The Study In Vitro of the Effects of the Inhalant Corticosteroids on Oral and Laryngeal Mucosa

Menicagli Roberto and Marotta Ortensio*

Senior Researcher in Biochemistry, Roma Biomed Research, Martiri Libertà 6/a 20060 Mediglia, Italy

Abstract

Background: The pharmacology activity of corticosteroids, is due to the formation in the blood of the complex Corticosteroid-Protein Glycosylated, that, in this form, after the binding to the cytoplasmic receptor, penetrates in the target cells. This interaction process, also happens, with salivary proteins The aim of this study is, to study this process, that precipitate the salivary proteins, and with them, the salivary secreted mucin.

Materials and methods: In two samples of whole saliva provided by volunteers, are added different concentrations of three corticosteroids, beclometasone, budesonide, fluticasone. The samples are centrifuged, and in surnatant, dosed, the amounts of total salivary proteins and mucins. The results are statistically analyzed with Mann Whitney U Test, Test T, Pearson Correlation Coefficient

Results and discussion: With all dosage, the difference of the proteins and mucins precipitated by the Budesonide, and beclometasone vs fluticasone, are statistically different., p ≤ 0.05. For all three corticosteroids, there is a saturation value, with a good correlation between corticosteroid’s dosage and the amount of the protein-mucins precipitation, (Pearson coefficient of 0.91). The little difference in the precipitation of the mucins, and the proteins, p=0.0334, obtained with the budesonide versus beclometasone, can find an explanation, for the presence in the first, of two hydroxyl groups, (one in beclometasone). The difference of beclometasone and budesonide, versus fluticasone, is due assuming that the parameters, that stabilize the (CCP), type hydrogen bonds and Van der Waals forces, are more influenced by solubility in water, there is nothing for the fluticasone, rather than by the chemical conformation of drugs

Keywords: Corticosteroid; Aerosol; Precipitation; Proteins; Salivary mucins

Introduction

For its anti-inflammatory properties, cortisone medications are used successfully in the treatment of respiratory diseases such as asthma, pulmonary fibrosis. The pharmacology of corticosteroids is very complex, but can be summed up with the explication of these activities:

1. Interaction and complex formation Corticosteroid-Protein Glycosylated (GR) - (CCP)
2. Transport inactivated form of (CCP) to the target cells
3. Penetration (CCP) in the cells and binding to the cytoplasmic receptor
4. Anti-inflammatory corticosteroid activity: the complex (CCP) penetrates into the nucleus and interacts with the DNA activating or inhibiting gene transcription, responsible of the major pharmacological effects of corticosteroids. The complex, in addition, is able to block the way of NFkB (nuclear factor kappa-light-enhance of activated B cells, the key of many mechanisms in inflammatory and immunological diseases). In those passages, the formation of a “Protein-Corticosteroid” complex, that allows the transport of corticosteroids, has a key rule

In the blood, this training, involving approximately eighty percent of the concentration of the corticosteroid, is between the same (position C19 and C23), and a protein that is a non-inhibitory member of the serine proteinase inhibitor (serpin) super-family, and have high-affinity transport protein for corticosteroids in blood. plasma. CBG is a glycoprotein with 30% of its mass represented by N-linked oligosaccharide chains (Chuang C K2. Recent crystal structure analyses of intact rat CBG and cleaved human CBG have revealed the precise topography of the steroid-binding site, and shown that cortisol-bound CBG displays a typical stressed (S) serpin conformation with the Reactive Center Loop (RCL) fully exposed from the central beta-sheet [1-4]. Corticosteroids can also pair with other proteins and their affinities can vary greatly [5]. In function of many parameters, these bonding mechanisms have been studied in order to understand both the anti-inflammatory capacity of cortisone is some of the possible side effects of these drugs. These variations actually depend not only on the type of chemical structure of cortisone compounds, but as it has been shown recently also, and perhaps more than that of proteins. In particular may occur naturally or not, modifications/alterations in the glycosylation process of the serum proteins, which involves a variation in the percentage of the carbohydrate part [6-12]. These changes modify the protein folding in a definitive way with consequences both in terms of possible catalytic activities of proteins. Both in the processes of interaction of the same, with different substrates as it is clear that the process and interaction / binding between proteins and corticosteroids easily occurs in the blood. with the formation of a stable complex, that reasonably can also happen in the saliva. In this medium, also are not present globulins, which in the blood have the highest affinity with the corticosteroids, and therefore they can bind with the various proteins present. This fact could change their functionality and their role, that

is critical to the defences of the oral cavity and larynx. In a precedent study, we have showed, as the interaction salivary proteins with two different corticosteroids, used as inhalant drugs, in asthmatic people, interacting with salivary proteins, they may precipitate an amount that at therapeutic doses, reached about 20. Therefore, salivary protein-drug interactions play a key role in pharmacokinetics and pharmacodynamics of the drugs. And in particular mucin-drug interaction may have important effects on the drug absorption, (mucus is the first barrier that drugs must overcome to be adsorbed and gain access to the circulatory system) and distribution, (only the free concentration of drug can get to the target and produce a biological response). This means that a high binding may reduce the drug’s pharmaceutical effect.

Beyond the types of nebulizers used in aerosol therapy, it must be emphasized that it is not associated only in the winter season and with colds, but also the spring and allergic phenomena, which occur more and more numerous in this season. Therefore, the constant use of corticosteroids may lead to increased side effects because of the latter, they should be used with caution. Corticosteroid drugs often inhale can lead to hoarseness, with atrophy of the vocal cords, fungal lesions, and xerostomia. The hypothesis is that, these interactions, involve the most important proteic components of the oral mucus, the salivary secreted mucins, MUC 7 and MUC5B. Since mucus acts as a barrier, there are two main mechanisms that limit diffusion through mucus gel: (a) interaction with mucus components (i.e., electrostatic and hydrophobic interactions with mucins), and (b) size filtering related to the size of the mesh spacing between mucin fibers. Many studies highlighted that no definitive picture of the nature of the molecular interactions between drug molecules and the mucin components can be drawn... this mechanism, has already been clarified in part, in a qualitative way, by means of spectrophotometric studies, UV-Vis spectroscopy showed that, the prednisolone drug, can bind to mucin to form a protein-drug complex. Fluorescence data proved that mucin fluorescence can be quenched by the studied drug and that the quenching is governed by a dynamic quenching for mucin and interaction, with prednisolone, with the occurrence, according to thermodynamic parameters, with hydrophobic, hydrogen bonds and van der Waals forces, that may play a major role in stabilizing mucin-prednisolone and mucin-complexes. Purpose of this our study, is to obtain quantitative data, of these interaction processes, verifying, possible differences between different corticosteroids ee possibly between the total salivary proteins, and the mucin fraction, based on the quantity precipitated

Materials and Methods

The whole saliva samples, 10 ml, were provided by a male volunteer aged 30 years, who are not smoking, not denounced cardiovascular diseases the amounts of the samples of saliva are those produced in an average time it takes for one cycle of the aerosol therapy. In saliva samples before and after the addition of corticosteroids, were determined the concentrations of the total protein by the Biuret test at, the pH with digital ECO, while for the dosage of total salivary mucins were used the Alcian Blue.

Method

Three samples of corticosteroids, are been used, and their commercial properties are as follow:

1. Beclomethasone dipropionate: 0.8 mg/2 ml suspension to be nebulized aerosol

Single-dose vials of 2 ml aerosol Composition 100 ml of sterile suspension containing:

- Active ingredient: beclomethasone dipropionate 0.040 g. Excipients: Sodium chloride; Polysorbate 20; Sorbitan monolaurate; Water for injections:
  - 1. Budesonide 0.5 mg/ml suspension nebulizer 1 single dose container contains: Active ingredient: 1 mg busedonide
  - 2. Fluticasone Inhalation Powder 100, 250 and 500 micrograms of fluticasone propionate pressurized inhalation, suspension from 50, 125, 250 mcg of fluticasone propionate.

After the addition of corticosteroids, to saliva, the same samples were subjected to centrifugation a 4000 rpm for two minutes. In the surrnatant were determined by the methods mentioned above, the total mucin and the total proteins. The results are statistically analyzed with Mann-Whitney U Test, and Pearson Correlation Coefficient. The Mann-Whitney U Test is a nonparametric test that allows two groups or conditions to be compared without making the assumption that values are normally disturbed.

Requirement: the data is continuous, scale of measurement should be ordinal, interval of ratio Pearson Correlation Coefficient is used to measure the strength of a linear association between two variables, where the value r=1 means a perfect positive correlation and the value r=1 means a perfect. The results for the difference of the precipitation of the mucins by the three corticosteroids are statistically analyzed, with T Test, two-tailed, in identical variance

Results

In the first three tables, are showed, the results of the amount of total salivary protein and mucin precipitated, in function of each single corticosteroid, while in Table 4 are indicated only the differences relating to mucins, only to highlight the average value of their precipitation as a function the average concentration of corticosteroid used (Table 1).

Results of statistical analysis

Mann-Whitney u test for beclometasone: Total proteins vs total mucins.

The U-value is 59.5. The critical value of U at p<0.05 is 45. Therefore, the result is not significant at p<0.05.

The Z-Score is -1.23443. The p-value is 0.2187. The result is not significant at p<0.05 (Scheme 1 and Table 2).

Results of statistical analysis

Mann-Whitney u test for budesonide: Total proteins vs total mucins.

The U-value is 58. The critical value of U at p<0.05 is 37. Therefore, the result is not significant at p<0.05.

The Z-Score is -0.77942. The p-value is 0.4354. The result is not significant at p<0.05 (Scheme 2 and Table 3).

Results of statistical analysis

Mann-Whitney u test for fluticasone: Total proteins vs total mucins.

The U-value is 68. The critical value of U at p<0.05 is 37. Therefore, the result is not significant at p<0.05.

The Z-Score is -0.20207. The p-value is 0.84148. The result is not significant at p<0.05.

The U-value is 68. The critical value of U at \( p < 0.05 \) is 37. Therefore, the result is not significant at \( p < 0.05 \) (Scheme 3 and Table 4).

Test T for budesonide vs beclometason; \( p = 0.334; p \geq 0.05 \)

Test T for beclometasone vs fluticasone; The t-value is \(-3.52189\). The p-value is 0.003385. The result is significant at \( p < 0.05 \).

Test T for Budesonide vs fluticasone; The t-value is \(-3.79393\). The p-value is 0.000882. The result is significant at \( p < 0.05 \).

Pearson correlation coefficient mg beclometasone vs % mucins Precipitation.

The value of R is 0.940. This is a strong positive correlation, which means that high X variable scores go with high Y variable scores (and vice versa).

Pearson correlation coefficient mg Budesonide vs % mucins Precipitation: The value of R is 0.904. This is a strong positive correlation, which means that high X variable scores go with high Y variable scores (and vice versa).

Pearson correlation coefficient mg fluticasone vs % mucins Precipitation.

The value of R is 0.8912. This is a strong positive correlation, which means that high X variable scores go with high Y variable scores (and vice versa) (Figures 1-3).

**Table 4:** Addition of the corticosteroids and precipitation percentage of salivary mucins.

| Beclometasone | Budesonide | Fluticasone |
|---------------|------------|-------------|
| mg            | % Precipitation mucins | mg            | % Precipitation mucins | mg            | % Precipitation mucins |
| 0.1           | 4           | 0.1         | 4                   | 0.1           | 0                      |

**Discussion**

The above results, in relation to total salivary proteins, confirm the results of our previous study [7], although the amount of proteins precipitated by beclometasone and Budesonide is lower. As far as the protein fraction of mucins is concerned [10], where patients treated with high doses of Inhaled Corticosteroids showed lower levels of salivary MUC5B compared with those treated with medium Inhaled Corticosteroids doses or those not treated. In this study, experimentally, compared to the our previous research, the corticosteroid after its

addition to saliva, after its addition to saliva, was highly dispersed with a micro vibrator, rather than leaving the complex to slowly sediment alone. So after, this process, the suspension that is obtained, see Figure 4, it was centrifuged for two minutes at 4000 rpm and not allowed to decant, thus obtaining a supernatant, absolutely clear see Figure 5. Notably, precisely, in reference to the previous results, that this time, there is a little difference in the amount of salivary proteins precipitated, and this difference, it is due to the addition of Budesonide, rather than to Bclomethasone. In any case, the differences, for the three corticosteroids, have a constant trend, see Tables 1 and 2, for all added amounts of corticosteroids. These results, however, can be to find a logical explanation, admitting that the main forces that govern the interaction process leading to the formation and stabilization of Protein-corticosteroid complex, are the hydrogen bonds, hydrophobic interactions, and van der Waals forces. These may play a major role in stabilizing proteins-corticosteroid complex, as happen, for example, when are added in saliva the polyphenol compounds, with the result, that also in small concentration of the same, there is the total proteins precipitation. In this case a fundamental rule is two to the Hydrogen bonds that are established between the hydroxyl groups (OH) of polyphenols and the carbonyl (C=O), of the amino acids of proteins.

In Budesonide in fact there are two hydroxyl groups, one only in beclomethasone, see figures and equal solubility in an aqueous environment, which is still very low, this fact may justify the results of Tables 1, 2 and 4. The precipitation data, detect very low concentration both in the precipitation of cghe protine of mucins, with statistically significant differences compared to that sial Budesonide Bclomethasone, and this depends on practically insolubility of this corticosteroid in an aqueous environment. All factors mentioned above, make that the corticosteroids compounds can easily interact with the proteins. And also with the mucins by setting the characteristic of the colloidal structure. These structures take the form of polymers dispersed in saliva, with the physical properties of colloids and in particular their stability in the dispersing phase, in our case the saliva, depend on the electrical double layer. That characterizes the protein of the double layer interface, or generated by the electrical potential, called Z. The potential formation of links between a single corticosteroid molecule and a protein colloidal particle deforms the latter structure, change the interface of the double layer, changing the Z potential and it has the precipitation. The results expressed in Tables 1-3, also show that there are no statistically significant differences in the amounts of precipitated proteins, compared to mucins, and this indicates that the glycosylated part of the same, is irrelevant in, probably because the interaction processes structure sugary, subtracts water to the system, with a solvation process that tends to isolate the protein part (Figure 6).

Conclusion

This fact, together with the low solubility of corticosteroids, almost nothing for fluticasone, the system leads to a quick saturation, practically for a 1.6 mg dosage, as you can see from the figures and from the respective tables.
