Introduction

Obesity, a central factor for metabolic syndrome, is caused by the accumulation of neutral lipids in adipose tissues. Based on its structural and functional characteristics, adipose tissue can be classified as white adipose tissue (WAT) or brown adipose tissue (BAT). WAT is a storage organ that converts excess supply calories into neutral lipids. In addition, the neutral lipid storing function of WAT is critical for preventing the accumulation of neutral lipids in other non-adipose tissues, which can result in tissue lipotoxicity [1,2]. However, the hypertrophy of white adipocytes caused by the accumulation of neutral lipids results in the onset of low-grade inflammation in WAT and the induction of systemic insulin resistance. In contrast to WAT, BAT is an energy-consumption organ that metabolizes glucose and fatty acids, and generates heat via mitochondrial uncoupling protein 1 (UCP1) [3,4]. Recently, brown-like adipocytes, defined as beige or brite cells that express UCP1, were identified in WAT. These cells were found to possess thermogenic properties that resemble brown adipocytes [5,6]. Thus, the suppression of inflammation in WAT and the enhancement of energy expenditure in WAT and BAT are expected to be a promising strategy for decreasing obesity and its related diseases.

Sphingolipids, such as ceramide (Cer) and sphingosine, are bioactive lipids that function in membrane structure stabilization, cell-to-cell recognition, and cell signaling [7,8]. Sphingolipid metabolism involves several biomolecules, and is regulated by many enzymes [9]. It was recently reported that a dysfunction in sphingolipid metabolism is responsible for the pathogenesis of several diseases such as cancer, Alzheimer’s disease, and metabolic syndrome [10,11]. Sphingomyelin (SM), one of the most abundant sphingolipids in mammalian cell membranes, is synthesized from Cer and phosphatidylcholine with sphingomyelin synthase (SMS). SMS has three isoforms, SMS1, SMS2, and SMSr. SMS1 localizes to the Golgi apparatus, where it produces an

Abstract

**Background/Objectives:** Adipose tissue (AT) has an important role in energy homeostasis. The dysfunction of AT or the hyper-accumulation of neutral lipids leads to various metabolic diseases. Recent studies indicate that sphingolipid metabolism associates with the development of metabolic diseases. Sphingomyelin, a major sphingolipid in mammals, requires sphingomyelin synthase (SMS) for biosynthesis. Previously, we reported that $Sms2$ deficiency inhibited diet-induced obesity, fatty liver, and insulin resistance in mice. However, the contribution of $Sms2$ to obesity and insulin resistance in AT is largely unknown. In this study, we investigated whether $Sms2$ deficiency in ATs affects obesity and insulin resistance.

**Subjects/Methods:** Wild-type and $Sms2$ knockout (KO) mice were fed a high-fat diet for 12 weeks. Body and AT weights, and the food intake, were recorded. The AT status and macrophage infiltration were evaluated by histological analysis. The expression levels of genes and proteins involved in adipogenesis, inflammation, energy expenditure, and fatty acid metabolism were examined.

**Results:** In white adipose tissue (WAT) from $Sms2$ KO mice, the number of small adipocytes increased but the adipocyte size decreased. In epididymal WAT, $Sms2$ deficiency inhibited inflammation and macrophage infiltration. Moreover, adipogenesis was moderately suppressed. In subcutaneous WAT from $Sms2$ KO mice, the expression of genes involved in energy expenditure and browning (Ucp1, Cidea, Tbx1) was elevated. In brown adipose tissue (BAT) from $Sms2$ KO mice, the lipid droplet surface area was lower than that of WT mice and the expression of genes involved in fatty acid synthesis (Fasn, Scd1) decreased.

**Conclusion:** These results demonstrate that $Sms2$ deficiency leads to moderate adipogenesis and inflammatory suppression in epididymal WAT, increased energy expenditure by the browning of subcutaneous WAT, and suppression of fatty acid synthesis in BAT, suggesting that these synergetic effects in ATs from $Sms2$ KO mice contribute to the suppression of diet-induced obesity and insulin resistance.

Materials and Methods

Animals and diets

Constitutive Sms2 KO mice were generated as previously described [17]. To induce obesity, age- and sex-matched WT and Sms2 KO mice at 4 weeks of age were fed a high-fat diet (60% kcal from fat; 58Y1, TestDiet, Richmond, IN, USA) for 12 weeks. Control mice received a standard chow diet (AIN76A, TestDiet). All mice had access to water and food ad libitum, and were housed under 12 h light and dark cycles in a temperature-controlled room.

The body weights of mice were recorded once a week. The daily food intake was recorded in mice at 8 weeks of age. Rectal temperature was measured at dark cycles using animal thermometer (Natsume Seisakusho, Tokyo, Japan). All experiments were approved by the Animal Care Committee of Hokkaido University.

Histological analysis

Fresh WAT and BAT were fixed in 10% formaldehyde and embedded in optimal cutting temperature compound for cryosectioning. The adipose tissue cross-sections were stained with hematoxylin and eosin. The Sapporo General Pathology Laboratory (Hokkaido, Japan) performed these procedures. The cross-sections were examined under an inverted Olympus CKX41 microscope (Center Valley, PA, USA), and the images were analyzed with ImageJ software (National Institutes of Health, Bethesda, MD, USA). The frequency distribution of the adipocyte surface area was analyzed with SAS (version 2.0; Esumi, Tokyo, Japan).

RNA extraction and quantitative real-time polymerase chain reaction

Total RNA was extracted from adipose tissue and differentiated cells using TRIzol reagent (Invitrogen, Carlsbad, CA, USA) and purified with the PureLink RNA Mini Kit (Invitrogen). To synthesize single-stranded cDNA, reverse transcription was performed using the PrimeScript RT Master Mix (TAKARA Bio, Otsu, Japan) according to the instructions provided by the manufacturer. Quantitative real-time polymerase chain reaction (PCR) was performed using SYBR Premix EX Taq (TAKARA Bio) and the Thermal Cycler Dice Real-Time System (TAKARA Bio). The primers used for quantitative real-time PCR are listed in Supplementry Table 1. The gene expression levels were normalized to hypoxanthine phosphoribosyltransferase (Hprt1) or TATA box-binding protein (Tbp1) in adipose tissue or differentiated cells, respectively.

Table 1: Tissue weight of WT and Sms2 KO mice fed ND and HFD at 15 weeks of age.

|          | WT       | KO       | HFD      | KO       |
|----------|----------|----------|----------|----------|
| Epifat   | 0.78 ± 0.16 | 0.36 ± 0.16* | 2.70 ± 0.22 | 1.11 ± 0.53** |
| Ingrat    | 0.61 ± 0.16 | 0.27 ± 0.14* | 2.09 ± 0.28 | 0.74 ± 0.37** |
| BAT       | 0.09 ± 0.02 | 0.06 ± 0.01* | 0.15 ± 0.03 | 0.08 ± 0.02** |
| Liver     | 0.86 ± 0.07 | 0.84 ± 0.16  | 0.96 ± 0.19 | 0.74 ± 0.1  |
| Kidney    | 0.33 ± 0.02 | 0.32 ± 0.02  | 0.37 ± 0.02 | 0.34 ± 0.03 |

Values are given as mean ± S.D. The significance of differences between the WT and KO within the same condition was analyzed by Student's t-test. (n=11–13; Adipose tissue, n=3–8; Liver and kidneys, *, p<0.05; **, p<0.01.)
Tokyo, Japan) and cultured in a humidified atmosphere of 5% CO2. The medium was changed every other day. The cells were cultured for 5 days and then used for subsequent experiments. The lipid droplets were stained with Nile Red (Sigma) and observed under a FV10i confocal microscope (Olympus).

SDS–PAGE and immunoblotting

SDS–PAGE and immunoblotting were performed according to standard methods described previously [17], anti-UCP1 goat IgG (Santa cruz, CA, USA) and anti-HPRT Rabbit IgG (Santa cruz) were using as the primary anti-body. Anti-goat IgG-HRP and anti-rabbit IgG-HRP (Santa cruz) were using as the secondary antibody. Bands were detected by a Chemi-Lumi one (Nacalai Tesque, Kyoto, Japan).

Statistical analysis

Data were expressed as means ± s. d. Student’s t-test and two-way ANOVA were used for comparison of significant differences. P values<0.05 were considered statically significant. All statically analysis was performed using SAS (version 2.0; Esumi, Tokyo, Japan).

Results

Sms2 deficiency impedes body weight gain and adipose tissue hypertrophy.

To examine the contribution of WAT and BAT in the suppression of diet-induced obesity and insulin resistance in Sms2 KO mice, we fed WT and Sms2 KO mice with a high-fat diet for 12 weeks as previously described [17,19].

The body weights of WT mice fed a high-fat diet increased significantly compared with Sms2 KO mice. In addition, the body weights of WT mice fed a normal diet were moderately higher than those of Sms2 KO mice (Figure 1A).

The average amounts of food intake were not different between Sms2 KO and WT mice (Figure 1B). These results are consistent with our previous report [17].

The weights of the liver, kidneys, and adipose tissues from WT and Sms2 KO mice of both diet groups were recorded. Although the weights of the liver and kidneys from Sms2 KO mice were comparable with those from WT mice (Table 1), the weights of epididymal and subcutaneous WAT and interscapular BAT were significantly lower in Sms2 KO mice than in WT mice (Figure 1C and Table 1).

In addition, body WAT and BAT percentages decreased in Sms2 KO mice compared with WT mice (Figure 1D). These results suggest that S SMS2 is involved in adipose tissue hypertrophy, possibly due to the accumulation of neutral lipids. Sms2 deficiency prevents low-grade inflammation and macrophage infiltration in WAT.

We performed detailed histological analysis of adipose tissues from WT and Sms2 KO mice (Figure 2A). The adipocyte area (2555 µm2) was ~19% less in Sms2 KO mice fed a normal diet compared with the adipocyte area (3156.3 µm2) in WT mice (Figure 2B). As shown in Figure 2B, the frequency of small adipocytes increased in Sms2 KO mice fed a normal diet.

This tendency was also seen in Sms2 KO mice fed a high-fat diet (Figure 2B). In addition, the adipocyte area (5260 µm2) was ~30% less in Sms2 KO mice compared with the adipocyte area (7560.8 µm2) in WT mice.

Adipocyte hypertrophy associates with inflammation and increased macrophage infiltration [20,21]. In epididymal WAT from WT mice fed a high-fat diet, the expression levels of tumor necrosis factor α (Tnfa), monocyte chemotactic protein 1 (Mcp1), and the mature macrophage marker F4/80 were elevated, while the adiponectin expression level decreased (Figure 2C and Supplementary Figure 1A).

However, Sms2 deficiency suppressed the increase in the expression levels of Tnfa, Mcp1, and F4/80. In addition, there was a small but statistically significant increase in adiponectin expression (Figure 2C and Supplementary Figure 1A).

There were no changes in the expression levels of these genes between WT and Sms2 KO mice fed a normal diet. To evaluate macrophage infiltration in WAT, we observed macrophages surrounding dead adipocytes, which form characteristic crown-like structures (CLSs).

Although the number of CLSs was not significantly different between WT and Sms2 KO mice fed a normal diet, the number of CLSs was significantly reduced in Sms2 KO mice fed a high-fat diet.
These results indicate that obesity-induced inflammation and infiltration of macrophages in WAT may be inhibited by Sms2 deficiency.

**Figure 2:** Diet-induced adipocyte hypertrophy and low-grade inflammation are suppressed in epididymal adipose tissue from Sms2 KO mice fed a high-fat diet. (A) Epididymal adipose tissue sections were stained with hematoxylin and eosin. Scale bar=100 μm. (B) Surface area and frequency distribution of adipocytes in epididymal WAT from WT and Sms2 KO mice. Adipocyte surface area was measured with ImageJ software, and the distributions were plotted (n=4–5 mice per group, with >300 cells counted per mouse). (C) Expression of genes involved in differentiation and inflammation (Fabp4, Pparg, Tnfa, F4/80) in epididymal adipose tissue was measured by quantitative real-time PCR (n=5-8 mice per group, *, 0.01<p<0.05, **, p<0.01). The results are expressed as the means ± S.D. (D) Crown-like structures (CLSs, arrows) in epididymal adipose tissue were counted (n=5–7 mice per group). Dead adipocytes surrounded by macrophages were quantified in more than five fields per mouse. The results are expressed as the means ± S.D. Scale bar=100 μm. *, 0.01<p<0.05, **, p<0.01.

**Sms2 deficiency moderately inhibits adipocyte differentiation**

As shown in Figure 2C, the expression of fatty acid-binding protein 4 (Fabp4), a marker of adipocyte differentiation, decreased moderately in Sms2 KO mice fed a normal diet. Compared with WT mice, the expression levels of Fabp4 and peroxisome proliferator-activated receptor γ (Pparg), a key transcription factor involved in adipocyte differentiation, also decreased in Sms2 KO mice at 8 weeks of age (Supplementary Figure B), indicating that Sms2 deficiency reduces adipocyte differentiation. To examine the effects of Sms2 deficiency on adipocyte differentiation, we isolated and cultured SVCs from epididymal adipose tissue to induce differentiation into adipocytes.

**Figure 3:** Sms2 deficiency moderately suppresses differentiation. (A) Preadipocytes isolated from epididymal adipose tissue were cultured to induce differentiation and then stained with Nile Red. Scale bar=50 μm. (B) Frequency distribution of the diameters of lipid droplets (LD) for each class of adipocytes (LD diameter, > 4 μm, 2–4 μm, and<2 μm). More than 100 Nile Red-positive cells were counted in each experiment. (C) Expression of genes involved in adipocyte differentiation (Fabp4, Pparg, Glut4), lipid droplet formation/fusion (Fsp27 and Plin1), and lipid metabolism (Atgl and Hsl) was measured by quantitative real-time PCR. The results are expressed as the means ± S.D. *, 0.01<p<0.05, **, p<0.01. All experiments were independently repeated at least three times.

**Sms2 deficiency is involved in the browning of subcutaneous WAT**

To examine the effects of Sms2 deficiency on subcutaneous adipose tissue, we performed histological analysis of adipose tissue from WT and Sms2 KO mice (Figure 4A).

Histological analysis revealed that the surface area of adipocytes from Sms2 KO mice fed a normal or high-fat diet decreased compared to WT mice (Figure 4A, B). In addition, the number of small adipocytes increased in Sms2 KO mice fed a normal or high-fat diet compared to WT mice (Figure 4A, B).
The results from this analysis were comparable to those from the epididymal adipose tissue analysis (Figures 2A and 2B). However, the expression levels of Fabp4 and Pparg in subcutaneous WAT were not different between WT and Sms2KO mice (Figure 4C).

**Figure 4**: Expression of genes involved in energy expenditure and browning in subcutaneous adipose tissue from Sms2KO mice fed a high-fat diet is increased. (A) Inguinal adipose tissue sections were stained with hematoxylin and eosin. Scale bar=100 μm. (B) Surface area and frequency distribution of adipocytes in inguinal WAT from WT and Sms2KO mice. Adipocyte surface area was measured with ImageJ software, and the distributions were plotted (n=3 mice per group, with >180 cells counted per mouse). (C) Expression of genes involved in differentiation (Fabp4 and Pparg, as well as the expression of brown adipocyte markers (Ucp1, Cidea, Prdm16)) and the beige adipocyte marker Tbx1 in inguinal adipose tissue, was measured by quantitative real-time PCR (n=3–6 mice per group, *, 0.01<p<0.05, **, p<0.01). (D) Immunoblotting of UCP1. UCP1 protein expression was normalized loading control HPRT1. (E) Body temperature of WT and Sms2KO mice fed a high fat-diet at 16 weeks of age (n>9, **, p<0.01). The results are expressed as the means ± S.D.

Subcutaneous WAT browning associates with increased energy expenditure, which decreases obesity and improves glucose intolerance [5,6].

Thus, we investigated the expression level of the beige adipocyte marker Tbx1, as well as the expression levels of genes involved in thermogenesis (uncoupling protein 1 (Ucp1), cell death-inducing DEFFA-like effector A (Cidea), PR domain 16 (Prdm16)). Except for Prdm16, there were no changes in their expression levels between WT and Sms2KO mice fed a normal diet.

On the other hand, the expression levels of Ucp1, Cidea, and Tbx1 increased significantly in Sms2KO mice fed a high-fat diet (Figure 4C).

In addition, Ucp1 protein expression level was slightly but significantly increased (Figure 4D). In concordance with the elevated expression of Ucp1, the rectal temperature was higher in Sms2KO mice fed a high-fat diet than in WT mice fed a high-fat diet (Figure 4E). These results indicate that the browning of subcutaneous WAT is induced in Sms2KO mice.

**Fatty acid synthesis is suppressed in BAT of Sms2KO mice**

We performed histological analysis of BAT from WT and Sms2KO mice. There were many multilocular lipid droplets present in BAT from WT mice fed a normal diet. However, the lipid droplets underwent hypertrophy in WT mice fed a high-fat diet (Figure 5A). In BAT from Sms2KO mice, the lipid droplets were very small, and an increase in surface area was inhibited by a high-fat diet (Figure 5A). Thus, we hypothesized that energy expenditure was induced or/and brown adipocyte differentiation was suppressed in Sms2KO mice. To test this hypothesis, we investigated the expression levels of genes involved in adipocyte differentiation (Fabp4 and Pparg, glucose uptake (Glut4), and energy expenditure (Ucp1, Cidea, Prdm16)). Except for Prdm16, there were no changes in their expression levels between WT and Sms2KO mice (Figure 5B). We also investigated the expression levels of genes involved in fatty acid β-oxidation and synthesis (acyl-CoA oxidase 1 (Acox1), carnitine palmitoyltransferase 1b (Cpt1b), fatty acid synthase (Fasn), stearoyl-coenzyme A desaturase 1 (Scdc1)). Compared to WT mice fed normal and high-fat diets, the expression levels of Acox1 and Cpt1b were similar in BAT from Sms2KO mice fed normal and high-fat diets.

**Figure 5**: Fatty acid synthesis is suppressed in BAT from Sms2KO mice fed normal and high-fat diet. (A) Brown adipose tissue sections were stained with hematoxylin and eosin. Scale bar=50 μm. (B) Expression of genes involved in differentiation (Fabp4 and Pparg, and fatty acid metabolism and synthesis (Cpt1, Acox1, Fasn, Scd1), as well as the expression of brown adipocyte markers (Ucp1, Cidea, Prdm16), was measured by quantitative real-time PCR (n=5–13 mice per group, *, 0.01<p<0.05, **, p<0.01). The results are expressed as the means ± S.D.

However, the expression levels of Fasn and Scd1 decreased significantly in BAT from Sms2KO mice fed normal and high-fat diets (Figure 5B). These results indicate that fatty acid synthesis is suppressed in BAT from Sms2KO mice but that fatty acid oxidation is normal.
Discussion

Mitsutake et al. reported that Sms2 KO mice fail to develop diet-induced obesity, systemic insulin resistance, and liver steatosis [17]. However, there is no study on the roles of WAT and BAT, which associate with the development of metabolic diseases, in Sms2 KO mice. In this study, we investigated whether WAT and BAT from Sms2 KO mice contribute to the suppression of diet-induced obesity and insulin resistance. The body weights of Sms2 KO mice, as well as the weights of different adipose tissues, were reduced compared with WT mice. High-fat diet-induced adipocyte hypertrophy and low-grade inflammation were also inhibited in epididymal WAT from Sms2 KO mice. Moreover, adipocyte differentiation was moderately inhibited in Sms2-deficient white adipocytes. Energy expenditure increased by the recruitment and activation (browning) of beige adipocytes in subcutaneous WAT from Sms2 KO mice. In BAT from Sms2 KO mice, fatty acid synthesis was inhibited. These findings indicate that Sms2 deficiency in adipose tissues suppresses diet-induced obesity and insulin resistance.

Several studies reported that adipocyte hypertrophy increases the surface area of visceral adipose tissue in diet-induced or genetically obese mice, leading to the development of low-grade inflammation [24,25]. However, the increased adipose tissue weight, the adipocyte hypertrophy, the macrophage infiltration, and the expression levels of inflammatory cytokines and chemokines (Figure 2) were inhibited in epididymal adipose tissue from Sms2 KO mice. Hailemariam et al. reported that the activation of nuclear factor-kappa BNFκB), a central inflammatory factor, was attenuated in macrophages isolated from Sms2 KO mice [26]. An inhibition of chronic inflammation in adipose tissue from obese subjects can improve insulin sensitivity via an increase in serine/threonine-protein kinase (Akt) phosphorylation [27,28]. Indeed, Sugimoto et al. reported that Akt phosphorylation increased in visceral adipose tissue from Sms2 KO mice [29]. Therefore, the improvement of insulin sensitivity in adipose tissue from Sms2 KO mice via an inhibition of inflammation may contribute to the suppression of systemic insulin resistance. The surface area of white adipocytes from Sms2 KO mice was lower than that of WT mice fed normal and high-fat diets (Figure 2). Moreover, the expression levels of Pparg and Fabp4 decreased in Sms2 KO mice (Figure 2 and Suplementary Figure 1B). Consistent with these results, preadipocytes isolated from WAT from Sms2 KO mice matured slower than those isolated from WAT from WT mice (Figure 3). The body weights, as well as the weights of adipose tissues, decrease in adipose tissue-specific Pparg KO mice, because adipocyte differentiation is insufficient [30]. These results reveal that moderate defects in adipocyte differentiation in Sms2 KO mice underlie the reduction in adipose tissue mass and the increased number of small adipocytes. Although the food intake in WT and Sms2 KO mice fed a high-fat diet was not changed, the body weights of Sms2 KO mice fed a high-fat diet were significantly lower than those of WT mice (Figure 1). These results led us to conclude that energy expenditure is increased in Sms2 KO mice. A recent study reported an increase in energy expenditure during the recruitment of beige adipocytes in subcutaneous adipose tissue but a decrease in diet-induced obesity [6]. Furthermore, it is reported that many of genetic modification mice that resist to diet-induced obesity showed that browning in subcutaneous adipose tissue [6, 31-35]. In subcutaneous adipose tissue from Sms2 KO mice fed a high-fat diet, the expression levels of genes involved in browning (Ucp1 and Cidea), as well as the expression level of the beige adipocyte marker gene Tbx1, increased compared to WT mice (Figure 4). These results raise the possibility that the browning of subcutaneous fat in Sms2 KO mice may be one of the causes of diet-induced obesity resistance. However, other explanations also exist such as poor intestinal absorption of triglycerides or hyperactivity. The intestinal absorption of triglycerides (TGs) in Sms2 KO mice may have few effects, because the fecal TGs contents in Sms2 KO mice were comparable to those in WT mice (data not shown). To evaluate hyperactivity in Sms2 KO mice, however, the voluntary activity will have to be measured. It is also important to investigate the effects of Sms2 deficiency on sympathetic activity, because sympathetic neurons and neuropeptides are involved in the regulation of adipose tissue function [36-38].

Lodhi et al. reported that Fasn deficiency in adipose tissue increased energy expenditure, resulting in subcutaneous adipose tissue browning and a lean phenotype [23]. The authors also indicated that alkyld ether phosphatidylcholine species, which act as PPARy agonists, decreased in adipose tissue-specific Fasn KO mice. In Sms2 KO mice, on the other hand, Fasn expression in BAT decreased significantly (Figure 5). In addition, the expression levels of genes involved in browning (Ucp1, Cidea, Tbx1) increased in subcutaneous adipose tissue (Figure 4). Recently, Xia et al. reported that dynamic crosstalk exists between siphingolipids in the liver and adipose tissue, and that this bidirectional transport of siphingolipids is important for the regulation of glucose metabolism and hepatic lipid uptake. Moreover, an alteration of siphingolipid composition in adipose tissues induced a quicker and stronger resolution of hepatic steatosis than that of siphingolipid composition in the liver [39]. Although we have not yet analyzed the siphophospholipid and siphingolipid composition in adipose tissue, changes in the composition of phospholipids and siphingolipids in adipose tissues from Sms2 KO mice might contribute to the browning of subcutaneous fat, and the suppression of liver steatosis and insulin resistance in these mice. To address these possibilities, the composition of different lipids should be analyzed in tissue-specific conditional Sms2 KO mice. SMS1, an isoform of SMS, localizes to the Golgi apparatus. It is responsible for synthesizing most of the SM [13]. Similar to Sms2 KO mice, Sms1 KO mice exhibited a lean phenotype and a decreased WAT weight. However, mitochondrial dysfunction and increased oxidative stress can affect adipose tissue function, subsequently resulting in hypertrygliceridemia (lipodystrophy) [15,16]. On the other hand, Sms2 KO mice exhibited a decreased WAT weight (Figure 1), but not hypertrygliceridemia [17]. There were no changes in the expression levels of genes involved in mitochondrial function (Acox1, Cpt1b, Ucp1) in WT mice fed a normal diet (Figure 5). Moreover, oxidative stress derived from mitochondrial disfunction in adipose tissues was not changed between WT and Sms2 KO mice (Suplementary Figure 2). Therefore, the mitochondrial function in adipose tissues from Sms2 KO may be normal. In contrast to SMS1, SMS2 localizes predominantly to the plasma membrane, and it is important for the maintenance of SM levels in lipid rafts [12-14,17]. Thus, the regulation of SM levels or the maintenance of lipid rafts in the plasma membrane via SMS2 activity may be involved in adipocyte differentiation, inflammation, and browning, as well as the regulation of the fatty acid synthesis pathway.

Conclusion

Sms2 deficiency leads to moderate defects in adipocyte differentiation and the suppression of inflammation in visceral fat, increased energy expenditure by the browning of subcutaneous fat, and the suppression of fatty acid synthesis in BAT. These synergetic effects in adipose tissues caused by Sms2 deficiency may contribute to
the suppression of diet-induced obesity and insulin resistance. Additional studies are needed to precisely define the role of SMS2 in adipose tissue.
