Abstract

We begin by giving correct expressions for the short-time action; following the work of one of us and Makri–Miller. We use these estimates to derive a correct expression modulo $\Delta t^2$ for the quantum propagator and we show that the quantum potential is negligible modulo $\Delta t^2$ for a point source. We finally prove that this implies that the quantum motion is classical for very short times.

Keywords: generating function, short-time action, quantum potential, Bohmian trajectories

1 Introduction

Explicit approximate expressions for the short-time action play an essential role in various aspects of quantum mechanics (for instance the Feynman path integral, or semi-classical mechanics), and so does the associated Van Vleck determinant. Unfortunately, as already observed by Makri and Miller [15] [16], the literature seems to be dominated by formulas which are wrong

*Financed by the Austrian Research Agency FWF (Projektnummer P20442-N13).
even to the first order of approximation! Using the calculations of Makri and Miller, which were independently derived by one of us in [3] using a slightly different method, we show that the correct approximations lead to precise estimates for the short-time Bohmian quantum trajectories for an initially sharply located particle. We will see that these trajectories are classical to the second order in time, due to the vanishing of the quantum potential for small time intervals.

In this paper we sidestep the philosophical and ontological debate around the “reality” of Bohm’s trajectories and rather focus on the mathematical issues.

2 Bohmian trajectories

Consider a time-dependent Hamiltonian function

\[ H(x, p, t) = \sum_{j=1}^{n} \frac{p_j^2}{2m_j} + U(x, t) \]  

and the corresponding quantum operator

\[ \hat{H}(x, -i\hbar \nabla_x, t) = \sum_{j=1}^{n} \frac{-\hbar^2 \partial^2}{2m_j \partial x_j^2} + U(x, t). \]

The associated Schrödinger equation is

\[ i\hbar \frac{\partial \Psi}{\partial t} = \hat{H}(x, -i\hbar \nabla_x, t) \Psi, \quad \Psi(x, 0) = \Psi_0(x). \]

Let us write \( \Psi \) in polar form \( Re^{i\Phi/\hbar} \); here \( R = R(x, t) \geq 0 \) and \( \Phi = S(x, t) \) are real functions. On inserting \( Re^{iS/\hbar} \) into Schrödinger’s equation and separating real and imaginary parts, one sees that the functions \( R \) and \( S \) satisfy, at the points \((x, t)\) where \( R(x, t) > 0 \), the coupled system of non-linear partial differential equations

\[ \frac{\partial S}{\partial t} + \sum_{j=1}^{n} \frac{1}{2m_j} \left( \frac{\partial S}{\partial x_j} \right)^2 + U(x, t) - \sum_{j=1}^{n} \frac{\hbar^2}{2m_j R} \frac{\partial^2 R}{\partial x_j^2} = 0 \]

\[ \frac{\partial R^2}{\partial t} + \sum_{j=1}^{n} \frac{1}{m_j} \frac{\partial}{\partial x_j} \left( R^2 \frac{\partial \Phi}{\partial x_j} \right) = 0. \]
The crucial step now consists in recognizing the first equation as a Hamilton–Jacobi equation, and the second as a continuity equation. In fact, introducing the quantum potential
\[ Q^\Psi = -\sum_{j=1}^{n} \frac{\hbar^2}{2m_j} \frac{\partial^2 R}{\partial x_j^2} \] (6)
(Bohm and Hiley [11]) and the velocity field
\[ v^\Psi(x, t) = \left( \frac{1}{m_1} \frac{\partial \Phi}{\partial x_1}, \ldots, \frac{1}{m_n} \frac{\partial \Phi}{\partial x_n} \right) \] (7)
the equations (4) and (5) become
\[ \frac{\partial \Phi}{\partial t} + H(x, \nabla_x \Phi, t) + Q^\Psi(x, t) = 0 \] (8)
\[ \frac{\partial \rho}{\partial t} + \text{div}(\rho v^\Psi) = 0 \ , \ \rho = R^2 \] (9)

The main postulate of the Bohmian theory of motion is that particles follow quantum trajectories, and that these trajectories are the solutions of the differential equations
\[ \dot{x}^\Psi_j = \frac{\hbar}{m_j} \text{Im} \frac{1}{\Psi} \frac{\partial \Psi}{\partial x_j}. \] (10)

The phase space interpretation is that the Bohmian trajectories are determined by the equations
\[ \dot{x}^\Psi_j = \frac{1}{m_j} p^\Psi_j \ , \ \dot{p}^\Psi_j = -\frac{\partial U}{\partial x_j}(x^\Psi, t) - \frac{\partial Q^\Psi}{\partial x_j}(x^\Psi, t). \] (11)

It is immediate to check that these are just Hamilton’s equations for the Hamiltonian function
\[ H^\Psi(x, p, t) = \sum_{j=1}^{n} \frac{p_j^2}{2m_j} + U(x, t) + Q^\Psi(x, t) \] (12)
which can be viewed as a perturbation of the original Hamiltonian \( H \) by the quantum potential \( Q^\Psi \) (see Holland [13, 14] for a detailed study of quantum trajectories in the context of Hamiltonian mechanics).

The Bohmian equations of motion are \textit{a priori} only defined when \( R \neq 0 \) (that is, outside the nodes of the wavefunction); this will be the case in our constructions since for sufficiently small times this condition will be satisfied by continuity if we assume that it is case at the initial time.

An important feature of the quantum trajectories is that they cannot cross; thus there will be no conjugate points like those that complicate the usual Hamiltonian dynamics.
## 3 The Short-Time Propagator

The solution $\Psi$ of Schrödinger’s equation (3) can be written

$$\Psi(x, t) = \int K(x, x_0; t)\Psi_0(x_0)dx_0$$

where the kernel $K$ is the “quantum propagator”:

$$K(x, x_0; t) = \langle x|\exp(-i\hat{H}t/\hbar)|x_0\rangle.$$  

Schrödinger’s equation (3) is then equivalent to

$$i\hbar \frac{\partial K}{\partial t} = \hat{H}(x, -i\hbar \nabla_x, t)K, \quad K(x, x_0; 0) = \delta(x - x_0)$$  

where $\delta$ is the Dirac distribution. Physically this equation describes an isotropic source of point-like particle emanating from the point $x_0$ at initial time $t_0 = 0$. We want to find an asymptotic formula for $K$ for short time intervals $\Delta t$. Referring to the usual literature, such approximations are given by expressions of the type

$$K(x, x_0; \Delta t) = \left(\frac{1}{2\pi i\hbar}\right)^{n/2} \sqrt{\rho(x, x_0; \Delta t)} \exp\left(\frac{i}{\hbar} S(x, x_0; \Delta t)\right)$$

where $S(x, x_0; \Delta t)$ is the action along the classical trajectory from $x_0$ to $x$ in time $\Delta t$ and

$$\rho(x, x_0; \Delta t) = \det \left(-\frac{\partial^2 S(x, x_0; \Delta t)}{\partial x_j \partial x_k}\right)_{1 \leq j, k \leq n}$$

is the corresponding Van Vleck determinant. It is then common practice (especially in the Feynman path integral literature) to use the following “midpoint approximation” for the generating function $S$:

$$S(x, x_0; \Delta t) \approx \sum_{j=1}^{n} \frac{m_j}{2\Delta t}(x_j - x_0)^2 - \frac{1}{2}(U(x, t_0) + U(x_0, t_0))\Delta t$$  

or, worse,

$$S(x, x_0; t, t_0) \approx \sum_{j=1}^{n} \frac{m_j}{2\Delta t}(x_j - x_0)^2 - (U(\frac{1}{2}(x + x_0), t_0))\Delta t$$  

However, as already pointed out by Makri and Miller [15, 16], these “approximations” are wrong; they fail to be correct even to first order in $\Delta t$! In fact,
Makri and Miller, and one of us [3] have shown independently, and using
different methods, that the correct asymptotic expression for the generating
function is given by

\[ S(x, x_0; \Delta t) = \sum_{j=1}^{n} \frac{m_j}{2\Delta t} (x_j - x_0)^2 - \bar{U}(x, x_0) \Delta t + O(\Delta t^2) \] (16)

where \( \bar{U}(x, x_0) \) is the average value of the potential over the straight line
joining \( x_0 \) at time \( t_0 \) to \( x \) at time \( t \) with constant velocity:

\[ \bar{U}(x, x_0) = \int_0^1 U(\lambda x + (1 - \lambda)x_0, 0) d\lambda. \] (17)

For instance when

\[ H(x, p) = \frac{1}{2m} (p^2 + m^2 \omega^2 x^2) \]

is the one-dimensional harmonic oscillator formula (16) yields the correct
expansion

\[ S(x, x_0; t) = \frac{m}{2\Delta t} (x - x_0)^2 - \frac{m \omega^2}{6} (x^2 + xx_0 + x_0) \Delta t + O(\Delta t^2); \] (18)

the latter can of course be deduced directly from the exact value

\[ S(x, x_0; t, t_0) = \frac{m \omega}{2 \sin \omega \Delta t} ((x^2 + x_0) \cos \omega \Delta t - 2xx_0) \] (19)

by expanding \( \sin \omega \Delta t \) and \( \cos \omega \Delta t \) for \( \Delta t \to 0 \). This correct expression is
of course totally different from the erroneous approximations obtained by
using the “rules” (14) or (15).

Introducing the following notation,

\[ \tilde{S}(x, x_0; \Delta t) = \sum_{j=1}^{n} m_j \frac{(x_j - x_0)^2}{2\Delta t} - \bar{U}(x, x_0) \Delta t, \] (20)

leads us to the Makri and Miller approximation (formula (17c) in [15]) for
the short-time propagator:

\[ K(x, x_0; \Delta t) = \left( \frac{1}{2\pi i \hbar} \right)^{n/2} \sqrt{\rho(x, x_0; \Delta t)} \exp \left( \frac{i}{\hbar} \tilde{S}(x, x_0; \Delta t) \right) + O(\Delta t^2) \] (21)
where
\[ \rho(x, x_0; \Delta t) = \text{det} \left( -\frac{\partial^2 \tilde{S}(x, x_0; \Delta t)}{\partial x_j \partial x_k} \right)_{1 \leq j, k \leq n}. \]

It turns out that this formula can be somewhat improved. The Van Vleck determinant \( \rho(x, x_0; \Delta t) \) is explicitly given, taking formula (20) into account, by
\[ \rho(x, x_0; \Delta t) = \text{det} \left( -\frac{1}{\Delta t} M - \tilde{U}''_{x,x_0}(x, x_0) \Delta t \right) \]
where \( M \) is the mass matrix (the diagonal matrix with positive entries the masses \( m_j \)) and
\[ \tilde{U}''_{x,x_0} = \left( -\frac{\partial^2 \tilde{U}(x, x_0)}{\partial x_j \partial x_k} \right)_{1 \leq j, k \leq n}. \]

Writing
\[ \left( -\frac{1}{\Delta t} M - \tilde{U}''_{x,x_0}(x, x_0) \Delta t \right) = -\frac{1}{\Delta t} M [I_{n \times n} - M^{-1} \tilde{U}''_{x,x_0}(x, x_0) \Delta t^2] \]
\[ = -\frac{1}{\Delta t} M [I_{n \times n} + \mathcal{O}(\Delta t^2)], \]
we have by taking the determinant of both sides
\[ \rho(x, x_0; \Delta t) = \frac{m_1 \cdots m_n}{(\Delta t)^n} \text{det} \left( I_{n \times n} + \mathcal{O}(\Delta t^2) \right). \]

Noting that \( \text{det} \left( I_{n \times n} + \mathcal{O}(\Delta t^2) \right) = 1 + \mathcal{O}(\Delta t^2) \), we thus have
\[ \rho(x, x_0; \Delta t) = \frac{m_1 \cdots m_n}{(\Delta t)^n} (1 + \mathcal{O}(\Delta t^2)). \tag{22} \]

Writing
\[ \tilde{\rho}(\Delta t) = \frac{m_1 \cdots m_n}{(\Delta t)^n} \tag{23} \]
which is just the Van Vleck density for the free particle Hamiltonian. We thus have
\[ \rho(x, x_0; \Delta t) = \tilde{\rho}(\Delta t) + \mathcal{O}(\Delta t^2) \tag{24} \]
and hence we can rewrite formula (21) as
\[ K(x, x_0; \Delta t) = \left( \frac{1}{2\pi i \hbar} \right)^{n/2} \sqrt{\tilde{\rho}(\Delta t)} \exp \left( \frac{i}{\hbar} \tilde{S}(x, x_0; \Delta t) \right) + \mathcal{O}(\Delta t^2). \tag{25} \]

We will see below that this formula allows an easy study of the quantum potential for \( K \).
4 Short-Time Bohmian Trajectories

Let us determine the quantum potential \( Q \) corresponding to the propagator \( K = K(x, x_0; t) \) using the asymptotic formulas above. Recall that it describes an isotropic source of point-like particle emanating from the point \( x_0 \) at initial time \( t_0 = 0 \). We have, by definition,

\[
Q = -\sum_{j=1}^{n} \frac{\hbar^2}{2m_j \sqrt{\rho}} \frac{\partial^2 \sqrt{\rho}}{\partial x_j^2}
\]

which we can rewrite

\[
Q = -\frac{\hbar^2 M^{-1}}{2} \nabla_x \cdot \nabla_x \sqrt{\rho}
\]

where \( M \) is the mass matrix defined above. We have, using (24),

\[
\sqrt{\rho} = \sqrt{\tilde{\rho}(\Delta t)(1 + O(\Delta t^2))}
\]

and hence

\[
\frac{\partial^2 \sqrt{\rho}}{\partial x_j^2} = O((\Delta t)^2)).
\]

From this it follows that the quantum potential associated with the propagator satisfies

\[
Q(x, x_0; \Delta t) = O((\Delta t)^2).
\]

The discussion above suggests that the quantum trajectory of a sharply located particle should be identical with the classical (Hamiltonian) trajectory for short times. Let us show this is indeed the case. If we want to monitor the motion of a single, we have of course to specify its initial momentum which gives its direction of propagation at time \( t_0 = 0 \); we set

\[
p(0) = p_0.
\]

In view of formula (10), the trajectory in position space is obtained by solving the system of differential equations

\[
\dot{x} = \hbar \text{Im} \frac{M^{-1} \nabla_x K}{K}, \quad x(0) = x_0.
\]

Replacing \( K \) with its approximation

\[
\tilde{K}(x, x_0; \Delta t) = \left( \frac{1}{2\pi i \hbar} \right)^{n/2} \sqrt{\rho(\Delta t)} \exp \left( \frac{i}{\hbar} \bar{S}(x, x_0; \Delta t) \right)
\]
we have, since $K - \tilde{K} = O(\Delta t^2)$ in view of (25),
\[
\dot{x} = \hbar \text{Im} \frac{M^{-1} \nabla_x \tilde{K}}{K} + O(\Delta t^2).
\]
A straightforward calculation, using the expression (20) for the approximate action $\tilde{S}(x, x_0; \Delta t)$, leads to (cf. the proof of Lemma 248 in [3]) the relation
\[
\dot{x}(\Delta t) = \frac{x(\Delta t) - x_0}{\Delta t} - M^{-1} \nabla_x \tilde{U}(x(\Delta t), x_0) \Delta t + O(\Delta t^2).
\] (29)
This equation is singular at time $t = 0$ hence the initial condition $x(0) = x_0$ is not sufficient for finding a unique solution; this is of course consistent with the fact that (29) describes an arbitrary particle emanating from $x_0$; to single out one quantum trajectory we have to use the additional condition (27) giving the direction of the particle at time $t = 0$ (see the discussion in Holland [12], §6.9). We thus have
\[
x(\Delta t) = x_0 + M^{-1} p_0 \Delta t + O(\Delta t^2);
\]
in particular $x(\Delta t) = x_0 + O(\Delta t)$ and hence, by continuity,
\[
\nabla_x \tilde{U}(x(\Delta t), x_0) = \nabla_x \tilde{U}(x_0, x_0) + O(\Delta t).
\]
Let us calculate $\nabla_x \tilde{U}(x_0, x_0)$. We have, taking definition (17) into account,
\[
\nabla_x \tilde{U}(x, x_0) = \int_0^1 \lambda \nabla_x U(\lambda x + (1 - \lambda)x_0, 0) d\lambda
\]
and hence
\[
\nabla_x \tilde{U}(x_0, x_0) = \int_0^1 \lambda \nabla_x U(x_0, 0) d\lambda = \frac{1}{2} \nabla_x U(x_0, 0).
\]
We can thus rewrite equation (29) as
\[
\dot{x}(\Delta t) = \frac{x(\Delta t) - x_0}{\Delta t} - \frac{1}{2} M^{-1} \nabla_x \tilde{U}(x_0, 0) \Delta t + O(\Delta t^2).
\]
Let us now differentiate both sides of this equation with respect to $\Delta t$:
\[
\ddot{x}(t) = \frac{x(t) - x_0}{(\Delta t)^2} + \frac{\dot{x}(t)}{\Delta t} - \frac{1}{2} M^{-1} \nabla_x \tilde{U}(x_0, 0) + O(\Delta t) \quad (30)
\]
that is, replacing $\dot{x}(\Delta t)$ by the value given by (29),
\[
\dot{p}(t) = M \ddot{x}(t) = -\nabla_x U(x_0, 0) + O(\Delta t). \quad (31)
\]
Solving this equation we get

\[ p(t) = p_0 - \nabla_x U(x_0, 0) \Delta t + O(\Delta t^2). \] (32)

Summarizing, the solutions of the Hamilton equations are given by

\[ x(\Delta t) = x_0 + \frac{p_0}{m} \Delta t + O(\Delta t^2) \] (33)
\[ p(\Delta t) = p_0 - \nabla_x U(x_0, 0) \Delta t + O(\Delta t^2). \] (34)

These equations are, up to the error terms \( O(\Delta t^2) \) the equations of motion of a classical particle moving under the influence of the potential \( U \); there is no trace of the quantum potential, which is being absorbed by the terms \( O(\Delta t^2) \). The motion is thus identical with the classical motion on time scales of order \( O(\Delta t^2) \).

5 Conclusion

This result puts Bohm’s original perception, which led him to the causal interpretation, on a firm mathematical footing. He writes [11]

Indeed it had long been known that when one makes a certain approximation (WKB) Schrödinger’s equation becomes equivalent to the classical Hamilton–Jacobi theory. At a certain point I asked myself: What would happen, in the demonstration of this equivalence, if we did not make this approximation? I saw immediately that there would be an additional potential, representing a kind of force, that would be acting on the particle.

The source of this “force” was the quantum potential. In our approach we see that while any classical potential acts immediately, the quantum potential potential does not. From this fact two consequences of our follow.

Firstly, it gives a rigorous treatment of the “watched pot” effect. If we keep observing a particle that, if unwatched, would make a transition from one quantum state to another, will no longer make that transition. The unwatched transition occurs when the quantum potential grows to produce the transition. Continuously observing the particle does not allow the quantum potential to develop so the transition does not take place. For details see section 6.9 in Bohm and Hiley [1].

Secondly, in the situation when the quantum potential decreases continuously with time, the quantum trajectory continuously deforms into a classical trajectory [5]. This means that there is no need to appeal to decoherence to reach the classical domain.
