 we produce a counterexample to the existence of calibrations. It has already been exhibit in the setting of normal currents by Bonafini [3] and because of the result of Section 3 we had to “translate” it in our framework. It is specific of the case in which $S$ is composed of five points, vertices of a regular pentagon and cannot be
easily generalized to vertices of regular polygons.

We summarize here the structure of the paper. In Section 2 we recap the different approaches to Steiner Problem and the consequent notions of calibrations. Section 3 is devoted to the relations among different definitions of calibrations. Then in Section 4 we improve the Theorem “existence of calibrations implies minimality” and this allows us to complement a result by Chambolle, Cremers and Pock on the convexification of the problem. An example of non existence of calibrations is given in Section 5. The paper is concluded with some remarks about the calibrations in families presented in [6] that underline the effectiveness of our method.

2 Notions of calibrations for minimal Steiner networks

In this section we briefly review the approaches to the Steiner Problem that lead to the notions of calibrations presented in the literature [10, 11, 6].

2.1 Covering space approach

We begin by explaining the approach via covering space by Brakke [5] and Amato, Bellettini and Paolini [2]. They proved that minimizing the perimeter among constrained sets on a suitable defined covering space of $\mathbb{R}^2 \setminus S := M$ is equivalent to minimize the length among all networks that connects the point of $S$. We refer to both [2] and [6] for details.

Let us call the covering space $(Y, p)$ where $p : Y \rightarrow M$ is the projection onto the base space. Consider $\ell$ a loop in $\mathbb{R}^2$ around at most $n - 1$ points of $S$. Heuristically $Y$ is composed of $n$ copies of $\mathbb{R}^2$ (the sheets of the covering space) glued in such a way that following $p^{-1}(\ell)$, one visits all the $n$ sheets. We avoid to repeat here the explicit construction of $Y$ presented in [2] but it is relevant to keep in mind how points of different copies of $\mathbb{R}^2 \setminus S$ are identified. First the $n$ points of $S$ are connected with a cut $\Sigma \subset \Omega$ given by the union of injective Lipschitz curves $\Sigma_i$ from $p_i$ to $p_{i+1}$ (with $i \in \{1, \ldots, n-1\}$) not intersecting each others. Then $\Sigma_i$ is lifted in all the $n$ sheets of $M$ and the points of $\Sigma_i$ of the $j$–th sheet are identified with points of $\Sigma_i$ of the $k$–th sheet via the equivalence relation

$$k \equiv j + i \pmod{n} \quad \text{with} \quad i = 1, \ldots, n - 1 \quad \text{and} \quad j = 1, \ldots, n.$$ 

This equivalence relation produces a non–trivial covering of $M$.

![Figure 1: A closer look at the topology of the covering $Y$ of $\mathbb{R}^2 \setminus \{p_1, p_2, p_3\}$. Each ball is represented with one texture and color.](image)

We remark that for technical reasons the construction in [2] requires the definition of a pair of cuts joining the point $p_i$ with $p_{i+1}$. Then the equivalence relation is defined identifying the open sets enclosed by the pairs of cuts.
Remark 2.1. Given a function \( f : Y \to \mathbb{R}^n \) it is possible to define the parametrizations of \( f \) on the sheet \( j \) as a function \( f^j : M \to \mathbb{R}^n \) for every \( j = 1, \ldots, m \) (see [6, Definition 2.5, Definition 2.6] for further details).

It is then possible to define functions \( f \) (resp. sets \( E \)) on the covering space \( Y \) prescribing the parametrizations \( f^j : M \to \mathbb{R}^n \) (resp. sets \( E^j \)) for every \( j = 1, \ldots, m \). The set \( E^j \) is the set determined by the parametrization of \( \chi_E \) on the sheet \( j \).

We define now the class of sets \( \mathcal{P}_{\text{constr}}(Y) \) that we will consider to get the equivalence with the Steiner Problem. A set \( E \) belongs to the space \( \mathcal{P}_{\text{constr}}(Y) \) if it is a set of finite perimeter in \( Y \), for almost every \( x \) in the base space there exists exactly one point \( y \) of \( E \) such that \( p(y) = x \) and it satisfies a suitable boundary condition.

More precisely fixing an open, regular and bounded set \( \Lambda \subset \mathbb{R}^2 \) such that \( \Sigma \subset \Lambda \) and \( \text{Conv}(S) \subset \Lambda \) (here \( \text{Conv}(S) \) denotes the convex envelope of \( S \)), we defined rigorously \( \mathcal{P}_{\text{constr}}(Y) \) as follows:

**Definition 2.2 (Constrained sets).** We denote by \( \mathcal{P}_{\text{constr}}(Y) \) the space of the sets of finite perimeter in \( Y \) such that

1. \( \sum_{p(y)=x} \chi_E(y) = 1 \) for almost every \( x \in M \),
2. \( \chi_{E^1}(x) = 1 \) for every \( x \in \mathbb{R}^2 \setminus \Lambda \).

We look for \( \min \{ P(E) : E \in \mathcal{P}_{\text{constr}}(Y) \} \). (2.1)

Remark 2.3. Problem (2.1) does not depend on the choice of the cut \( \Sigma \) in the definition of the covering space \( Y \) (see [2] for details). Moreover given \( E_{\text{min}} \) a minimizer for (2.1) it is always possible to label the points \( S \) with in such a way that the cut \( \Sigma \) does not intersect the projection of the reduced boundary of \( E_{\text{min}} \) (see [6, Proposition 2.28]). From now on we always do this choice of the labeling of \( S \).

Once reduced Steiner Problem to Problem (2.1), a notion of calibration follows extremely naturally. We employ the notion of *approximately regular* vector fields [6, Definition 5.1 and 5.2].

**Definition 2.4 (Calibration on coverings).** Given \( E \in \mathcal{P}_{\text{constr}}(Y) \), a calibration for \( E \) is an approximately regular vector field \( \tilde{\Phi} : Y \to \mathbb{R}^2 \) such that:

1. \( \text{div} \tilde{\Phi} = 0 \);
2. \( |\tilde{\Phi}^i(x) - \tilde{\Phi}^j(x)| \leq 2 \) for every \( i, j = 1, \ldots, n \) and for every \( x \in M \);
3. \( \int_Y \tilde{\Phi} \cdot D\chi_E = P(E) \).

As desired we have that if \( \tilde{\Phi} : Y \to \mathbb{R}^2 \) is a calibration for \( E \), then \( E \) is a minimizer of Problem (2.1) (see [6, Theorem 3.5]).

We remind that we can reformulate the problem in terms of \( BV \) functions with value in \( \{0, 1\} \): we define \( BV_{\text{constr}}(Y, \{0, 1\}) \) as the space of functions \( u \in BV(Y, \{0, 1\}) \) such that for almost every \( x \in M \) it holds \( \sum_{p(y)=x} u(y) = 1 \) and \( u^1(x) = 1 \) for every \( x \in \mathbb{R}^2 \setminus \Lambda \). Then we minimize the total variation among functions in \( BV_{\text{constr}}(Y, \{0, 1\}) \).
2.2 Minimal partitions problem and paired calibrations

We propose here the definition of paired calibration [10] of a minimal partition in the plane (see for example [7] for this formulation). To speak about minimal partitions and paired calibration we have to suppose that the points of $S$ lays on the boundary of an open smooth convex set $\Omega$.

We define $B := \left\{ u = (u_1, \ldots, u_n) \in BV(\Omega, \{0, 1\}^n) \text{ such that } \sum_{i=1}^{n} u_i(x) = 1 \text{ a.e. in } \Omega \right\}$

and a function $\overline{u} \in B$ such that $\overline{u}_i = 1$ on the part of $\partial \Omega$ that connects $p_i$ with $p_{i+1}$.

We then define the energy:

$$E(u) := \sum_{i=1}^{n} |Du_i|(\Omega).$$

Definition 2.5. A function $u_{\min} \in B$ is a minimizer for the partition problem if $u_{\min} = \overline{u}$ on $\partial \Omega$ and

$$E(u_{\min}) \leq E(v).$$

for every $v \in B$ such that $v = \overline{u}$ on $\partial \Omega$.

Definition 2.6 (Paired calibration). A paired calibration for $u \in B$ is a collection of $n$ approximately regular vector fields $\phi_1, \ldots, \phi_n : \Omega \to \mathbb{R}^2$ such that

- $\text{div} \phi_i = 0$ for every $i = 1, \ldots, n$,
- $|\phi_i - \phi_j| \leq 2$ a.e. in $\Omega$ and for every $i, j = 1, \ldots, n$,
- $(\phi_i - \phi_j) \cdot \nu_{ij} = \mathcal{H}^1$-a.e. in $J_{u_i} \cap J_{u_j}$ and for every $i, j = 1, \ldots, n$,

where $J_{u_i}$ is the jump set of the function $u_i$ and $\nu_{ij}$ denotes the normal to $J_{u_i} \cap J_{u_j}$.

With this definition Morgan and Lawlor proved in [10] that if there exists a paired calibration for a given $u \in B$, then the latter is a minimizer of the minimal partition problem according to Definition 2.5.

Given $u = (u_1, \ldots, u_n)$ a minimizer for the partition problem the union of the jump sets of $u_i$ is a minimal Steiner network. Vice versa given a minimal Steiner network it is possible to construct $v = (v_1, \ldots, v_n) \in B$ such that the union of the singular sets of $v_i$ is the network. Such a $v$ is a minimizer for the partition problem. Therefore Definition 2.6 is a legit calibration for Steiner Problem as well.

Remark 2.7. Calibrations on coverings in Definition 2.4 are a generalization of paired calibrations. Indeed when the points $S$ lays on the boundary of a convex set (the only case in which paired calibrations are defined) the two notions are equivalent. Suppose that the points of $S$ lay on the boundary of a convex set $\Omega$. Then in the construction of $Y$ we can choose the cut $\Sigma$ outside $\Omega$. Consider $u = (u_1, \ldots, u_n) \in B$ a minimizer for the minimal partition problem and a paired calibration $(\phi_1, \ldots, \phi_n)$ for $u$. Define then $\tilde{u} \in BV_{\text{constr}}(Y, \{0, 1\})$ prescribing the parametrization on each sheet of $Y$ as

$$\tilde{u}^i = u_{n+1-i} \quad \text{for } i = 1, \ldots, n.$$
Notice that with this choice $|D\tilde{u}|(Y) = \mathcal{E}(u)$. Define a vector field $\tilde{\Phi} : Y \to \mathbb{R}^2$ prescribing its parametrizations on the sheets of the covering spaces (see Remark 2.1) as

$$\tilde{\Phi}^i = \phi_{n+1-i} \quad \text{for } i = 1, \ldots, n.$$  

It is easy to check that $\tilde{u}$ is a minimizer for Problem 2.1 and that $\tilde{\Phi}$ a calibration for $\tilde{u}$ according to Definition 2.4. We underline that by its very definition the same $\tilde{\Phi}$ is a calibration for all minimizers of Problem 2.1.

Viceversa, repeating the same procedure explained before, given a calibration $\tilde{\Phi}$ for $\tilde{u} \in BV_{\text{constr}}(Y, \{0, 1\})$ minimizer for Problem (2.1) one can construct a paired calibration for $u \in B$ minimizer for the minimal partition problem.

### 2.3 Currents with coefficient in $\mathbb{R}^n$

Consider the normed space $(\mathbb{R}^n, \| \cdot \|)$ and denote by $\| \cdot \|_*$ the dual norm. For $k = 0, 1, 2$ we call $\Lambda_k(\mathbb{R}^2)$ the space of $k$–vectors in $\mathbb{R}^2$.

**Definition 2.8** ($k$–covector with values in $\mathbb{R}^n$). A $k$–covector with values in $\mathbb{R}^n$ is a linear map from $\Lambda_k(\mathbb{R}^2)$ to $\mathbb{R}^n$. We denote by $\Lambda^k_n(\mathbb{R}^2)$ the space of $k$–covectors with values in $\mathbb{R}^n$.

We define the comass norm of a covector $\omega \in \Lambda^k_n(\mathbb{R}^2)$ as

$$|\omega|_{\text{com}} := \sup \{ \| \omega(\tau) \|_* : \tau \in \Lambda_k(\mathbb{R}^2) \text{ with } |\tau| \leq 1 \text{ and } \tau \text{ simple} \}.$$  

Then the $k$–forms with values in $\mathbb{R}^n$ are defined as the vector fields $\omega \in C^\infty_c(\mathbb{R}^2, \Lambda^k_n(\mathbb{R}^2))$ and their comass is given by

$$\| \omega \|_{\text{com}} := \sup_{x \in \mathbb{R}^2} |\omega(x)|_{\text{com}}.$$  

**Remark 2.9.** Notice that the definition of the space $C^\infty_c(\mathbb{R}^2, \Lambda^k_n(\mathbb{R}^2))$ is equivalent to the one presented in [11]. Indeed they considered $k$–covector $\omega$ defined as bilinear maps

$$\omega : \Lambda_k(\mathbb{R}^2) \times \mathbb{R}^n \to \mathbb{R},$$  

that can be seen as $k$–covectors with values in $(\mathbb{R}^n)'$.

Thanks to the just defined notions we are able to introduce the definition of $k$–current with coefficients in $\mathbb{R}^n$.

**Definition 2.10** ($k$–current with coefficients in $\mathbb{R}^n$). A $k$–dimensional current with coefficients in $\mathbb{R}^n$ is a linear and continuous map

$$T : C^\infty_c(\mathbb{R}^2, \Lambda^k_n(\mathbb{R}^2)) \to \mathbb{R}.$$  

The boundary of a $k$–current $T$ with coefficients in $\mathbb{R}^n$ is a $k - 1$–current defined as

$$\partial T(\omega) := -T(d\omega),$$  

where $d\omega$ is defined component–wise.

**Definition 2.11** (Mass). Given $T$ a $k$–current with coefficients in $\mathbb{R}^n$ its mass is

$$M(T) := \sup \left\{ T(\omega) : \omega \in C^\infty_c(\mathbb{R}^2, \Lambda^k_n(\mathbb{R}^2)) \text{ with } \| \omega \|_{\text{com}} \leq 1 \right\}.$$
A \( k \)-current \( T \) with coefficients in \( \mathbb{R}^n \) is said to be **normal** if \( M(T) < \infty \) and \( M(\partial T) < \infty \).

**Definition 2.12** (1–rectifiable current with coefficients in \( \mathbb{Z}^n \)). Given \( \Sigma \) a 1–rectifiable set oriented by \( \tau \in \Lambda_1(\mathbb{R}^2) \), simple, such that \( |\tau(x)| = 1 \) for a.e. \( x \in \Sigma \) and \( \theta : \Sigma \to \mathbb{Z}^n \) in \( L^1(H^1) \), a 1–current \( T \) is rectifiable with coefficients in \( \mathbb{Z}^n \) if admits the following representation:

\[
T(\omega) = \int_{\Sigma} \langle \omega(x)(\tau(x)), \theta(x) \rangle \, dH^1.
\]

A 1–rectifiable current with coefficients in \( \mathbb{Z}^n \) will be denoted by the triple \( T = [\Sigma, \tau, \theta] \).

Notice that if \( T = [\Sigma, \tau, \theta] \) is a 1–rectifiable current with coefficients in \( \mathbb{Z}^n \) one can write its mass as

\[
M(T) = \int_{\Sigma} \|\theta(x)\| \, dH^1.
\]

**Remark 2.13.** The space of 1–covector with values in \( \mathbb{R}^n \) can be identified with the set of matrices \( M^{n \times 2}(\mathbb{R}) \). In what follows we will assume this identification and we will denote the set of 1–forms by \( C^\infty_c(\mathbb{R}^2, M^{n \times 2}(\mathbb{R})) \). Moreover given \( \omega \in C^\infty_c(\mathbb{R}^2, M^{n \times 2}(\mathbb{R})) \) we write it as

\[
\omega = \begin{bmatrix}
\omega_1(x) \\
\vdots \\
\omega_n(x)
\end{bmatrix},
\]

where \( \omega_i : \mathbb{R}^2 \to \mathbb{R}^2 \). Notice that \( \omega_i(x) \) is a canonical 1-form, hence its differential can be identified (by the canonical Hodge dual) as

\[
d\omega_i = \frac{\partial \omega_i}{\partial x_2} - \frac{\partial \omega_i}{\partial x_1} = \text{div} \omega_i^\perp
\]

and therefore we can define \( d\omega \) as

\[
d\omega = \begin{bmatrix}
\text{div} \omega_1^\perp \\
\vdots \\
\text{div} \omega_n^\perp
\end{bmatrix}.
\]

Let \( (g_i)_{i=1,\ldots,n-1} \) be the canonical base of \( R^{n-1} \). Define \( g_n = -\sum_{i=1}^{n-1} g_i \).

Given \( B = g_1 \delta_{p_1} + \ldots + g_n \delta_{p_n} \) we consider the following minimization problem:

\[
\inf \left\{ M(T) : T \text{ is a } 1 \text{--rectifiable currents with coefficients if } \mathbb{Z}^{n-1}, \partial T = B \right\}.
\] (2.2)

To have the equivalence between Problem (2.2) and the Steiner Problem (1.1) the choice of the norm of \( \mathbb{R}^{n-1} \) plays an important role. Indeed given \( \mathcal{I} \) any subset of \( \{1, \ldots, n-1\} \) we require that

\[
\left\| \sum_{i \in \mathcal{I}} g_i \right\| = 1.
\]

The notion of calibration associated to the mass minimization problem (2.2) introduced in [11] is the following:

**Definition 2.14** (Calibration for 1–rectifiable currents). Let \( T = [\Sigma, \tau, \theta] \) be a 1–rectifiable current with coefficients in \( \mathbb{Z}^{n-1} \) and \( \Phi \in C^\infty_c(\mathbb{R}^2, M^{n-1 \times 2}(\mathbb{R})) \). Then \( \Phi \) is a calibration for \( T \) if
(i) $d\Phi = 0$;
(ii) $\|\Phi\|_{com} \leq 1$;
(iii) $(\Phi(x)\tau(x), \theta(x)) = \|\theta(x)\|$ for $H^1$-a.e. $x \in \Sigma$.

If $\Phi \in C^\infty_c(\mathbb{R}^2, M^{n-1}x2(\mathbb{R}))$ is a calibration for $T = [\Sigma, \tau, \theta]$ a 1–rectifiable current with coefficients in $\mathbb{Z}^{n-1}$, then $T$ is a minimizer of Problem (2.2). To be more precise $T$ is a minimizer among normal currents with coefficients in $\mathbb{R}^{n-1}$ [11].

Remark 2.15. In Proposition 5.3 in appendix we prove that is possible to weaken the regularity of the calibration $\Phi$ and consider $\Phi : \mathbb{R}^2 \rightarrow M^{n-1}x2(\mathbb{R})$ such that each row is an approximately regular vector field. In the next section we assume implicitly that $\Phi$ is approximately regular.

3 Relations among the different notions of calibrations

We have already discussed the equivalence between paired calibrations and calibrations on coverings (see Remark 2.7). We focus now on the relation with Definition 2.14. Definition 2.14 is dependent on the norm of $\mathbb{R}^n$. Let us now define $\| \cdot \|_b$ as

$$
\|x\|_b := \sup_{x_i > 0} x_i - \inf_{x_i \leq 0} x_i
$$

for every $x \in \mathbb{R}^n$. This is the norm considered by Marchese and Massaccesi [11]. In [11] it is also proved that the dual norm $\| \cdot \|_b^*$ can be characterized as follows:

$$
\|x\|_{b^*} = \max \left\{ \sum_{x_i > 0} x_i, \sum_{x_i \leq 0} |x_i| \right\}. \quad (3.1)
$$

From here on we endow $\mathbb{R}^n$ with $\| \cdot \| = \| \cdot \|_b$. With this choice, we show that if there exists a calibration for a 1–rectifiable current with coefficient in $\mathbb{Z}^{n-1}$, then there exists a calibration for $E \in \mathcal{P}_{constr}$ minimizer for Problem (2.1).

Lemma 3.1. Given $S = \{p_1, \ldots, p_n\}$ with the points $p_i$ laying on the boundary of a convex set $\Omega$ labeled in an anticlockwise sense and $u = (u_1, \ldots, u_n)$ a competitor of the minimal partition problem, it is possible to construct a 1–rectifiable current $T$ with coefficients in $\mathbb{Z}^{n-1}$ such that $2\mathcal{M}(T) = \mathcal{E}(u)$ and $\partial T = g_1\delta_{p_1} + \ldots + g_n\delta_{p_n}$ where $(g_i)_{i=1, \ldots, n-1}$ is the canonical base of $\mathbb{R}^{n-1}$ and $g_n := \sum_{i=1}^{n-1} g_i$.

Proof. For $i = 1, \ldots, n$ let $A_i$ be the phases of the partition induced by $u = (u_1, \ldots, u_n)$, that is $u_i = \chi_{A_i}$. We fix $A_i$ to be the phase between the points $p_i$ and $p_{i+1}$. Notice that for every $i \in \{1, \ldots, n\}$ the set $\partial^* A_i$ is a 1–rectifiable set in $\mathbb{R}^2$ with tangent $\tau_i$ almost everywhere and it joins the points $p_i$ and $p_{i+1}$. For $i \in \{1, \ldots, n\}$ we define $T_i = [\partial^* A_i, \tau_i, a_i]$ where the multiplicities $a_i$ are chosen in such a way that $a_i - a_{i+1} = g_i$ for $i = 1, \ldots, n-1$. Then for every $i, j = 1, \ldots, n$

$$
a_i - a_j = \sum_{k=i}^{j-1} g_k. \quad (3.2)
$$
We set
\[ T = \sum_{i=1}^{n} T_i. \]

Denoting by \( \theta_T \) the multiplicity of \( T \), by construction \( \theta_T(x) = a_i - a_j \) for \( H^1 \)-a.e. \( x \in \partial^* A^i \cap \partial^* A^j \). Notice that \( \partial T_i = a_i(\delta_{p_i} - \delta_{p_{i+1}}) \) (with the convention that \( p_{n+1} = p_1 \)). Hence
\[
\partial T = \sum_{i=1}^{n} \partial T_i = \sum_{i=1}^{n} a_i(\delta_{p_i} - \delta_{p_{i+1}}) = \sum_{i=1}^{n} a_i \delta_{p_i} - \sum_{i=1}^{n} a_{i+1} \delta_{p_i+1} \\
= \sum_{i=1}^{n} a_i \delta_{p_i} - \sum_{i=2}^{n+1} a_{i-1} \delta_{p_{i-1}} = (a_1 - a_n) \delta_{p_1} + \sum_{i=2}^{n} (a_i - a_{i+1}) \delta_{p_i} \\
= \sum_{i=1}^{n} g_i \delta_{p_i}.
\]

\[\Box\]

**Theorem 3.2.** Given \( S = \{p_1, \ldots, p_n\} \) laying on the boundary of a convex set \( \Omega \), let \( E \in \mathcal{P}_{\text{constr}} \) be a minimizer for Problem (2.1). Let \( \Phi \) be a calibration according to Definition 2.14 for \( T = [\Sigma, \tau, \theta] \) a 1-rectifiable current with coefficients in \( \mathbb{Z}^{n-1} \) minimizer of Problem (2.2). Then there exists \( \tilde{\Phi} \) a calibration for \( E \) (according to Definition 2.4).

**Proof.** We label the \( n \) points of \( S \) in an anticlockwise sense. In this case calibrations on coverings 2.4 reduce to paired calibrations 2.6. Hence we are looking for a collection \( \tilde{\Phi} \) of \( n \) vector fields \( \tilde{\Phi}^i : \Omega \to \mathbb{R}^2 \) for \( u = (u_1, \ldots, u_n) \in B \) where \( u_{n+1-i} = \chi_{E^i} \) (see Remark 2.7).

Let \( \Phi_i \) be the \( n - 1 \) rows of the matrix \( \Phi \). We claim that the collection of \( n \) vector fields \( \tilde{\Phi}^i \) defined by the following relations
\[ \tilde{\Phi}^i - \tilde{\Phi}^{i+1} = 2\Phi^i \perp \text{ for } i = 1, \ldots, n - 1 \]
(3.3)
is a calibration for \( E \). Notice that from (3.3) we deduce that
\[ \tilde{\Phi}^n - \tilde{\Phi}^1 = -2 \sum_{i=1}^{n-1} \Phi^i \perp. \]

We have to show that \( \Phi \) satisfies conditions (1), (2), (3).

(1) The divergence of \( \tilde{\Phi} \) is automatically zero, because \( \text{div} \, \tilde{\Phi}^i = 0 \) in \( \Omega \) for every \( i = 1, \ldots, n \) (Notice that we have taken the cut \( \Sigma \) outside \( \Omega \)).

(2) By Definition 2.14 it holds that \( \|\Phi\|_{\text{com}} \leq 1 \), hence for every \( x \in \mathbb{R}^2 \) we have
\[
\sup \left\{ \|\Phi(x)\tau\|_{b,s} \mid \tau \in \mathbb{R}^2, |\tau| \leq 1 \right\} \leq 1.
\]
Writing the \( n \) components of \( \Phi(x)\tau \) as \( (\Phi_1(x), \tau), \ldots, (\Phi_n(x), \tau) \) and using (3.1), for every \( \tau \in \mathbb{R}^2 \) such that \( |\tau| \leq 1 \) and \( i, j = 1, \ldots, n \) with \( i \leq j - 1 \) we obtain
\[
1 \geq \|\Phi(x)\tau\|_{b,s} = \max \left\{ \sum_{(\Phi_k, \tau) > 0} (\Phi_k, \tau), - \sum_{(\Phi_k, \tau) < 0} (\Phi_k, \tau) \right\} \\
\geq \sum_{k=1}^{n-1} (\Phi_k, \tau) = \left| \sum_{k=1}^{j-1} (\Phi_k, \tau) \right|. 
\]

9
Therefore
\[ | \sum_{k=i}^{j-1} \Phi_k | \leq 1. \]

Notice that from (3.3) we obtain that for every \( i, j \in \{1, \ldots, n\} \)
\[ |\tilde{\Phi}_i - \tilde{\Phi}_j| = 2 | \sum_{k=i}^{j-1} \Phi_k |. \]

Hence for every \( i, j \in \{1, \ldots, n\} \) condition \(|\tilde{\Phi}_i(x) - \tilde{\Phi}_j(x)| \leq 2\) is fulfilled for almost every \( x \in \Omega \).

(3) In this case there is a one-to-one a correspondence between sets \( E \in \mathcal{P}_{\text{constr}} \) and \( u = (u_1, \ldots, u_n) \in \mathcal{B} \). In particular we can apply the construction of Lemma 3.1 with \( E^i = A_{n+1-i} \) produce a 1-rectifiable current \( T \) with coefficients in \( \mathbb{Z}^{n-1} \) such that and \( \partial T = \partial T \) and \( 2M(T) = P(E) \). Moreover thanks to the fact that \( E \) a minimizer for (2.1) and \( T \) for (2.2) we get
\[ 2M(T) = P(E) = 2H^1(S) = 2M(T), \]
where \( S \) is a minimizer for the Steiner Problem (1.1). The current \( T \) has the same boundary and the same mass of \( T \), then it is a minimizer for the Problem (2.2) as well. Therefore \( \Phi \) is a calibration also for \( T \). Then we have that \( H^1\text{-a.e. } x \in \mathcal{P}(\partial^* E) \)
\[ \langle \Phi_\tau, \theta_T \rangle = 1. \]

Using (3.2), for \( H^1\text{-a.e. } x \in \partial^* A^i \cap \partial^* A^j \) the previous equation reads as
\[ 1 = \langle \Phi_\tau, \sum_{k=i}^{j-1} g_k \rangle = \sum_{k=i}^{j-1} \langle \Phi_\tau, g_k \rangle = \sum_{k=i}^{j-1} \langle \Phi_k, \tau \rangle = \sum_{k=i}^{j-1} \langle \Phi_k^\perp, \nu_{ij} \rangle = \frac{1}{2} \langle \tilde{\Phi}_i - \tilde{\Phi}_j, \nu_{ij} \rangle, \]
that is the third condition of the paired calibration, that in our setting is equivalent to (3) of Definition 2.14.

When the points of \( S \) do not lay on the boundary of a convex set, we cannot take advantage of the equivalence between calibrations on coverings and paired calibrations (that are not defined if the points of \( S \) are not on the boundary of a convex set). Indeed in this case we look for a unique vector field \( \tilde{\Phi} : Y \to \mathbb{R}^2 \) defined on the whole space \( Y \) and satisfying the requirements of Definition 2.4. As one can guess from Step (3) in the proof of Theorem 3.2, relations (3.3) has to be satisfied locally around the jumps. A clue of this fact is the local equivalence between the minimal partition problem and Problem (2.1) that suggests a local equivalence between calibrations on coverings and paired calibrations. Thanks to Remark 2.1 once defined \( \tilde{\Phi}^i \) in each sheet one can construct \( \tilde{\Phi} \), but in doing such an extension/identification procedure it is not guaranteed that the divergence of \( \tilde{\Phi} \) is zero. It seems to us that the existence of a calibration \( \tilde{\Phi} \) is plausible, but the extension of the field has to be treated case by case. At the moment we do not have an algorithm to construct \( \tilde{\Phi} \) globally.
Given a calibration for $E \in \mathcal{P}_{\text{constr}}$ minimizer for Problem (2.1) we try now to construct a calibration for $T$, a 1–rectifiable current with coefficient in $\mathbb{Z}^{n-1}$ minimizer for Problem (2.2). Notice that Condition ii) of Definition 2.14 can be equivalently written as

$$\langle \Phi(x) \tau(x), \theta(x) \rangle \leq \| \theta(x) \|_{\flat} \quad \text{for } \mathcal{H}^1 \text{ a.e } x \in \Sigma$$

and for any competitor $\overline{T} = [\Sigma, \tau, \theta]$. Moreover it suffices to evaluate $\langle \Phi(x) \tau(x), \cdot \rangle$ on the extremal points of the unit ball of the norm $\| \cdot \|_{\flat}$ that are $P_I = \sum_{i \in I} g_i$ for every $I \subseteq \{1, \ldots, n-1\}$ (see [11, Example 3.4]). Hence proving Condition ii) reduces to verify $2^{n-1} - 1$ inequalities. On the other hand Condition (2) of Definition 2.4 requires to verify $n(n-1)/2$ inequalities. Apart from the case of 2 and 3 points Condition (2) of Definition 2.4 is weaker than Condition ii) of Definition 2.14. Hence in general one cannot construct a calibration for $T$ starting from a calibration for $E$.

To restore an equivalence result we slightly change Problem (2.2). We define a norm $\| \cdot \|_{\#}$ on $\mathbb{R}^n$ characterized by the property that its unit ball is the smallest such that

$$\left\| \sum_{k=i}^{j-1} g_i \right\|_2 = 1 \quad \text{with } i \leq j - 1 \in \{1, \ldots, n\}.$$

From now on we write either $M_{\#}$ or $M_\flat$ to distinguish when the mass is computed using either the norm $\| \cdot \|_2$ or $\| \cdot \|_\flat$. We have the following lemma.

![Figure 2: Left: the unit ball of the norm $\| \cdot \|_\flat$. Right: the unit ball of the norm $\| \cdot \|_2$.](image)

**Lemma 3.3.** We call

$$\mathcal{G} := \left\{ \sum_{k=i}^{j-1} g_k : i, j = 1, \ldots, n \text{ and } i \leq j - 1 \right\}.$$

There exists a permutation $\sigma$ of the labeling of the points of $S$ such that defining

$$B_\sigma = \sum_{i=1}^{n-1} g_{\sigma(i)} \delta_{p_{\sigma(i)}}$$

11
the problem

\[
\inf \{ M_{2}(T) : T = [\Sigma, \tau, \theta] \text{ is a 1–rectifiable currents with coefficients if } \mathbb{Z}^{n-1}, \\
\partial T = B_{\sigma} \text{ and } \theta(x) \in \mathcal{G} \} \tag{3.4}
\]

is equivalent to the Steiner Problem.

We obtain the definition of calibration for Problem (3.4) simply repeating Definition 2.14 replacing \( \| \cdot \|_{b} \) by \( \| \cdot \|_{2} \). Clearly if \( \Phi \) is a calibration for \( T_{\sigma} \), then \( T_{\sigma} \) is a minimizer for Problem (3.4) in its homology class. We are now in position to state the result.

**Theorem 3.4.** Given \( S = \{p_{1}, \ldots, p_{n}\} \), let \( E \in \mathcal{P}_{\text{constr}} \) be a minimizer for Problem (2.1) and \( T = [\Sigma, \tau, \theta] \) be a 1–rectifiable current with coefficients in \( \mathbb{Z}^{n-1} \) minimizer of Problem (3.4). Suppose that there exists \( \Phi \) calibration for \( E \) according to Definition 2.14, then there exists \( \Phi \) calibration for \( T_{\sigma} \) according to Definition 2.14 (where we consider \( \| \cdot \| = \| \cdot \|_{2} \)).

**Proof.** For simplicity we suppose that the \( n \) points lay on the boundary of a convex set \( \mathcal{C} \) hence \( \Phi : \mathcal{C} \to \mathbb{R}^{2} \) reduces to a paired calibration: a collection of \( n \) vector fields \( \Phi^{i} : \mathcal{C} \to \mathbb{R}^{2} \).

We define \( \Phi \) calibration for \( T_{\sigma} \) as the matrix whose \( n - 1 \) rows satisfy

\[
\Phi^{i} = \frac{1}{2} (\tilde{\Phi}^{i} - \tilde{\Phi}^{i+1}) \quad \text{for } i = 1, \ldots, n - 1.
\]

The Condition i) is trivially satisfied and adapting the proof of step (3) of Theorem 4.2 we also get Condition iii). To conclude the proof it is enough to notice that when \( \mathbb{R}^{n} \) is endowed with \( \| \cdot \|_{2} \) condition \( \| \Phi \|_{\text{com}} \leq 1 \) is fulfilled if \( \sum_{k=i}^{j-1} \Phi^{k} \leq 1 \) for every \( i \leq j - 1 \in \{1, \ldots, n\} \), that is nothing else than \( |\tilde{\Phi}^{i} - \tilde{\Phi}^{i+1}| \leq 2 \).

We conclude this section proving Lemma 3.3.

**Proof of Lemma 3.3.**

Denoted by \( S \) a Steiner network connecting the points of \( S \) we repeat the construction of [6, Proposition 2.28] that gives us a suitable labeling of the points of \( S \) (and consequently \( B_{\sigma} \)) and \( E \in \mathcal{P}_{\text{constr}} \) minimizer for Problem 2.1 such that \( \mathcal{H}^{1}(S) = p(\partial^{*}E) \). Following the procedure of point (3) of Theorem 4.2 we construct \( T_{\sigma} = [\Sigma_{\sigma}, \tau_{\sigma}, \theta_{\sigma}] \) with boundary \( B_{\sigma} \) such that \( \theta_{\sigma} \in \mathcal{G} \) and \( M_{3}(T_{\sigma}) = p(\partial^{*}E) = \mathcal{H}^{1}(S) \). Hence by the equivalence between Steiner problem and Problem (2.2) the current \( T_{\sigma} = [\Sigma_{\sigma}, \tau_{\sigma}, \theta_{\sigma}] \) is a minimizer for Problem (2.2). We show that \( T_{\sigma} \) is a minimizer also for Problem (3.4). By minimality of \( T_{\sigma} \) it holds \( M_{3}(T_{\sigma}) \leq M_{3}(T) \) for all 1–rectifiable current \( T \) with coefficients in \( \mathbb{Z}^{n-1} \) and hence in particular for all the competitors of Problem (3.4). Moreover the mass \( M_{3} \) for all the competitors of Problem (3.4) coincides with the mass \( M_{3} \). Then for all competitors \( T \) it holds

\[
M_{3}(T_{\sigma}) = M_{3}(T_{\sigma}) \leq M_{3}(T) = M_{3}(T),
\]

that gives the minimality of \( T_{\sigma} \) for Problem (3.4) and concludes the proof.

**Remark 3.5.** Despite in general giving explicitly the permutation \( \sigma \) is quite hard, the choice of a suitable labeling of the points of \( S \) becomes easy when the points lay on the boundary of a convex set: it is enough to label \( p_{1}, \ldots, p_{n} \) in an anticlockwise sense. Indeed we can easily convince ourselves that any branch of a rectifiable current with multiplicity \( g_{k} + g_{l} \) with \( k \) and \( l \) non consecutive is not contained in the convex. Then this current is surely not a minimizer of Problem 2.2: its support cannot be a minimal Steiner network which is fully contained in the convex.
4 Convexifications of the problem

Definition 4.1. We call

- $BV_{\text{constr}}(Y, [0, 1])$ the space of functions $u \in BV(Y, [0, 1])$ such that for almost every $x \in M$ it holds $\sum_{p(y)=x} u(y) = 1$ and $u^i(x) = 1$ for every $x \in \mathbb{R}^2 \setminus \Omega$.
- $BV^#_{\text{constr}}(Y)$ the space of functions in $BV_{\text{constr}}(Y, [0, 1])$ with a finite number of values $\alpha_1, \ldots, \alpha_k$.

In [6] we have proven that if $\Phi$ is a calibration for $u \in BV_{\text{constr}}(Y, \{0, 1\})$, then $u$ is a minimizer in the same class, but actually holds the following:

**Theorem 4.2.** If $\Phi : Y \to \mathbb{R}^2$ is a calibration for $u \in BV_{\text{constr}}(Y, \{0, 1\})$, then $u$ is a minimizer among all functions in $BV^#_{\text{constr}}(Y)$.

For the proof of Theorem 4.2 we need the following:

**Lemma 4.3.** Let $\{\eta_i\}_{i=1}^m$ and $\{t_i\}_{j=1}^m$ such that $\sum_{i=1}^m \eta_i = 0$ and $|t_i - t_j| \leq 2$ for every $i, j \in 1 \ldots, m$. Then

$$\left| \sum_{i=1}^m t_i \eta_i \right| \leq \sum_{i=1}^m |\eta_i| \quad (4.1)$$

**Proof.** Notice that

$$\left| \sum_{i=1}^m t_i \eta_i \right| = \left| \sum_{\eta_i > 0} t_i \eta_i + \sum_{\eta_i < 0} t_i \eta_i \right| \leq \left| \sum_{\eta_i > 0} \max(t_i) \eta_i + \sum_{\eta_i < 0} \min(t_i) \eta_i \right| =$$

$$= \left| \sum_{\eta_i > 0} \max(t_i) \eta_i - \sum_{\eta_i > 0} \min(t_i) \eta_i \right| \leq 2 \left| \sum_{\eta_i > 0} \eta_i \right| = \sum_{i=1}^m |\eta_i|.$$

$\square$

**Remark 4.4.** We also note that given $u, w \in BV_{\text{constr}}(Y, [0, 1])$ and $\Phi : Y \to \mathbb{R}^2$ an approximately regular divergence free vector field it holds

$$\int_Y \Phi \cdot Du = \int_Y \Phi \cdot Dw. \quad (4.2)$$

This result can be proved adapting [6, Proposition 4.3].

**Proof of Theorem 4.2.**
Consider $u \in BV_{\text{constr}}(Y, \{0, 1\})$, $\Phi : Y \to \mathbb{R}^2$ a calibration for $u$ and $w$ a competitor in $BV^#_{\text{constr}}(Y)$. Combining Remark 4.4 with Conditions (1) and (3) of Definition 2.4 we have

$$|Du|(Y) = \int_Y \Phi \cdot Du = \int_Y \Phi \cdot Dw. \quad (4.3)$$

Moreover by the representation formula for $Dw$ in the space $Y$ we get

$$\int_Y \Phi \cdot Dw = \sum_{j=1}^m \int_D \Phi^j \cdot Dw^j.$$
where without loss of generality we have supposed that \( p(J_w) \cap \Sigma = \emptyset \).

Calling \( \eta_j(x) = (w^j)^+(x) - (w^j)^-(x) \), we notice that, as \( w \in BV_{\text{constr}}(Y) \), for almost every \( x \in D \)

\[
\sum_{i=1}^m \eta_i(x) = 0.
\]

Then

\[
\sum_{j=1}^m \int_D \Phi^j \cdot Dw^j = \sum_{j=1}^m \int_{j \cap D} \eta_j \Phi^j \cdot \nu \, dH^1
\]

\[
= \int_{p(J_w) \cap D} \sum_{j=1}^m \eta_j(\Phi^j \cdot \nu) \chi_{J_{w^j}} \, dH^1
\]

\[
\leq \int_{p(J_w) \cap D} \left| \sum_{j=1}^m \Phi^j \eta_j \chi_{J_{w^j}} \right| \, dH^1.
\]

Applying Lemma 4.3 one obtains

\[
\int_Y \Phi \cdot Dw \leq \int_{p(J_w) \cap D} \sum_{j=1}^m |\eta_j| \chi_{J_{w^j}} \, dH^1 = |Dw|(Y).
\]

(4.4)

Hence combining (4.3) with (4.4) we conclude that

\[
|Du|(Y) = \int_Y \Phi \cdot Du = \int_Y \Phi \cdot Dw \leq |Dw|(Y).
\]

\[\square\]

Remark 4.5. The previous theorem is sharp, in the sense that one cannot replace \( BV_{\text{constr}}(Y) \) by \( BV_{\text{constr}}(Y, [0,1]) \). Indeed consider \( S = \{p_1, p_2, p_3\} \) with \( p_i \) vertices of an equilateral triangle. Despite the minimizer \( u \in BV_{\text{constr}}(Y, [0,1]) \) is calibrated (for the result in our setting see [6, Example 3.8]), there exists a function in \( BV_{\text{constr}}(Y, [0,1]) \setminus BV_{\text{constr}}^\#(Y) \) whose total variation is strictly less than the total variation of \( u \), as it shown in [7, Proposition 5.1].

We define now the convexification of \( |Du| \) with \( u \in BV_{\text{constr}}(Y, [0,1]) \) naturally associated to the notion of calibration for covering spaces. It was introduced by Chambolle, Cremers and Pock in [7] in the context of minimal partitions.

Definition 4.6 (Local convex envelope). Let \( u \in BV_{\text{constr}}(Y, [0,1]) \). We consider the functional \( G \) given by

\[
G(u) := \int_Y \Psi(Du)
\]

where

\[
\Psi(q) = \sup_{p \in K} \sum_{j=1}^k p^j \cdot q^j
\]

and

\[
K = \{ p \in Y : \| p^j - p^i \| \leq 2, \text{ for every } i, j = 1, \ldots, k \}.
\]

In analogy with [7] we call \( G \) local convex envelope.
The local convex envelope is the tightest convexification with an integral form, indeed:

**Proposition 4.7.** ([?]) The local convex envelope $G$ is the larger convex integral functional of the form $H(v) = \int_Y \Psi(x, Dv)$ with $v \in BV_{\text{constr}}(Y, [0, 1])$ and $\Psi(x, \cdot)$ non negative, even and convex such that

$$H(v) = |Dv|(Y) \quad \text{for } v \in BV_{\text{constr}}(Y, \{0, 1\}).$$

As a consequence of Theorem 4.2 we are able to prove:

**Proposition 4.8.** It holds

$$G(v) = |Dv|(Y) \quad \text{for } v \in BV^\#_{\text{constr}}(Y).$$

**Proof.** The inequality $G(v) \geq |Dv|(Y)$ is consequence of Proposition 4.7 choosing $\Psi(x, p) = |p|$. For the other inequality it is just enough to notice that given $v \in BV_{\text{constr}}(Y)$, from the proof of Theorem 4.2 we obtain that

$$\int_Y p \cdot Dv \leq |Dv|(Y)$$

for every $p \in K$. Therefore taking the supremum on both sides and using that $|Dv|(Y) < +\infty$ we conclude that

$$\int_Y \sup_{p \in K} p \cdot Dv \leq |Dv|(Y).$$

**Remark 4.9.** Proposition 4.8 shows that even if the local convex envelope is the best integral convexification of the problem, it ”outperforms” the total variation only when evaluated on functions $u \in BV_{\text{constr}}(Y, [0, 1]) \setminus BV^\#_{\text{constr}}(Y)$.

### 5 An example of non existence of calibrations

Finding a calibration for a candidate minimizer is not an easy task. We wanted to understand at least whether there exists a calibration when $S$ is composed of points lying at the vertices of a regular polygon. We have a positive answer only in the case of a triangle and of a square [11, 6]. As a byproduct of Theorem 4.2 we are now able to negatively answer in the case of a regular pentagon.

**Example 5.1 (Five vertices of a regular pentagon).** Given $S = \{p_1, \ldots, p_5\}$ with $p_i$ the five vertices of a regular pentagon, the minimizer of the Steiner problem is well known. Following the canonical construction presented in [6, Proposition 2.28] it is not difficult to construct the ”associated” function $u \in BV_{\text{constr}}(Y, \{0, 1\})$ here represented in Figure 3. By explicit computations one gets $\frac{1}{2}|Du|(Y) = 4.7653$. Consider now the function $w \in BV_{\text{constr}}(Y, \{0, \frac{1}{2}, 1\})$ exhibited in Figure 3. It holds $\frac{1}{2}|Dw|(Y) \approx 4.5677$. Theorem 4.2 tells us that if a calibration for the minimizer $u$ exists, then $u$ has to be a minimizer also in the larger space $BV^\#_{\text{constr}}(Y)$, but $|Dw|(Y) < |Du|(Y)$, hence a calibration for $u$ does not exists.

Non–existence of calibrations for minimal currents when $S = \{p_1, \ldots, p_5\}$ with $p_i$ the five vertices of a regular pentagon was already highlighted in [3, Example 4.2]. As we have shown that Definition 2.14 is stronger than Definition 2.4 it was necessary to ”translate” the example in our setting to conclude that a calibration does not exists for $u$ minimizer of Problem (2.1).
5.1 Remarks on calibrations in families

Example 5.1 underlines an big issue of the theory of calibrations. Calibrations in families (see \[6, Section 4\]) can avoids the problem. Indeed in \[6, Example 4.9\] we are able to find the minimal Steiner network for the five vertices of a regular pentagon via a calibration argument. We explain briefly here the strategy we used and we validate it with some remarks.

- First we divide the sets of \(P_{\text{constr}}(Y)\) in families. The competitors that belong to the same class share a property related to the projection of their essential boundary onto the base set \(M\). In particular we define a family as
  \[
  \mathcal{F}(J) := \{ E \in P_{\text{constr}}(Y) : H^1(E_{i,j}) \neq 0 \text{ for every } \{i, j\} \in J \}.
  \]
  where \(J \subset \{1, \ldots, m\} \times \{1, \ldots, m\}\) and \(E_{i,j} := \partial^* E^i \cap \partial^* E^j\). The union of the families has to cover \(P_{\text{constr}}(Y)\).

- We consider a suitable notion of calibrations for \(E\) in \(\mathcal{F}(J)\): Condition (2) can be weaken as
  \[
  |\Phi^i(x) - \Phi^j(x)| \leq 2 \text{ for every } i, j = 1, \ldots, m \text{ such that } \{i, j\} \in J \text{ and for every } x \in D.
  \]

- We calibrate the candidate minimizer in each family.

- We compare the perimeter of each calibrated minimizer to find the explicit global minimizers of Problem (2.1).

How to divide the competitors in families

We consider as competitors only the sets in \(P_{\text{constr}}(Y)\) whose projection onto \(M\) is a network without loops. This choice is not restrictive.

Suppose that \(S\) consists of \(n\) points located on the boundary of a convex set \(\Omega\). Then Problem (2.1) is equivalent to a minimal partition problem and \(E \in P_{\text{constr}}(Y)\) induces a partition \(\{A_1, \ldots, A_n\}\) of \(\Omega\). The \(A_i\) are usually called phases. We classify the sets in \(P_{\text{constr}}(Y)\) simply prescribing which phases “touch” each other (see \[6, Lemma 4.8\]). The division in families depends on the topology of the complementary of the network.

Let us now pass to the general case of any configuration of \(n\) points of \(S\). The minimal Steiner networks are composed of at most \(m = 2n - 3\) segments. Each segment of a minimizer \(S\)
coincides with $p(E^{ij})$ for $i \neq j \in \{1, \ldots, n\}$. Different segments of $S$ are associated with different $E^{ij}$. We take $I$ composed of $2n - 3$ different couples of indices $(i, j) \in \{1, \ldots, n\} \times \{1, \ldots, n\}$. The cover of $\mathcal{P}_{\text{const}}(Y)$ is given by considering all possible $I$ satisfying the above property.

One can also consider more coarse classifications of the competitors, Condition (2) becomes weaker as well.

Existence of calibrations in families
The just proposed division in families is the finest one and it classify the competitors relying on their topological type. The advantage is that the minimizer is unique in each family thanks to the convexity of the distance within any combinatorial type. As a consequence it is possible to prove that a calibration in such a families always exists.

Identification of local minimizers
A stationary point for the length functional is a finite union of segments that meet at multiple points where the unit tangent vectors of the curves sum up to zero. A stationary point is stable if and only if it presents only triple junctions where the curves form equal angles of 120 degrees. We notice that the calibrated minimizers in $\mathcal{F}(J)$ are stable critical points. Our method allows us to find all the stable critical points without loops.

Export the idea of calibrations in families to currents
Once identified the families for sets in $\mathcal{P}_{\text{const}}(Y)$ it is possible to produce families for Problems (2.2) and (3.4). Take a competitor in each $\mathcal{F}(J)$. When the points of $S$ lay on the boundary of a convex set it is sufficient to apply Lemma 3.1 (reminding that $E_i = A_{n+1-i}$) to construct a current $T$. Then one can identify the coefficients of $T$. Hence in this case the classification in families will rely on which subsums of $g_i$ are present in the competitors.

To deal with the case of general configurations of points of $S$, we have to generalize Lemma 3.1. In the construction we set $T_i = [\partial^{*} E^i, \tau_i, e_i]$ where $\tau_i$ are the rotated of $-\pi / 2$ of the outer normal vectors to $\partial^{*} E^i$ and the multiplicities are chosen in such a way that $e_i - e_{i-1} = \tilde{g}_i$ with $\tilde{g}_i$ linearly independent vectors of $\mathbb{R}^{n-1}$. Again we set $T = \sum T_i$. Now $\partial T$ is the sum of $\tilde{g}_j \delta_{p_i}$ with $j$ can also be different from $i$. We obtain a current with the desired boundary simply substituting $\tilde{g}_j$ with $g_i$ in order to satisfy $\tilde{g}_j \delta_{p_i} = g_i \delta_{p_i}$.

Appendix: Regularity of the calibration

**Proposition 5.2** (Constancy theorem for currents with coefficients in $\mathbb{R}^n$). Let $T$ be a normal 2-current in $\mathbb{R}^2$ with coefficients in $\mathbb{R}^n$. Then there exists $u \in BV(\mathbb{R}^2, \mathbb{R}^n)$ such that for every $\omega \in C_c^\infty(\mathbb{R}^2, \mathbb{R}^n)$

$$T(\omega) = \int_{\mathbb{R}^2} \langle \omega, u \rangle \, dL^2. \tag{5.1}$$

**Proof.** Notice firstly that the space of 2–forms with values in $\mathbb{R}^n$ can be identified by Hodge duality to the space $C_c^\infty(\mathbb{R}^2, \mathbb{R}^n)$. As $T$ is a normal current, by Riesz theorem there exists $\sigma : \mathbb{R}^2 \rightarrow \mathbb{R}^n$ and $\mu_T$ a finite measure in $\mathbb{R}^2$ such that

$$T(\omega) = \int_{\mathbb{R}^2} \langle \omega, \sigma \rangle \, d\mu_T = \sum_{i=1}^n \int_{\mathbb{R}^2} \omega_i \sigma_i \, d\mu_T. \tag{5.2}$$
Defining $T_i : C^\infty_c(\mathbb{R}^2, \mathbb{R}) \to \mathbb{R}$ as

$$T_i(f) = \int_{\mathbb{R}^2} f \sigma_i \, d\mu_T$$

we know that $T_i$ is a 2-normal current with coefficients in $\mathbb{R}$. Therefore we can apply the standard constancy theorem (see for example [8]) and find $u_i \in BV(\mathbb{R}^2)$ such that

$$T_i(f) = \int_{\mathbb{R}^2} f u_i \, d\mathcal{L}^2$$

(5.3)

for every $i = 1, \ldots, n$. Hence combining (5.2) and (5.3) we conclude. □

**Theorem 5.3.** Suppose that $\Phi : \mathbb{R}^2 \to M^{n \times 2}(\mathbb{R})$ is a matrix valued vector field such that its rows are approximately regular vector fields. Given $T = [\Sigma, \tau, \theta]$ a 1-rectifiable current with coefficients in $\mathbb{Z}^n$, assume that $\Phi$ satisfies condition (i), (ii) and (iii) of Definition 2.14. Then $T$ is mass minimizing among all rectifiable 1-currents with coefficient in $\mathbb{Z}^n$ in its homology class.

**Proof.** Set $\Omega' \subset \subset \Omega \subset \mathbb{R}^2$ open, bounded, smooth sets such that they contain the convex envelope of $S$. Given the candidate minimizer $T$ we take a competitor $\tilde{T} = [\tilde{\Sigma}, \tilde{\tau}, \tilde{\theta}]$: a rectifiable 1-current in $\mathbb{R}^2$ with coefficients in $\mathbb{Z}^n$ such that $\partial(T - \tilde{T}) = 0$. Notice that we can suppose that $\Sigma, \tilde{\Sigma} \subset \Omega'$. There exists $U$ a normal 2-current in $\mathbb{R}^2$ with coefficients in $\mathbb{Z}^n$ such that $T - \tilde{T} = \partial U$. By Proposition 5.2 there exists $u \in BV(\mathbb{R}^2, \mathbb{R}^n)$ such that for every $\omega \in C^\infty_c(\mathbb{R}^2, \mathbb{R}^n)$

$$U(\omega) = \int_{\mathbb{R}^2} \langle \omega, u \rangle \, d\mathcal{L}^2.$$  

Notice that for every $\phi \in C^\infty_c(\mathbb{R}^2, M^{n \times 2})$ supported in $\mathbb{R}^2 \setminus \Omega'$ we have

$$0 = T(\phi) - \tilde{T}(\phi) = -U(d\phi) = -\int_{\mathbb{R}^2} \langle u, d\phi \rangle \, d\mathcal{L}^2 = \sum_{i=1}^n \int_{\mathbb{R}^2} u_i \text{div} \phi_i^\perp \, d\mathcal{L}^2.$$ 

Taking the supremum on $\phi \in C^\infty_c(\mathbb{R}^2, M^{n \times 2})$ compactly supported in $\mathbb{R}^2 \setminus \Omega'$ such that $\|\phi\|_\infty \leq 1$ we infer that $|Du|(\mathbb{R}^2 \setminus \Omega') = 0$ and therefore there exists a vector $c \in \mathbb{R}^n$ such that $u(x) = c$ in $\mathbb{R}^2 \setminus \Omega'$ almost everywhere. Define then

$$U_0(\omega) = \int_{\mathbb{R}^2} \langle \omega, u^c \rangle \, d\mathcal{L}^2$$  

(5.4)

where $u^c(x) = u(x) - c$. It is easy to check that $U_0(d\phi) = U(d\phi)$ for every $\phi \in C^\infty_c(\mathbb{R}^2, M^{n \times 2})$.

Define now $\Phi_n \in C^\infty_c(\mathbb{R}^2, M^{n \times 2})$ as $\Phi_n = (\chi_{\Omega} \Phi) * \rho_n$, where $\rho_n$ is a mollifier. Using the standard divergence theorem for BV function we obtain

$$T(\Phi_n) - \tilde{T}(\Phi_n) = \partial U(\Phi_n) = -U(d\Phi_n) = -U_0(d\Phi_n) = -\int_{\mathbb{R}^2} \langle u^c, d\Phi_n \rangle \, d\mathcal{L}^2 = -\sum_{i=1}^n \int_{\mathbb{R}^2} u_i^c \text{div} (\Phi_n)_i^\perp \, d\mathcal{L}^2 = \sum_{i=1}^n \int_{\mathbb{R}^2} (\Phi_n)_i^\perp \cdot Du_i^c.$$  

(5.5)

We observe that

$$T(\Phi_n) = \int_{\Sigma} \langle \Phi_n \tau, \theta \rangle \, d\mathcal{H}^1 \to T(\Phi) \quad \text{as} \ n \to +\infty$$
because $\Sigma \subset \Omega$ and similarly for $\widetilde{T}$. Therefore taking the limit on both sides of (5.5) we get
\[
T(\Phi) - \widetilde{T}(\Phi) = \sum_{i=1}^{n} \int_{\Omega} \Phi_{i}^{\perp} \cdot Du_{i}^{c}.
\]
Finally applying the divergence theorem for approximately regular vector fields ([1]) and using that $u^{c} = 0$ on $\mathbb{R}^2 \setminus \Omega'$ we get
\[
T(\Phi) - \widetilde{T}(\Phi) = \sum_{i=1}^{n} \int_{\Omega} u_{i}^{c} \text{div} \Phi_{i}^{\perp} d\mathcal{L}^{2} = 0
\]
thanks to property (i) of a calibration.

Then the proof follows the same line of Proposition 3.2 in [11].
