Department of Anesthesiology, Fatih University School of Medicine, Ankara, Turkey.

PURPOSE: The aim of this study was to evaluate the effect of dexmedetomidine on shivering during spinal anesthesia.

METHODS: Sixty patients (American Society of Anesthesiologists physical status I or II, aged 18-50 years), scheduled for elective minor surgical operations under spinal anesthesia with hyperbaric bupivacaine, were enrolled. They were administered saline (group C, n = 30) or dexmedetomidine (group D, n = 30). Motor block was assessed using a Modified Bromage Scale. The presence of shivering was assessed by a blinded observer after the completion of subarachnoid drug injection.

RESULTS: Hypothermia was observed in 21 patients (70%) in group D and in 20 patients (66.7%) in group C (p = 0.781). Three patients (10%) in group D and 17 patients (56.7%) in group C experienced shivering (p = 0.001). The intensity of shivering was lower in group D than in group C (p = 0.001). Time from baseline to onset of shivering was 10 (5-15) min in group D and 15 (5-45) min in group C (p = 0.207).

CONCLUSION: Dexmedetomidine infusion in the perioperative period significantly reduced shivering associated with spinal anesthesia during minor surgical procedures without any major adverse effect during the perioperative period. Therefore, we conclude that dexmedetomidine infusion is an effective drug for preventing shivering and providing sedation in patients during spinal anesthesia.

KEYWORDS: Dexmedetomidine; Shivering; Spinal anesthesia.

INTRODUCTION

Shivering is defined as an involuntary, repetitive activity of skeletal muscles. The mechanisms of shivering in patients undergoing surgery are mainly intraoperative heat loss, increased sympathetic tone, pain, and systemic release of pyrogens. Spinal anesthesia significantly impairs the thermoregulation system by inhibiting tonic vasoconstriction, which plays a significant role in temperature regulation. Spinal anesthesia also causes redistribution of core heat from the trunk (below the block level) to the peripheral tissues. These two effects predispose patients to hypothermia and shivering. The median incidence of shivering related to regional anesthesia observed in a review of 21 studies is 55%. Shivering increases oxygen consumption, lactic acidosis, carbon dioxide production, and metabolic rate by up to 400%. Therefore, shivering may cause problems in patients with low cardiac and pulmonary reserves. The best way to avoid these intraoperative and postoperative shivering-induced increases in hemodynamic and metabolic demands is to prevent shivering in the first place. Although dexmedetomidine is among several pharmacological agents used for the treatment of shivering, its effects on prevention of shivering during central neuraxial blockade have not been evaluated to date. Dexmedetomidine is a highly selective α2-adrenoceptor agonist with potent effects on the central nervous system. Henceforth, the aim of this study was to evaluate the effect of dexmedetomidine on shivering during spinal anesthesia.

MATERIALS AND METHODS

Sixty patients (American Society of Anesthesiologists physical status I or II, aged 18-50 years), scheduled for elective minor surgical operations under spinal anesthesia, were enrolled in the study. Patients with thyroid disease, Parkinson’s disease, dysautonomia, Raynaud’s syndrome, cardiopulmonary disease, a history of allergy to the agents to be used, a need for blood transfusion during surgery, an initial core temperature >37.5°C or <36.5°C, a known history of alcohol use, use of sedative-hypnotic agents, use of vasodilators, or having contraindications to spinal
anesthesia were excluded from the study. The Local Ethics Committee approved the study protocol, and all subjects gave written consent to participate. The temperature of the operating room was maintained at 21°C to 22°C (measured by a wall thermometer). Irrigation and i.v. fluids were administered at room temperature and given without in-line warming. All patients were covered with one layer of surgical drapes over the chest, thighs, and calves during the operation and then one cotton blanket over the entire body postoperatively. No other warming device was used. A core temperature below 36°C was considered hypothermia. Before performing spinal anesthesia, each patient received 10 ml kg⁻¹ h⁻¹ of lactated Ringer’s solution. The infusion rates were then reduced to 6 ml kg⁻¹ h⁻¹. Following the guidelines for asepsis and antisepsis, subarachnoid anesthesia was instituted at either the L3-4 or L4-5 interspaces. A volume of 3 ml of hyperbaric bupivacaine (Marcaine® Spinal Heavy 0.5%, AstraZeneca, Istanbul, Turkey) was injected using a 25 G Quincke spinal needle (Typo Healthcare, Gasport, UK).

The patients were randomized to one of two groups by sequentially numbered envelopes, which designated them to receive saline (group C, n = 30) or dexmedetomidine (group D, n = 30). An investigator who was not otherwise involved in the study prepared syringes containing saline or dexmedetomidine; thus, the study was double-blinded. Just after intrathecal injection, all drugs were infused intravenously. Dexmedetomidine (Precedex®, Meditera, Istanbul, Turkey) was diluted to a volume of 50 ml (4 µg ml⁻¹) and presented as coded syrings by an anesthesiologist. Group D was given an i.v. bolus of dexmedetomidine 1 µg kg⁻¹ administered by a syringe pump (Perfuser compact, Braun, Germany) over a 10-min period followed by an infusion of 0.4 µg kg⁻¹ h⁻¹ dexmedetomidine during the surgery. Group C received an equal volume of saline. The infusions were stopped at the completion of the closure of the skin. Supplemental oxygen (2 l min⁻¹) was delivered via a facemask during the operation. Motor block was assessed using a modified Bromage scale (0, no motor block; 1, hip blocked; 2, hip and knee blocked; 3, hip, knee, and, ankle blocked). Full motor recovery was assessed as 0 on the Bromage scale. Sensorial block was assessed by the pinprick test. The levels of motor and sensory blockade were assessed during the intraoperative period. The presence of shivering was assessed by a blinded observer after the completion of subarachnoid drug injection. Shivering was graded on a scale similar to that validated by Tsai and Chu: 0 = no shivering, 1 = piloerection or peripheral vasoconstriction but no visible shivering, 2 = muscular activity in only one muscle group, 3 = muscular activity in more than one muscle group but not generalized, and 4 = shivering involving the whole body. The incidence and severity of shivering were recorded at 5-min intervals during the operation and in the recovery room. If scores were three or greater at 15 minutes after spinal anesthesia, the prophylaxis was regarded as ineffective, and 25 mg pethidine was administered by i.v. Side effects, such as headache, allergy, hypotension, bradycardia, waist and back pain, sedation score, total spinal block, and difficulty in micturition, nausea and vomiting were recorded. If the patient’s heart rate fell below 50 bpm, 0.5 mg atropine was administered by i.v. Hypotension was defined as a decrease in the mean arterial pressure (MAP) of more than 20 % from baseline (baseline MAP was calculated from three measurements taken in the ward before surgery). Hypotension was treated with 10 mg ephedrine via i.v. bolus and then with further i.v. infusion of lactated Ringer’s solution as required. The quantity of ephedrine given in each group was recorded. If patients developed nausea and vomiting, 10 mg metoclopramide was administered through the i.v. Postoperatively, all patients were monitored, given oxygen via a facemask and were covered with one layer of drapes and one cotton blanket. The post-anesthesia care unit temperature was maintained at 25°C to 26°C and constant humidity. If shivering scores were greater than or equal to 3, 25 mg pethidine was administered through the i.v. The attending anesthesiologist also assessed the degree of sedation on a 5-point scale: 1 = fully awake and oriented, 2 = drowsy, 3 = eyes closed but open on command, 4 = eyes closed but open to mild physical stimulation, and 5 = eyes closed and unresponsive to mild physical stimulation.

SPSS 11.0 (SPSS Inc., Chicago, IL) was used to analyze all statistical data. Sample size estimation was based on our preliminary study to detect shivering in 15% of patients using the 2-sided t test with alpha = 0.05 and a power of

| Types of operation | Group (n = 30) | Control Group (n = 30) |
|--------------------|---------------|-----------------------|
| Varicose vein       | 8             | 9                     |
| Umbilical hernia    | 2             | 3                     |
| Arthroscopy         | 10            | 10                    |
| Bladder tumor       | 5             | 4                     |
| Ureterorenoscopy    | 5             | 4                     |

There were no significant differences among the groups.

Table 1 - Demographic and intraoperative variables of the subjects - medians and ranges.
80%. Quantitative variables were compared between groups using Student’s t-test or a Mann-Whitney U-test where appropriate. Within-group data for core temperature were analyzed by using repeated-measures analysis of variance followed by Bonferroni’s post-hoc testing. Within-group data for heart rate and mean arterial pressure were analyzed using a Friedman test. Chi-square analysis was used for comparison of categorical variables. The results are shown as median (range), mean (±SD), exact numbers or proportions are expressed as a percentage. \( p < 0.05 \) was considered statistically significant.

RESULTS

The two groups were similar regarding age, weight, height, duration of surgery, duration of motor block, and duration of sensorial block (Table 1). Hypothermia was observed in 21 patients (70%) in group D and in 20 patients (66.7 %) in group C \( (p = 0.781) \). The core temperature of patients was not different between the groups during the intraoperative or postoperative periods (Figure 1). Three patients (10%) in group D and 17 patients (56.7%) in group C experienced shivering \( (p = 0.001) \). One patient had Grade 1 and two patients had Grade 2 shivering in group D. The intensity of shivering was lower in group D than in group C \( (p = 0.001) \), and Grade 4 shivering was not noted in any patient in either group. Patients’ shivering scores are given in Table 2. There were no statistically significant differences for the mean onset times of shivering between groups, which were 10 (5-15) min in group D and 15 (5-45) min in group C \( (p = 0.207) \). However, there were statistically significant differences for sedation between groups, all patients in group D and six patients in group C were in levels 3-5 of sedation \( (p = 0.001) \). Mean arterial pressures and heart rates were lower in group D following the infusion of dexmedetomidine during the intra and postoperative periods (Figures 2 and 3). Although five patients in group C needed meperidine (25 mg, i.v.) to treat shivering, no patients in group D needed this treatment. Three patients in group D and one patient in group C were given 0.5 mg atropine. One patient in group D was given 10 mg ephedrine by i.v. during the operation. There were no statistically significant differences for adverse events between groups (Table 3). Two patients in group D and one patient in group C had nausea. Two patients in group D and one patient in group C had difficulty in micturition in the first 24 hours following spinal anesthesia. During the one-week follow-up interview, one patient in each group reported headache with equivocal characteristics of a postural puncture headache, both of which resolved with conservative management.

| Shivering score | Group D \( (n = 30) \) | Group C \( (n = 30) \) |
|-----------------|-------------------------|-------------------------|
| 0               | 27*                     | 13                      |
| 1               | 1                       | 7                       |
| 2               | 2                       | 5                       |
| 3               | 0                       | 5                       |
| 4               | 0                       | 0                       |

\*\( p = 0.001 \) (Chi-square test).

\*\( p = 0.001 \) compared with the other groups using the Chi-square test.

DISCUSSION

We found that dexmedetomidine infusion effectively decreased the incidence and severity of shivering related to regional anesthesia during elective minor surgeries. The exact mechanism of shivering during regional anesthesia has not been fully established. The possible mechanisms include cessation of central thermoregulation, internal redistribution of body heat, and heat loss to the environment.\(^2,11,12\) Redistribution of core temperature during regional anesthesia is typically restricted to the legs, and therefore core temperature decreases about half as much during regional anesthesia as during general anesthesia.\(^11\) Vasocostriction and shivering are restricted to the upper body during spinal anesthesia, as they are inhibited below the level of blockade through sympathetic and somatic neural block.\(^12\) In contrast to these changes, vasocostriction and shivering are restricted to the upper body during spinal anesthesia. The median incidence of shivering related to neuraxial anesthesia in the control groups of 21 studies is 55% (interquartile range of 40-64%).\(^1\) which is nearly similar to that of the control group in our study (63.4%). As shivering is a response to hypothermia, body temperature should be normally maintained within the normal limits of 36.5-37.5°C.\(^13\) Major risk
factors in regional anesthesia for hypothermia are aging, level of sensory block, and temperatures of the operating room and intravenous solutions. In our study, the temperature of the operating room was maintained at 21-22 °C, and all fluids and drugs were at room temperature during the surgery. Various drugs have been used to treat or prevent postoperative shivering. However, dexmedetomidine may be a good choice among them because of its dual effects of anti-shivering and sedation. Pharmacological therapies, such as pethidine, tramadol, physostigmine, clonidine, ketamine, and magnesium, have been used to prevent shivering. Although clonidine has been used safely and effectively to treat shivering, other drugs, such as urapidil, may not be appropriate because the incidence of hypotension is high during spinal anesthesia. Dexmedetomidine, on the other hand, is a short acting α2 mimetic with less hypotensive effect and an added a sedative effect. Meperidine, the most widely used agent to prevent shivering, may cause nausea and vomiting as well as respiratory depression during and after spinal anesthesia. Hypertensive and tachycardic effects of ketamine have also been reported. The search continues for drugs that sufficiently improve the tolerance of thermoregulation without simultaneously producing excessive sedation, respiratory depression, or hemodynamic instability. Dexmedetomidine is used for the sedation of mechanically ventilated patients in the intensive care unit. Thus, it has been rarely used for the prevention of vasoconstriction and shivering during spinal anesthesia.

Dexmedetomidine displays specific and selective α2-adrenoceptor agonism in the brain and spinal cord. The responses to activation of these receptors include decreased sympathetic tone with attenuation of the neuroendocrine and hemodynamic responses to anesthesia and surgery. Thus, dexmedetomidine can mediate both the beneficial and unwanted effects of shivering provoked by hypothermia, such as increased catecholamine concentrations, oxygen consumption, blood pressure, and heart rates.

Dexmedetomidine exerts its dual effects while avoiding vasoconstriction and increasing the level of the shivering threshold, but meperidine, only increases the shivering threshold in healthy volunteers. In contrast to our results, Coskuner et al. did not observe shivering with the same dose that we used in our study. Also, Elvan and colleagues reported that dexmedetomidine infusion during surgery was effective in the prevention of post-anesthetic shivering in patients undergoing elective abdominal hysterectomy. Bicer and colleagues found the incidence of shivering as 15% with dexmedetomidine and 55% with placebo following general anesthesia. Our results are similar to their study with the incidences being 10% and 56.7%, respectively. The lower incidence of shivering in the dexmedetomidine group may be related to the depression

Figure 2 - Mean Arterial Pressures. MAP: Mean Arterial Pressure, io: intraoperative, po: postoperative, min; minute, Intraoperative and postoperative mean arterial pressure. +<0.05 when two groups are compared.

Figure 3 - Heart Rates. io: intraoperative, po: postoperative, min; minute, Intraoperative and postoperative heart rate. *p<0.05 when two groups are compared, †p<0.05 compared with baseline value.
In our study, the mean arterial pressures were a21 Group C None of our patients had 00 , B, Uzun S, Karabulut E, Coskun F, Aypar U. 21 groups. Table 3 - been shown that objectives in using sedative agents is that the drug should the incidence of bradycardia was 10% in group D, one anesthesia. conclude that dexmedetomidine infusion as a good choice associated with spinal anesthesia during minor surgical procedures. The hemodynamic effects of dexmedetomidine are biphasic. When it is administered through an i.v., it causes hypotension and bradycardia until central sympathomimetic effect is achieved, and then it causes moderate decreases in MAP and HR.27,28 In our study, the mean arterial pressures were lower after the start of the infusion especially at 105 and 120 minutes during the surgery. HR was found to be significantly lower in the dexmedetomidine group when compared with the control group beginning from the 5th minute of infusion until the end of the blockade. Furthermore, while the incidence of bradycardia was 10% in group D, one patient developed bradycardia in group C. One of the main objectives in using sedative agents is that the drug should not cause respiratory depression. In previous studies, it has been shown that μ2-adrenergic agonists cause no or minimal respiratory depression.29-30 None of our patients had respiratory depression during the operation or in the recovery room. In conclusion, dexmedetomidine infusion in the periooperative period significantly reduced the shivering associated with spinal anesthesia during minor surgical procedures without any major adverse effects. We therefore conclude that dexmedetomidine infusion is a good choice for preventing shivering in patients undergoing spinal anesthesia.
