ABSTRACT: We analyse the noncommutative U(1) sigma model, which arises from the vacuum dynamics of the noncommutative charged tachyonic field. The sector of “spherically symmetric” excitations of the model is equivalent to a chain of rotators. Classical solutions for this model are found, which are static and “spherically symmetric” in noncommutative spatial dimensions. The limit of small noncommutativity reveals the presence of Polyakov vortices in the model. A generalisation of the model to $q$-deformed space, which may serve as a regularisation of the non-deformed model is also considered.

KEYWORDS: Noncommutative geometry, branes, vacuum.
1. Introduction

The noncommutative geometry [1], proved to be an utile tool in the brane dynamics of string theory [2].

Thus, the low energy effective action for a p-brane in the presence of nonzero constant $B_{\mu\nu}$ field along the brane is given by the dimensional reduction of the 10-dimensional noncommutative Yang–Mills model to the brane world volume [3].

In the limit of large field $B_{\mu\nu}$, i.e. when by some matrix norm,

$$\alpha'^{\mu\nu} \ll \|g_{\mu\nu}\|,$$

(1.1)

the noncommutativity parameter $\theta_{\mu\nu}$ is given by the inverse matrix to $B$ [2],

$$\theta_{\mu\nu} = (B^{-1})_{\mu\nu},$$

(1.2)

while the open string metric along the brane is given by,

$$G_{\mu\nu} = -(2\pi\alpha')^2 (Bg^{-1}B)_{\mu\nu},$$

(1.3)

and the Yang–Mills coupling,

$$g_{YM}^2 = \frac{(2\pi)^{p-2}G_s}{(\alpha')^{1+2}},$$

(1.4)

where, $G_s$ is the open string coupling. In this limit the stringy corrections decouple and the model is described by the effective noncommutative theory [2, 4].
From the other hand, in the case of a brane-antibrane pair or of a non-BPS non-stable brane one finds in the spectrum of the effective theory tachyonic modes as well. In the above limit, the tachyonic mode is described by noncommutative scalar field(s) $T$ with potential $V(T)$ (tachyonic potential) [5, 6, 7].

The action for brane system containing a tachyonic mode in this case looks as one for the noncommutative scalar field interacting with U(1) gauge field [8, 9],

$$S_{\text{Brane}} = \int d^{p+1}x \left( -\frac{1}{4g^2} \eta_{\mu\alpha} \eta_{\nu\beta} F_{\mu\nu} \ast F_{\alpha\beta} + \eta_{\mu\nu} \frac{1}{2} f(T) \ast \nabla_\mu T \ast \nabla_\nu T - V(T) \right),$$

(1.5)

where $\eta_{\mu\alpha} = \text{diag}(1, -1, \ldots, -1)$ and we put the brane tension equal to unity. In the above equation all products are understood as star products, defined by

$$A \ast B(x) = e^{i \theta_{\mu\nu} \partial_\mu \partial_\nu} A(x) B(x') \bigg|_{x' = x}. \quad (1.6)$$

The star product can be viewed as one of possible representation of the algebra of operators acting on some Hilbert space $\mathcal{H}$, integral given by the trace.

The tachyonic potential is known to have a local maximum at the origin and global minimum for some constant, i.e. $c$-number value $T^*$ of the field. In the case of superstrings the potential is even with respect to the inversion $T \to -T$, and there is also minimum at $-T^*$.

In the case of zero gauge fields one can find a solution to the equations of motion of the tachyon $T$ in the limit of the large noncommutativity parameter $\theta$ when the kinetic term is negligible in comparison with potential one in the equations of motion [10]. Such a solution is given by $T_0 = T^* P(x)$, where $P(x)$ is the noncommutative function corresponding to some projector $P \ast P = P$.

In the presence of the nontrivial gauge field one can find solution of the similar type as above [11, 12]. In this case the solution implies such gauge field configurations for which the tachyonic soliton is covariantly constant,

$$\nabla_\mu T_0 = 0, \quad (1.7)$$

and requirement for noncommutativity parameter $\theta$ to be large is no more needed.

The meaning of these solutions consists in the description of the smaller branes living on the original $p$-brane [13].

To obtain the solutions one uses only the minima of the potential and the fact that the tachyonic field is covariantly constant, but not the details of the kinetic term and interaction potential. If, however, one is interested in the spectrum of fluctuations around such a vacuum solution these details may become important.

In this paper we introduce the model of the noncommutative U(1)-field having some relation to the tachyonic vacuum. We find and analyse solutions which neither

---

1This limit, however, should be consistent with, eq. (1.1).
appear in the commutative case nor fall in the class of solutions of the described above projector type.

The plan of the paper is the following. In the next section we consider a model of noncommutative charged Higgs-like field whose vacuum dynamics yields a noncommutative sigma model ($U$-field). We give some kind of string motivation for the model under consideration, however, the model itself presents a separate interest. In the third section we analyse equations of motion, local extrema, and geometrical meaning of the $U$-field. In the fourth section we extend these results to the model living on $q$-deformed space, which can be treated as a regularisation of the model above. In the fifth section we show, that in the commutative limit one can treat $U$-field as a free scalar field surrounded with the gas of Polyakov vortices. Finally, we discuss our results.

2. Charged Tachyon

Consider the noncommutative Higgs-like model of charged scalar fields (charged noncommutative tachyon) in the trivial noncommutative gauge field background. It is given by the action,

$$S = \int d^{p+1}x \left( \frac{1}{2} \eta^{\mu\nu} \partial_{\mu} \phi \ast \partial_{\nu} \phi^\dagger - V(\phi \ast \phi^\dagger) \right),$$

(2.1)

where $V(\cdot)$ is a potential with a nontrivial v.e.v.: $|\phi|^2 = $ some constant.

The field $\phi$ transforms in the bi-fundamental representation of the U(1) gauge group. Such fields were considered earlier in [14].

In general, (bi-)fundamental modes arise in the spectrum of the nonstable branes [8, 12]. These modes correspond to strings which have only one end on the brane. Since in the compactified theory a string cannot end elsewhere it was conjectured by [5, 15], that such modes are absent. The “confinement” mechanism for these modes is as follows. Close to the tachyonic vacuum the kinetic part of the noncommutative gauge field vanishes and the gauge potential starts to play the role of the Lagrange multiplier for the charged currents forcing them to vanish.

In the case of non-compact Minkowski space there is also the possibility to have strings with one end at the infinity. Although the energy cost of such strings is large their presence may change the situation. Indeed, if there is some nontrivial v.e.v. for the charged field, which correspond to a tachyonic mode of the semi-infinite strings, the above described mechanism does not freeze all the degrees of freedom, since there remain ones connected with gauge motion along the vacuum valley.

A point in the (true) vacuum of the field $\phi$ can be parameterised by an element of the noncommutative U(1),

$$\phi \to U \ast \phi,$$

(2.2)

$$\phi^\dagger \to \phi^\dagger \ast U^{-1},$$

(2.3)
where \( U \) and \( U^{-1} \) satisfy \( U * U^{-1} = U^{-1} * U = 1 \). \( U \) act transitively along the vacuum valley.

To get the action describing the dynamics along the valley of the potential \( V \) in terms of field \( U \), let us take a constant \( \phi \) realising the minimum of the potential. After that, perform the transformation (2.2) and declare the field \( U \) dynamical. The action for the Goldstone \( U \)-field looks as follows,

\[
S = \frac{1}{\lambda^2} \int \! d^{p+1}x \, \eta^{\mu \nu} \partial_\mu U * \partial_\nu U^{-1} = \frac{1}{\lambda^2} \int \! d^{p+1}x \, \eta^{\mu \nu} \partial_\mu U * U^{-1} * \partial_\nu U * U^{-1},
\]

(2.4)

where the coupling \( \lambda \) is given by \( 1/\lambda^2 = \phi * \phi^\dagger = \text{constant} \).

The model (2.4) describes the tachyon fluctuations along the degenerate vacuum. In the limit of large \( \theta \) the remaining fluctuations decouple and the action (2.4) describes all the tachyonic degrees of freedom. In what follows we do not assume large or small value of the noncommutative parameter, except the Section 5 where we consider the limit of small \( \theta \).

Let us note that a model of U(1)-field was considered in [16], in the limit of strong noncommutativity when one can neglect the kinetic term.

### 3. The noncommutative \( U \)-field

Consider the case \( p = 2 \). We assume that two spatial coordinates are noncommutative,

\[
[x^1, x^2] = \mathrm{i} \theta,
\]

(3.1)

while time coordinate is commutative. In this paper we assume Minkowski signature and the commutative time. For definiteness, consider \( \theta > 0 \), the case of negative \( \theta \) can be reduced to one under consideration by interchange, of \( x^1 \) and \( x^2 \).

Equations of motion corresponding to the action (2.4) look as follows,

\[
- \partial^2 U^{-1} + U^{-1} * \partial^2 U * U^{-1} \equiv
- \ddot{U}^{-1} + U^{-1} * \dot{U} * U^{-1} + \partial_1^2 U^{-1} - U^{-1} * \partial_2^2 U * U^{-1} = 0,
\]

(3.2)

where \( i = 1, 2 \).

Consider this equation in the operator form, and let us search for classical solutions. For this it is useful to pass to “complex coordinates” given by oscillator representation, and work in terms of operators,

\[
a = \frac{1}{\sqrt{2\theta}} (x^1 + \mathrm{i} x^2), \quad \bar{a} = \frac{1}{\sqrt{2\theta}} (x^1 - \mathrm{i} x^2), \quad N = \bar{a} a,
\]

(3.3)

\[
[a, \bar{a}] = 1, \quad N a = a (N - 1), \quad N \bar{a} = \bar{a} (N + 1).
\]

(3.4)
Assume the “spherically symmetric” ansatz \( U(N, t) \equiv U_N(t) = e^{iu_N(t)} \) (see e.g. [10]), then the equation for the ansatz translates to,

\[
\ddot{u}_N = \frac{2}{\theta} [(N + 1) \sin(u_{N+1} - u_N) - N \sin(u_N - u_{N-1})]. \tag{3.5}
\]

The equations of motion can be integrated back to an action. The action one gets coincides with simple reduction of the original action (2.4) to the ansatz,

\[
S = \frac{2\pi\theta}{\lambda^2} \int_{-\infty}^{+\infty} dt \left\{ \left(\dot{u}_N \right)^2 - \frac{4}{\theta} N [1 - \cos(u_N - u_{N-1})] \right\}, \tag{3.6}
\]

It describes the “spherically symmetric” excitations in the model of \( U \)-field. Further we will consider only the degrees of freedom of this type. The action (3.6) and equations of motion (3.5) are given in the operator form and we use the equivalence between noncommutative integrals and traces,

\[
\int d^2x(\cdot) \equiv (2\pi\theta) \text{tr}(\cdot).
\]

Let us note that this generalises to the case of \( p = 2k \) noncommutative coordinates, where one has the action

\[
S = \frac{(2\pi\theta)^k}{\lambda^2} \int_{-\infty}^{+\infty} dt \left\{ \left(\dot{u}_N \right)^2 - \frac{4}{\theta^k} N_\delta [1 - \cos(u_N - u_{N-\delta})] \right\}, \tag{3.7}
\]

where \( N \) is a vector formed of \( k \) oscillator level number operators, taking values in \( k \)-dimensional lattice, \( \delta \) is a unite lattice vector, \( N_\delta \) is the \( \delta \)-th component of \( N \) and \( \theta_\delta \) is the \( \delta \)-th diagonal value of noncommutativity matrix (we assume that \( \theta^{\mu\nu} \), is brought to the block-diagonal form), \( \theta^k \equiv \theta_1 \ldots \theta_k \). Up to the factor \( N_\delta \) this system coincides with the system of coupled rotators on the \( k \)-dimensional lattice [20], but living on a quadrant \( N_\delta \geq 0 \).

The above equations are operator ones. By passing to the oscillator basis \( \{|n\rangle\} \): \( N \ket{n} = n \ket{n} \) the action (3.6) and equation of motion (3.5) are rewritten in a simple lattice form,

\[
\ddot{u}_n = \frac{2}{\theta} [(n + 1) \sin(u_{n+1} - u_n) - n \sin(u_n - u_{n-1})] \quad (n \in \mathbb{Z}_+), \tag{3.8}
\]

\[
S = \frac{2\pi\theta}{\lambda^2} \int_{-\infty}^{+\infty} dt \sum_{n=0}^{\infty} \left\{ \frac{1}{2} (\dot{u}_n)^2 - \frac{4}{\theta} n [1 - \cos(u_n - u_{n-1})] \right\}, \tag{3.9}
\]

suitable for the analysis. If, e.g. one sets naively \( u_n = 0 \), for \( n > 0 \), one gets the sin-Gordon equation for \( u_0 \).

Let us remark that the system (3.8,3.9) has an interesting algebraic meaning. In order to see it let us rewrite eq. (3.8) in the form as follows,

\[
\dddot{u}_0 = \frac{2}{\theta} \sin(u_0 - u_1), \quad \partial_t^2 (u_1 + u_0) = \frac{2}{\theta^2} 2 \sin(u_1 - u_2), \quad \ldots \tag{3.10}
\]

\[
\partial_t^2 \left( \sum_{n=0}^{k} u_n \right) = \frac{2}{\theta} (k + 1) \sin(u_k - u_{k+1}), \tag{3.11}
\]
obtained by summing up the equations with labels from zero to some \( k \).

The conservation of the full momentum requires \( \partial^2_t (\sum_{n=0}^{\infty} u_n) = 0 \). Due to summation in eq. (3.11), the momentum is convergent only if \((u_{k+1} - u_k)\) decreases faster than \(1/k\).

It is possible to rewrite the equations (3.11) in the form as follows,

\[
\partial^2_t (v_k) = \frac{2}{\theta} (k + 1) \sin \left( \sum_l a_{kl} v_l \right),
\]

where \( v_k = \sum_{n=0}^{k} u_n \) and \( a_{kl} \) is a Cartan matrix for the \( \mathfrak{sl}(\infty) \) algebra

\[
a_{kl} = \begin{pmatrix} 2 & -1 & 0 & \ldots \\ -1 & 2 & -1 & \ldots \\ 0 & -1 & 2 & \ldots \\ \ldots & \ldots & \ldots & \ldots \end{pmatrix}
\]

Let us return back to the model (3.8), (3.9). As one can see, the equations of motion possess following static solutions,

\[
u_{\text{vac}}^n = \pi m_n,
\]

where \( m_n \) are integers. Solutions with all \( m_n \) even give true (stable) vacua of the model, while the presence of odd \( m_n \) corresponds to excitations over these vacua.

Let us note, that the r.h.s of the eq.(3.8) is lattice analog of an elliptic operator, i.e. any static solution to the eq (3.8) reduces to (3.14).

However, in the case of “spherical symmetry” one is justified to consider solutions with punched point at the origin. This eliminates the first equation from the system (3.8). The remaining equations look as follows,

\[
\frac{2}{\theta} \left[ n \sin(u_n - u_{n-1}) - (n + 1) \sin(u_{n+1} - u_n) \right] = 0, \quad n = 1, 2, \ldots
\]

The general solution to eq. (3.15) is given by,

\[
u_n = u_0 + \sum_{k=1}^{n} (-1)^{m_k - m_{k-1}} \arcsin \left( \frac{s_1}{k} \right) + \pi m_n,
\]

where \( u_0 \), and \( s_1 \) are constants of “integration”, \(-\pi \leq u_0 \leq \pi, -1 \leq s_1 \leq 1\). Again, in the case when all \( m_n \) are even this solution provides a local minimum for the energy, i.e. a metastable state. Conversely if there are odd \( m_n \) this is an unstable state.

\[\text{However, one can find a nontrivial uniformly accelerating solution, } u_n(t) = u_n^{(0)} + (a/2)t^2, \text{ where } \dot{u}_n^{(0)} = 0.\]
The solution of the type (3.16), is the lattice analog of Coulomb potential. One can readily generalise the above solution to the case of arbitrary dimension \( p \) of the noncommutative space. Indeed, the “spherical symmetry” means that solution should depend only on the sum of all \( N_\delta, \delta = 1, \ldots, p/2 \) and it is given by,

\[
    u_n = u_0 + \sum_{k=1}^{n} (-1)^{m_k-m_k-1} \arcsin \left( \frac{(k-1)!(D-1)!}{(k+D-1)!} s_1 \right) + \pi m_n, \tag{3.17}
\]

once again, \( u_0 \) and \( s_1 \) are constants of integration.

It is worthwhile to note that due to the long range character of the Coulomb force the energies corresponding to the solutions (3.16), (3.17) diverge.

When \( \theta \to 0 \), the above solutions approach the Coulomb potential respectively in two and \( p \) dimensions. However, there are some subtleties connected with this limit which we consider in Section 5.

4. \( U \)-field on a special \( q \)-space

As we have seen above, the equations we met, include sums over an infinite tower of \( n \), which potentially may diverge. Also, if one wants to apply numerical analysis to our system one face the problem that the brute truncation of the tower by some finite \( n_f \) is inconsistent. However, one can generalise the above construction by letting fields live on a special \( q \)-space instead of noncommutative plane. This \( q \)-space (when \( q \) is \( 2n_f \)-th root of unity) can be used for a regularisation of the model, because the corresponding algebra has finite dimensional representations and approaches the algebra of the noncommutative plane for \( n_f \to \infty \).

The mentioned \( q \)-space is constructed as follows. Consider more general algebra of quantum oscillator \([17], [18]\) (which is related to the \( q \)-deformed Heisenberg algebra \([19]\)), generated by \( A \) and \( \bar{A} \),

\[
    A \bar{A} - q \bar{A} A = q^{-N}, \quad A = a \sqrt[2\theta]{\frac{[N]_q}{N}}, \quad \bar{A} = \sqrt[2\theta]{\frac{[N]_q}{N}} \bar{a}, \tag{4.1}
\]

where \([N]_q = (q^N - q^{-N})/(q - q^{-1})\), while \( a \) and \( \bar{a} \) correspond to usual oscillator. For \( q \to 1 \) we get \( A \to a \) and \( \bar{A} \to \bar{a} \).

One can, therefore, find

\[
    \bar{A}A = [N]_q, \quad A\bar{A} = [N+1]_q.
\]

Define the derivatives with respect to noncommutative coordinates, as follows

\[
    \partial_2(\cdot) = -i \sqrt{\frac{1}{2\theta}} [(A + \bar{A}), (\cdot)], \quad \partial_1(\cdot) = \sqrt{\frac{1}{2\theta}} [(A - \bar{A}), (\cdot)].
\]
For $q$ being root of unity ($q^{2n_f} = 1$) one can put $A^{n_f} = 0 = (\bar{A})^{n_f}$. The action for the quantum oscillator system ($q$ is arbitrary) is chosen in the form

$$S = -\frac{2\pi\theta}{\lambda^2} \int_{-\infty}^{+\infty} dt \times \sum_{n=0}^{\infty} \langle n | \left\{ \partial_t U_N \partial_t U_N^{-1} - \frac{1}{\theta} ([\bar{A}, U_N][A, U_N^{-1}] + [A, U_N][\bar{A}, U_N^{-1}]) \right\} | n \rangle = -\frac{2\pi\theta}{\lambda^2} \int_{-\infty}^{+\infty} dt \sum_{n=0}^{\infty} \left\{ \partial_t U_n \partial_t U_n^{-1} - \frac{2}{\theta} [n + 1]_q (U_n^{-1} U_{n+1} + U_{n+1}^{-1} U_n - 2) \right\}. \quad (4.2)$$

The equations of motions corresponding to this model can be written in the form analogous to (3.11)

$$\partial_t^2 u_0 = \frac{2}{\theta} \sin(u_0 - u_1), \quad \partial_t^2 (u_1 + u_0) = \frac{2}{\theta} 2 \sin(u_1 - u_2), \quad \ldots \quad (4.3)$$

$$\partial_t^2 \left( \sum_{n=0}^{k} u_n \right) = \frac{2}{\theta} [k + 1]_q \sin(u_k - u_{k+1}). \quad (4.4)$$

or, equivalently,

$$\partial_t^2 (v_k) = \frac{4}{\theta} [k + 1]_q \sin(a_k v_l), \quad (4.5)$$

where $v_k = \sum_{n=0}^{k} u_n$ and $a_{kl}$ is the Cartan matrix (3.13). Since $[n_l]_q = 0$ for $q^{2n_f} = 1$, the system of equations (4.3) or (4.5) will be cut for $k = n_f - 1$. In this case we have the finite chain of interaction point particles, suitable e.g. for numerical analysis.

The analog of solution (3.16) in the $q$-deformed space looks as follows,

$$u_n = u_0 + \sum_{k=1}^{n} (-1)^{m_k - m_{k-1}} \arcsin \left( \frac{s_1}{[k]_q} \right) + \pi m_n, \quad (4.6)$$

with some constants $u_0$ and $s_1$. Due to finite size of the lattice in this case this solution is a finite energy one.

5. Continuum limit and Polyakov vortices

In this section we consider $p = 4$ with nondegenerate noncommutativity matrix $\theta_{\mu\nu}$, $\mu, \nu = 1, \ldots, 4$, and no time, i.e. we assume the Euclidean signature. Without loss of generality consider $\theta_{\mu\nu}$ is block diagonal. The commutators of $x^\mu$ are given by,

$$[x^1, x^2] = i\theta_{(1)} \quad (5.1)$$

$$[x^3, x^4] = i\theta_{(2)}, \quad \theta_{(2)} > 0. \quad (5.2)$$
Let us study the model describing excitations radial in \((x^1, x^2)\) and \((x^3, x^4)\) planes. The action is given by energy corresponding to eq. (3.7) for \((p/2) = 2\),
\[
S = (2\pi \theta)^2 \frac{4}{\lambda^2 \delta \theta} \sum_n n_{\delta} (1 - \cos(u_n - u_{n-\delta})).
\] (5.3)

In the absence of time coordinate this is a purely lattice action with dimensional lattice spacing parameter equal to \((2\pi \theta)\). The factor \((2\pi \theta)^2\) in the front of the sum is the volume of the elementary cube.

Consider the partition function describing such excitations,
\[
Z = \int_{-\pi}^{\pi} \prod_n \frac{du_n}{2\pi} e^{-S}.
\] (5.4)

As it was already mentioned the action (5.3) (modulo the factor \((1/\theta_\delta n_\delta)\), describes interaction of rotators on a two-dimensional lattice \([20]\). The presence of factor \(n_\delta\), can be interpreted as the nontrivial metric background on the lattice. The exact meaning of this factor will become clear when we will take the continuum (i.e. commutative) limit.

In fact the analysis of Ref. \([20]\), applies also here. Indeed, consider the isotropic weak coupling limit \(\beta \equiv 4/(\lambda^2 \theta) \rightarrow \infty\), of the model (5.4); we set \(\theta_1 = \theta_2 = \theta\).

In this limit the main contributions to the partition function come from configurations where neighbour \(u_n\) are close modulo \(2\pi \times \text{integer}\). Following Polyakov let us introduce field \(m_{n,\delta}\) to describe this integer factor and use the trick to substitute the partition function (5.4) by
\[
Z = \sum_{\{m_{n,\delta}\}} \int_{-\pi}^{\pi} \prod_n \frac{du_n}{2\pi} \exp \left( -\frac{\beta}{2} (2\pi \theta)^2 \sum_{n,\delta} n_{\delta} (u_n - u_{n-\delta} + 2\pi m_{n,\delta})^2 \right). \tag{5.5}
\]

Using the lattice analog of the Hodge decomposition theorem \([21, 22]\) (see also \([23]\)), one can decompose the integer vector field \(m_{n,\delta}\) into gradient and vortical parts as follows,
\[
m_{n,\delta} = \alpha_n - \alpha_{n-\delta} + \tilde{n}_{\delta} (\eta_{\tilde{n}_{\delta}} - \eta_{\tilde{n}}), \tag{5.6}
\]
where the tilde refers to the dual lattice, and the factor \(\tilde{n}_{\delta}\) in the last term comes from the nontrivial metric. The part containing \(\alpha_n\) carries the gradient part while the factor \(\eta_{\tilde{n}}\) the vortical one,
\[
\sum_{\text{plaquette}} m_{n,\delta} \equiv m_{n,\delta_1} + m_{n+\delta_1,\delta_2} - m_{n+\delta_2,\delta_1} - m_{n,\delta_2} = \sum_{\delta} (2\tilde{n}_{\delta} + 1) \eta_{\tilde{n}} - \tilde{n}_{\delta} \eta_{\tilde{n}-\delta} - (\tilde{n}_{\delta} + 1) \eta_{\tilde{n}+\delta} \equiv q_{\tilde{n}}. \tag{5.7}
\]
The first line is the lattice analog of external derivative, while the second line is the lattice analog of the Laplace operator. The vorticity source living on the dual lattice is denoted as $q_{\tilde{n}}$.

Making the field redefinitions one can absorb the gradient part $\alpha_n$ into the field $u_n$, spreading its values from the interval $(-\pi, \pi]$ to $(-\infty, +\infty)$. The partition function becomes,

$$Z = \sum_{\{q_n\}} \int_{-\infty}^{+\infty} \prod_n \frac{du_n}{2\pi} \prod_{\delta} n_\delta (u_n - u_{n-\delta})^2 + 2\pi^2 \sum_{\tilde{n},\tilde{\delta}} n_\delta (\eta_{\tilde{n}} - \eta_{\tilde{n}-\delta})^2 \right) 
= Z_{Gauss} \sum_{\{q_n\}} \exp \left( -\frac{\beta}{2} (2\pi\theta)^2 \sum_{\tilde{n},\tilde{n}'} q_{\tilde{n}} \Delta_{\tilde{n},\tilde{n}'}^{-1} q_{\tilde{n}'} \right)$$

where,

$$Z_{Gauss} = \prod_n \int_{-\infty}^{+\infty} \frac{du_n}{2\pi} \exp \left( -\frac{\beta}{2} (2\pi\theta)^2 \sum_{\delta} n_\delta (u_n - u_{n-\delta})^2 \right)$$

and $\Delta^{-1}$ is the inverse operator to the Laplace operator $\Delta$ given by,

$$(\Delta \eta)_n \equiv \sum_\delta ((2n_\delta + 1)u_n - nu_{n-\delta} - (n_\delta + 1)u_{n+\delta}) \right)$$

The part described by $Z_{Gauss}$ gives the “naive” weak coupling limit while the remaining part describes the gas of Polyakov vortices. Configurations with such vortices are suppressed in the limit $\beta \to \infty$. Recall that $\beta \sim 1/\theta$, therefore this is both continuum and commutative limit.

In this limit one can pass from discrete notation to continuous ones $u_n \to u(x)$, where $x^\delta = (2\pi\theta)^{n_\delta}$. Indeed, the fact that the quantity $u_n - u_{n-\delta}$ is small allows to do this. In these notations the action for the field $u$ becomes,

$$S_{cont} = \frac{1}{\lambda^2_{cont}} \int d^2x \left( x^1(\partial_1 u)^2 + x^2(\partial_2 u)^2 \right)$$

which after the change of coordinates, $x^\delta \to r^\delta = \sqrt{x^\delta/(2\pi)}$, looks like four-dimensional action for the excitations which are radial in the planes (1,2) and (3,4),

$$S_{cont} = \frac{1}{\lambda^2_{cont}} \int 2\pi dr^1r^1 2\pi dr^2r^2 \left( (\partial_{r^1} u)^2 + (\partial_{r^2} u)^2 \right)$$

where $r^1$ and $r^2$ play the rôle of radii in the planes (1,2) and (3,4) respectively.

In the weak coupling limit the the configurations with vortices enters with a factor $\exp(-\beta \times \text{constant})$, and are exponentially suppressed. In the strong coupling limit the rôle of vortices become important.

\footnote{Remember that $x^\delta \geq 0$.}
6. Discussions

In this paper we considered noncommutative charged tachyonic field. We have shown, that the vacuum dynamics of this field is described by the noncommutative $U$-field.

The model under consideration exhibits a tight relation to conventional lattice models. The similar relation was met also in the IKKT model, which is closely related to the noncommutative (super)Yang–Mills model [24], where it was shown the fermionic doubling, a phenomenon well known on the lattice.

So far, we considered both classical solutions and partition function for excitations which possess the noncommutative analog of spherical symmetry.

We have shown, that the system of these excitations is equivalent to one of rotators on an inhomogeneous lattice. This system has a reach structure of vacua. The limit of small noncommutativity corresponds to the weak coupling limit for the rotators. Thus, in the case of four Euclidean dimensions, this limit yields a free scalar field surrounded by the gas of exponentially suppressed vortices. As the noncommutativity parameter increases the vortex gas become more important, which may signal phase transitions. Since this corresponds to the string limit, perhaps the vortices can be identified with fundamental strings.

It is interesting to note that, with departing the origin the effective interaction weakens regardless how strong it was at origin. Therefore, far enough from origin one always has weak coupled regime, which means that the vortices cannot depart far from there.

We analysed the radial part of the noncommutative sigma model. It would be interesting to extend this analysis also to the noncommutative analogs of spherical harmonics (of course, if one succeed to define them).

Also, in the light of a recent paper [25], the Higgs mechanism may play some important rôle in the vacuum structure of the string field theory, which in the low energy limit reduces to the noncommutative Higgs model considered in Ref. [26, 14], to which our model is relevant.

Acknowledgments

We are grateful to A. Pashnev, S. Sergeev and K. Zarembo for helpful discussions. Work of A.P.I. was supported by RFBR grant # 00-01-00299, work of C.S. by RFBR grant # 99-01-00190, INTAS grant # 950681, and Scientific School support grant 96-15-0628, and M.T. was supported in part by the RFBR grant # 99-02-18417.
