Keywords
microRNA-155-5p · Nuclear receptor subfamily 3 group C member 2 · Clear cell renal cell carcinoma · Malignant progression

Abstract
Background: The molecular heterogeneity of clear cell renal cell carcinoma (ccRCC) leads to a high mortality of the disease, which seriously threatens the life of patients. Therefore, this study explored the functional significance and mechanism of microRNA-155-5p and nuclear receptor subfamily 3 group C member 2 (NR3C2) in the regulation of ccRCC.

Methods: Expression levels of microRNA-155-5p and NR3C2 mRNA in ccRCC cells were analyzed by qRT-PCR, and the protein expression of NR3C2 in human ccRCC cells was measured by Western blot. Biological functions were determined through a series of in vitro experiments. The interaction between microRNA-155-5p and NR3C2 was tested by luciferase reporter gene assay. In addition, the effect of overexpressed or silenced microRNA-155-5p on cell phenotypes was evaluated in ccRCC cells.

Results: Experimental data suggested that overexpression or silencing of microRNA-155-5p in ccRCC could boost or suppress cancer cell proliferation and other malignant behaviors. Rescue experiments revealed that microRNA-155-5p facilitated the proliferation, migration, and invasion and suppressed the apoptosis of ccRCC by directly inhibiting the expression of NR3C2.

Conclusions: This is the first study to generate new insights into the role of microRNA-155-5p/NR3C2 interaction in promoting the process of ccRCC, and it is possible to bring a turning point for the treatment of ccRCC.

Introduction

As the second most common type of cancer diagnosed in the human urinary system, renal cell carcinoma (RCC) accounts for about 3% of all malignancies and is the main cause of death with the incidence increasing year by year [1–3]. As a major subtype of RCC, clear cell RCC (ccRCC) occupies 70–80% of RCC [4] and imposes a serious impact on life quality of human beings. Currently, surgical resection is still the main treatment for ccRCC, but there are still nearly 40% of patients with recurrence or distant metastasis after treatment. Despite notable advances in surgical treatment recently, ccRCC patients’ survival re-
mains unsatisfactory [5, 6]. Therefore, it is urgent to further understand the mechanism of ccRCC tumorigenesis and progression and to find more effective treatment methods for ccRCC patients.

As a class of small noncoding RNAs, microRNAs consist of 18–24 nucleotides and can negatively modulate their target genes through directly binding to the 3′ UTR of target genes [7], thus playing a critical regulatory part in physiological and pathological processes of the human body [8]. In recent years, with the deepening of research on the function of microRNA, it was confirmed that microRNA also plays a key part in the occurrence and progression of ccRCC. For example, Xie et al. [9] uncovered that microRNA-363 inhibits the proliferation, invasion, and migration of ccRCC cells via downregulating S1PR1. In addition, Liu et al. [10] also found that microRNA-935 facilitates the invasion and migration of ccRCC cells by targeting IREB2. However, several researchers unveiled that microRNA-155-5p on chromosome 21 regulates the progression of various cancers. For example, Chen et al. [11] confirmed that increased expression of microRNA-155-5p can boost apoptosis of hepatocellular carcinoma cells by downregulating CThrC1 while inhibiting cell cycle progression, cell proliferation, cell invasion, and cell migration. Ning Li [12] found that microRNA-155-5p can induce the metastasis of cervical cancer, and its regulatory function is realized through the inhibition of TP53INP1. However, the molecular regulation mechanism of microRNA-155-5p in ccRCC remains unclear and needs to be further explored.

In the current study, we observed whether microRNA-155-5p was differentially expressed in ccRCC cells and normal renal epithelial cells, as well as the effect of microRNA-155-5p on the phenotype of ccRCC cells through a series of functional experiments. Also, the downstream molecular regulatory mechanism of microRNA-155-5p in ccRCC was further explored. The results of this study will provide a theoretical basis for applying microRNA-155-5p as a potential molecular therapeutic target for patients with ccRCC.

Materials and Methods

Bioinformatics Analysis

The data of microRNA expression level (normal: 71, tumor: 545) and mRNA expression level (normal: 72, tumor: 539) of ccRCC were downloaded from TCGA database (https://portal.gdc.cancer.gov/) on November 29, 2019. A T test was applied to determine the expression of microRNA-155-5p in normal tissue and ccRCC tissue. Then, starBase (http://starbase.sysu.edu.cn/), TargetScan (http://www.targetscan.org/vert_72/), mirDIP (http://ophid.utoronto.ca/mirDIP/index.jsp#r), and miRDB (http://mirdb.org/) were employed to predict the downstream regulatory target genes of microRNA-155-5p. In addition, the R package “edgeR” was used to analyze the difference in the mRNA expression data between the normal group and the tumor group (log |FC| >1.5, FDR <0.05), and the results obtained were intersected with the differential mRNAs. Subsequently, the Pearson correlation analysis was applied to finally determine the target mRNA regulated by microRNA.

Cell Culture and Transfection

Human proximal renal tubular epithelial cell line HK2 (ATCC® CRL-2190) and human ccRCC cell lines 786-O (ATCC® CRL-1932), A498 (ATCC® HTB-44), ACHN (ATCC® HTB-1611), and Caki-1 (ATCC® HTB-46) were purchased from ATCC. The HK2 cell line was cultured in Defined Keratinocyte SFM ( Gibco, BRL, MT, USA). The 786-O cell line was cultured in RPMI-1640 medium. A498 and ACHN cell lines were cultured in DMEM. The Caki-1 cell line was cultured in McCoy’s 5A medium. All media contained 10% FBS (Gibco) and 1% penicillin and streptomycin (Invitrogen, Waltham, MA, USA). All cells were cultured in a 37°C humid incubator with 5% CO₂.

MicroRNA-155-5p mimic, microRNA-155-5p inhibitor, sh-nuclear receptor subfamily 3 group C member 2 (NR3C2), and their corresponding negative controls (NC-mimic, NC-inhibitor, and sh-NC) were ordered from RiboBio (Guangzhou, China). The transfection was performed using Lipofectamine 2000 reagent (Invitrogen) according to the manufacturer’s instructions.

RNA Extraction and qRT-PCR

Total RNA was isolated from 5 cell lines using TRIzol reagent (Invitrogen) for cDNA synthesis. Quantitative determination of mature microRNA and mRNA (microRNA-155-5p [accession No. AP000223] and NR3C2 [accession No. AB209056]) was performed using TaqMan microRNA (Applied Biosystems Inc., Foster City, CA, USA). U6 and GAPDH were applied as endogenous controls. qRT-PCR was performed using the QuantStudio 7 PCR system and Taqman universal PCR premix. The expression of microRNA-155-5p or NR3C2 was standardized. The primers used are shown in Table 1.

Western Blot

After 72 h, cells were collected and lysed using NP-40 (Thermo Scientific). The Bicinchoninic Acid Protein Assay (Thermo Scientific) was used to measure the protein concentration. NuPAGE 4–12% Bis–Tris protein gel (Invitrogen) for cDNA synthesis. Quantitative determination of mature microRNA and mRNA (microRNA-155-5p [accession No. AP000223] and NR3C2 [accession No. AB209056]) was performed using TaqMan microRNA (Applied Biosystems Inc., Foster City, CA, USA). U6 and GAPDH were applied as endogenous controls. qRT-PCR was performed using the QuantStudio 7 PCR system and Taqman universal PCR premix. The expression of microRNA-155-5p or NR3C2 was standardized. The primers used are shown in Table 1.

CCK-8

The CCK8 cell proliferation assay kit (Dojindo Laboratories, Kumamoto, Japan) was employed to determine the proliferative
capacity of the transfected cells. The 100 μL suspension with transfected cells was inoculated into a 96-well plate. At specific time point of 0, 24, 48, and 72 h, 10 μL of CCK8 reagent was added to each well (be careful to avoid bubbles). 2 h after reagent addition, the absorbance was measured at 450 nm with a microplate reader.

**Scratch Healing Assay**

Before inoculating cells, a marker pen was used to draw a horizontal line on the back of the 6-well plate (to facilitate the positioning of the same field of vision during photographing). Cells were transferred and then seeded into 6-well plates. When cells covered the bottom of the hole, monolayer cells were scraped with a sterile 10 μL micropipette. The cell fragments generated by scratching were removed, and then, serum-free medium was added. The wound areas of the cells were observed and photographed at 0 h and 48 h. Cell migration rate = \[1 - \frac{\text{wound area at } T_{t}}{\text{wound area at } T_{0}}\] × 100%. \(T_{0}\) represented the time immediately after scratching, and \(T_{t}\) represented the time 48 h after scratching.

**Transwell Invasion Assay**

Fifty microliter Matrigel (BD Biosciences, San Jose, CA, USA) was coated on the upper layer of the insert at 4°C. Cells were incubated for 12 h without serum and were then washed and seeded into the upper chamber with serum-free bovine serum albumin (Invitrogen). 500 μL DMEM high-glucose medium with 20% FBS was placed in the lower chamber. Twenty-four hour later, the Matrigel and cells in the upper chamber were removed with a cotton swab. The remaining cells were fixed with 4% paraformaldehyde and stained with 0.1% crystal violet. The average cell number was counted in 5 randomly selected fields under an upright microscope.

**Cell Apoptosis Assay**

Cells were collected 72 h after transfection. The cells were washed with cold PBS, blown, and beat with a pipette to be fully resuspended in a binding buffer. Under dark conditions, the cells were stained with Annexin V-FITC and propidium iodide. Fifteen minutes later, the cells were washed and analyzed using BD FACSVerse (BD Pharmingen).

**Dual-Luciferase Assay**

To evaluate the mRNA that may be targeted by microRNA-155-5p, the bioinformatics database was used to search for genes that can bind to microRNA-155-5p. Luciferase reporter vectors were constructed by ligation with a custom NR3C2 oligonucleotide containing the putative binding sites and the corresponding nontarget/mutation sites and were then inserted into pmiR-GLO reporting vector (Promega, Madison, WI, USA). HEK-293T cells treated with microRNA-155-5p mimic and negative controls were co-transfected with either NR3C2 wild type or NR3C2 mutant. Luciferase activity was detected using the Dual-Luciferase Reporter Gene at 48 h after transfection. The relative activity was calculated by normalized renilla luciferase.

**Statistical Analysis**

All assays were conducted with 3 biological replicates and were expressed to be mean ± standard deviation. GraphPad Prism6 was applied for statistical analysis using Student’s t test. \(p < 0.05\) was considered significant.

**Results**

**MicroRNA-155-5p Is Highly Expressed in ccRCC**

It was reported that microRNA-155-5p expression is enhanced in various tumors and promotes malignant progression of cancer cells [12–14]. Therefore, based on the data of TCGA, we deduced that microRNA-155-5p expression was also upregulated in ccRCC tissue (Fig. 1a). Compared to normal renal epithelial cells (HK2), four ccRCC cell lines had significantly elevated microRNA-155-5P expression, which further confirmed the upregulation of microRNA-155-5p in ccRCC (Fig. 1b). Through these experimental results, we fully proved that microRNA-155-5p was highly expressed in ccRCC.

**MicroRNA-155-5p Promotes Malignant Progression of ccRCC**

To further evaluate the regulatory function of microRNA-155-5p on ccRCC, we first transfected microRNA-155-5p-inhibitor and NC-inhibitor (negative control) into...
786-O cells with relatively high expression of microRNA-155-5p. Meanwhile, Caki-1 cells with relatively low microRNA-155-5p expression were treated with the microRNA-155-5p mimic for overexpressing microRNA-155-5p. In addition, Caki-1 cells were transfected with the NC-mimic as the negative control. qRT-PCR confirmed that the transfection efficiency of each treatment group was in line with expectations, indicating that the transfected cells could be used for subsequent experiments (Fig. 2a). Then, the effects of microRNA-155-5p silencing and microRNA-155-5p overexpression on the proliferation, migration, invasion, and apoptosis of ccRCC cells were detected by cell biological functional assays. CCK-8 results expressed that silenced microRNA-155-5p notably suppressed the proliferation of 786-O cells, while overexpressed microRNA-155-5p prominently boosted the proliferation of Caki-1 cells (Fig. 2b). Meanwhile, scratch healing and Transwell assays suggested that silence of microRNA-155-5p reduced the migration and invasion of 786-O cells while overexpression of microRNA-155-5p enhanced the migration and invasion of Caki-1 cells (Fig. 2c–d). In addition, silenced microRNA-155-5p promoted the apoptosis of 786-O cells, while overexpressed microRNA-155-5p decreased the apoptosis of Caki-1 cells in the cell apoptosis assay (Fig. 2e). These results strongly indicated that microRNA-155-5p could induce malignant progression of ccRCC.

NR3C2 Is a Direct Target of microRNA-155-5p

In order to explore the downstream molecular mechanism of microRNA-155-5p, we next identified potential targets to clarify the functional role of microRNA-155-5p. Target predictions in silico was carried out by adopting 4 different algorithms – starBase, TargetScan, miRDB, and mirDIP. starBase provides information on the interaction between microRNAs and various RNA molecules, and it predicted 2,222 target genes for microRNA-155-5p. Customized TargetScan predicted 556 target genes for microRNA-155-5p. miRDB contains selected and possible microRNA targets, and it predicted 701 target genes for microRNA-155-5p. mirDIP contains the most comprehensive human microRNA target genes, and it predicted 1,447 target genes for microRNA-155-5p. To increase the rigor of the prediction, we limited potential targets to the four algorithms. Finally, a total of 215 target genes were obtained (Fig. 3A). Then, differential analysis was further performed on the data set of mRNA expression levels of ccRCC in TCGA, finding 2,468 mRNAs were upregulated and 1,165 mRNAs were downregulated in tumor tissue (Fig. 3B). Then, based on the negative regulatory mechanism of microRNA-mRNA in ceRNA, 1,165 downregulated mRNAs were intersected with 215 mRNAs predicted by the database, and finally 5 target mRNAs that had binding sites with microRNA-155-5p were gained (Fig. 3C). Correlation analysis revealed that NR3C2 had the highest negative correlation with microRNA-155-5p (Fig. 3D). Meanwhile, survival analysis of patients with ccRCC showed that low expression of NR3C2 was markedly detrimental to the prognosis of patients (Fig. 3E). Therefore, we finally chose NR3C2 as the study object. The specific expression of NR3C2 in tumor tissue in
TCGA database is shown in Figure 3F. To confirm that NR3C2 is the downstream target of microRNA-155-5p, the expression levels of HK2 and ccRCC cell lines were tested by qRT-PCR and Western blot. The results indicated that the NR3C2 expression level in ccRCC cells was prominently lower than that in normal renal epithelial cells (Fig. 3G). In addition, the targeting between microRNA-155-5p and NR3C2 was detected by the dual-luciferase assay. The results suggested that microRNA-155-5p prominently reduced the luciferase activity of the NR3C2-WT reporter gene. This indicated that microRNA-155-5p could target NR3C2 (Fig. 3H). Finally, we also observed the expression of NR3C2 in 786-O cells with silenced microRNA-155-5p and Caki-1 cells with overexpressed microRNA-155-5p, finding that silenced microRNA-155-5p notably upregulated NR3C2 in ccRCC (Fig. 3I). However, overexpressed microRNA-155-5p remarkably downregulated NR3C2 in ccRCC (Fig. 3I). The above experimental results proved that NR3C2 was the target gene of microRNA-155-5p, and microRNA-155-5p could negatively regulate the expression of NR3C2.

**MicroRNA-155-5p Restrains ccRCC Malignant Progression by Targeting NR3C2**

To determine whether microRNA-155-5p modulates the progression of ccRCC by targeting NR3C2, 786-O cells were transfected with the following vector groups: NC-inhibitor + sh-NC (negative control), microRNA-155-5p-inhibitor + sh-NC, and microRNA-155-5p-inhibitor + sh-NR3C2. The mRNA and protein expression levels of NR3C2 in 786-O cells of the 3 groups were detected by qRT-PCR and Western blot. The results suggested that sh-NR3C2 reversed the effects of microRNA-155-5p-inhibitor on NR3C2 mRNA and protein in ccRCC cells (Fig. 4A). After that, the proliferation, migration, invasion, and apoptosis of 786-O cells in 3 groups were observed by cell biological functional experiments. It was found that the transfection of sh-NR3C2 markedly overturned the inhibitory effects of the microRNA-155-5p-inhibitor on the proliferation of ccRCC cells (Fig. 4B).
Fig. 3. NR3C2 is the target gene of microRNA-155-5p. A Venn diagram of target genes of microRNA-155-5p. B Volcano map of differential genes in the ccRCC mRNA data set in TCGA database between the normal group and the tumor group. Red and green dots represent upregulated and downregulated mRNA expression in ccRCC tissue, respectively. C Venn diagram of downregulated genes in ccRCC and predicted target genes of microRNA-155-5p. D Pearson correlation heat map of microRNA-155-5p and its target genes. E Effect of NR3C2 expression on prognosis of ccRCC patients. F NR3C2 expression in TCGA database is downregulated in the tumor group. G Expression of NR3C2 mRNA and protein in HK2 and ccRCC cell lines. H Binding of microRNA-155-5p and NR3C2 detected by the dual-luciferase assay. I, J Effects of silencing or overexpressing microRNA-155-5p on NR3C2 expression in ccRCC cells.* denotes p < 0.05. NC, negative control.
Knockdown of NR3C2 reversed the inhibitory effect of the microRNA-155-5p-inhibitor on ccRCC cell migration (Fig. 4C). Similarly, inhibition of microRNA-155-5p significantly reduced the number of invaded cells, while knockdown of NR3C2 reversed the inhibitory effect of microRNA-155-5p-inhibitor on ccRCC cell invasion (Fig. 4D). In addition, inhibition of microRNA-155-5p remarkably increased the apoptosis rate, while NR3C2 knockdown overturned the promoting effect of microRNA-155-5p-inhibitor on ccRCC cell apoptosis (Fig. 4E). These findings indicated that microRNA-155-5p could suppress the malignant progression of ccRCC by targeting NR3C2.

**Discussion**

More and more studies confirmed that microRNAs are often dysregulated in ccRCC and play a part in promoting or inhibiting the progression of ccRCC. For instance, Chen et al. [15] proved that the expression level of microRNA-645 is notably upregulated in ccRCC tissue compared to adjacent tissue, and downregulation of microRNA-645 can constrain the malignant properties of ccRCC cells and promote cell apoptosis. Maolakuerban et al. [16] also uncovered that microRNA-200C-3p is under-expressed in ccRCC tissue, and microRNA-200C-3p can suppress the proliferation, invasion, and migration of ccRCC.
ccRCC cells. In this study, it was confirmed that microRNA-155-5p was also upregulated in ccRCC, and it was further found through cell biological functional experiments that silenced microRNA-155-5p inhibited the proliferation, migration, and invasion of ccRCC cells while induced cell apoptosis. However, overexpression of microRNA-155-5p could boost the phenotypes of ccRCC cells while restraining cell apoptosis. These results strongly suggested that microRNA-155-5p is an oncogenic factor in ccRCC and can induce malignant progression of ccRCC cells.

NR3C2 is defined as a gene for the mineralocorticoid receptor (MR), located on human chromosome 4q31.1-31.2, and encodes the MR. The MR is expressed in a variety of tissues, including the colon, kidney, heart, sweat glands, etc. In epithelial tissue, MR activation results in sodium reabsorption by regulating the expression of ions and water-related transport proteins, thereby increasing extracellular volume to maintain a normal salt concentration in vivo [17]. However, recent studies found that NR3C2 is not only associated with memory loss [18], pseudohypoaldosteronism [19], and hypertension [20], it also plays a critical regulatory part in the development of various cancers through inhibition by a variety of microRNAs. For example, Zhao et al. [21] confirmed that microRNA-1204 can boost glioblastoma proliferation and reduce cell apoptosis by targeting NR3C2. Guo et al. [22] demonstrated that microRNA-454 plays an oncogenic role in oral squamous-cell carcinoma by targeting NR3C2 expression. However, in the present study, the downstream targets of microRNA-155-5p were mined by bioinformatics prediction, revealing that there is a binding relationship between NR3C2 and microRNA-155-5p, which presented a negative correlation in ccRCC tissues. Subsequently, it was confirmed that NR3C2 was indeed under-expressed in ccRCC cells. Then, the dual-luciferase assay also verified that microRNA-155-5p and NR3C2 could bind to each other. Further studies expressed that silenced microRNA-155-5p could lead to the upregulation of ccRCC mRNA and protein expression, while over-expression of microRNA-155-5p could lead to the opposite result. Finally, the rescue experiments indicated that downregulation of NR3C2 reversed the inhibitory effects of silenced microRNA-155-5p on proliferation, migration, and invasion of ccRCC cells, as well as the promoting effect on cell apoptosis. This suggested that microRNA-155-5p could promote the malignant progression of ccRCC cells by targeting NR3C2.

Collectively, in this study, we uncovered that microRNA-155-5p was an oncogenic factor of ccRCC and induced malignant progression of ccRCC cells. The tumor-promoting function of microRNA-155-5p in ccRCC was realized through inhibition of the expression of NR3C2. This study lays a certain foundation for microRNA-155-5p as a potential therapeutic target in ccRCC patients. However, there are still shortcomings in this study. For example, the differential expression of microRNA-155-5p was not verified in clinical tissue and the regulatory function of microRNA-155-5p on the progression of ccRCC was not studied in vivo. These need to be further explored in subsequent studies.

Statement of Ethics

An ethics statement was not required for this study type as no human or animal subjects or materials were used.

Conflict of Interest Statement

The authors have no conflicts of interest to declare.

Funding Sources

This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

Author Contributions
