Abstract

Classical swine fever virus (CSFV) causes a broad range of disease in pigs, from acute symptoms including high fever and hemorrhages, to chronic disease or unapparent infection, depending on the virus strain. CSFV belongs to the genus Pestivirus of the family Flaviviridae. It carries a single-stranded positive-sense RNA genome. An internal ribosomal entry site (IRES) in the 5’ untranslated region (UTR) drives the translation of a single open reading frame encoding a 3898 amino acid long polypeptide chain. The open reading frame is followed by a 3’ UTR comprising four highly structured stem-loops. In the present study, a synthetic RNA composed of the 5’ and 3’ UTRs of the CSFV genome devoid of any viral coding sequence and separated by a luciferase gene cassette (designated 5’UTR-Luc-3’UTR) triggered apoptotic cell death as early as 4 h post-transfection. The apoptosis was measured by DNA laddering analysis, TUNEL assay, annexin-V binding determined by flow cytometry, and by analysis of caspase activation. Contrasting with this, only trace DNA laddering was observed in cells transfected with the individual 5’ or 3’ UTR RNA; even when the 5’ UTR and 3’ UTR were co-transfected as separate RNA molecules, DNA laddering did not reach the level induced by the chimeric 5’UTR-Luc-3’UTR RNA. Interestingly, RNA composed of the 5’UTR and of stem-loop I of the 3’UTR triggered much stronger apoptosis than the 5’ or 3’ UTR alone. These results indicate that the 5’ and 3’ UTRs act together in cis induce apoptosis. We furthered obtained evidence that the UTR-mediated apoptosis required double-stranded RNA and involved translation shutoff possibly through activation of PKR.

Introduction

Classical swine fever virus (CSFV), belonging to the genus Pestivirus in the Flaviviridae family, is the causative agent of classical swine fever (CSF), a highly contagious disease that causes serious economic losses to the pig industry. The disease severity is dependant on the virus strain and the age of pigs. Depletion of lymphocytes is the most significant immunopathological consequence of acute CSFV infection that is attributed to an induction of apoptosis in non-infected bystander cells, possibly via the action of tumor necrosis factor (TNF)-α or interferon (IFN)-α,β,γ [1,2,3].

CSFV is an enveloped virus with a genome consisting of single-stranded, positive-sense RNA of approximately 12.3 kb [4]. The RNA genome carries a single large open reading frame flanked by a 5’ and a 3’ untranslated region (UTR). The open reading frame encodes a 3898-amino acid polypeptide which is processed into 12 mature proteins NP*, E*, C, E2, E1, E2, 2p7, NS2, NS3, NS4A, NS4B, NS5A and NS5B by viral and host proteases [5].

The 5’ and 3’ UTR of CSFV RNA are 374 and 230 nucleotides in length, respectively. The sequences of the 5’ UTR show a high degree of conservation among the Pestiviruses CSFV, Bovine viral diarrhea virus (BVDV) and Border disease virus (BDV). The 5’ UTR forms three structural domains and a pseudoknot with the sequence downstream of the initiation codon, and functions as an internal ribosome entry site (IRES) to allow the initiation of cap-independent translation [6,7,8]. It has been shown that the IRES of CSFV recruits the 40 S ribosomal subunit but none of the known initiation factors [7].

In eukaryotes, the poly(A)-binding protein (PABP) and eukaryotic initiation factor 4G (eIF4G) bind to the 3’-poly(A) tail and the 5’-terminal cap, respectively, to form a circular structure. This strategy enhances translation efficiency by recycling ribosome for successive rounds of translation [9,10]. Similar phenomenon was observed in some RNA viruses such as Hepatitis C virus (HCV) [11]. Circularization of cellular mRNA is mainly mediated by the recruitment of protein factors, by RNA-protein and protein-protein interactions to bridge the 5’ and the 3’ UTRs [12]. HCV uses complementary sequences to form loops or motifs at both ends of its RNA genome, which enables RNA circularization and facilitates translation independent from proteins [13]. Very recently, we demonstrated that the 3’ UTR of CSFV regulates the IRES-dependent translation [14]. In the absence of the 3’ UTR, the translation of a reporter gene was dramatically decreased. The addition of the stem-loops (SL) 2 and 3 (SLII and SLIII) of the 3’ UTR upregulated the translation...
of reporter gene, whereas moving SLI to the end of SLII and SLIII downregulated translation. While studying the effect of the CSFV UTRs on regulation of translation, unexpected cell death was observed in cells transfected with RNA composed of CSFV 5’ and 3’ UTRs. Therefore, the present study was aimed at identifying the requirements of the CSFV UTR to trigger apoptosis, and at exploring the possible mechanisms involved.

Materials and Methods

Cells and Viruses

Cells were obtained from Bioresource Collection and Research Center/Food Industry Research and Development Institute of Taiwan. Rabbit kidney 13 (RK-13) cell line (BCRC 60010), HeLa cells (BCRC-60005), and Madin-Darby canine kidney (MDCK) cell line (BCRC 60004) were grown in Dulbecco’s modified eagle medium (DMEM); Porcine kidney 15 (PK-15) cell (BCCR 60067), PK-15 cells constitutively expressing CSFV Npro protein fused to one of the four stem loops (i.e. SLI, SLII, SLIII, and SLIV) in vitro DNA templates for in vitro transcription were produced by

Generation of plasmids or DNA fragments for RNA preparation

The plasmid pALD/L/A contains sequences of 5’ and 3’ UTRs of CSFV [14]. This plasmid was used as template for generation of 5’UTR-Luc-3’UTR (the luciferase gene flanked with the 5’ and 3’ UTRs of CSFV) and 5’-Luc RNA (the luciferase gene with 5’ UTR of CSFV). The plasmid (pUC18-ALD-3’UTR) containing the 3’UTR was generated by insertion of the blunt-ended 3’UTR fragment amplified by PCR using the forward primer CSFV ALD 5’-CCCGGGATCTGGA; the T7 promoter sequences underlined), and reverse primer ALD 5’-TAGGGTCC-3’ (indicating the T7 promoter sequences underlined), and reverse primer ALD 5’-GTACAGCAGCTATATAGGGT-3’ into pUC18 plasmid.

DNA templates for in vitro transcription were produced by digestion of the appropriate plasmid with restriction enzymes or amplified by PCR. For instance, digestion of pALD/L/A with Sse8387I for 5’UTR-Luc-3’UTR RNA and AgeI for 3’UTR RNA, digestion of pUC18-ALD-3’UTR with BamHI for 3’UTR, digestion of SP6Luc plasmid (Promega, Madison, WI, USA) with XhoI for control luciferase RNA were performed. For in vitro transcription of RNA containing the 5’UTR-luciferase fused to one of the four stem loops (i.e. SLI, SLII, SLIII, and SLIV) of 3’UTR, templates were generated by PCR from plasmid pALD/L/SLI, pALD/L/SII, pALD/L/SLIII, and pALD/L/SLIV [14], using a universal forward primer (5’-GAGCGTCTTAA-GAAACCATTATTATC) and the reverse primers: SLI (5’-CTTATT AAAATTTGATGTGATGGGTGTT, SLII (5’-TAAATAAATAATGATGAT), SLIII (5’-CTGTTAAAAATGATGTGATGGGTGTT, SLIV (5’-TGGTTAACCAAGCGGTAGCGGGCTCAGAT), respectively.

In vitro transcription

Five micrograms of linearized DNA was transcribed in vitro in a 50 μl reaction containing 150 U of T7 RNA polymerase (or SP6 polymerase for generation of luciferase RNA) (Promega), 40 mM Tris-HCl pH 8.0, 8 mM MgCl₂, 2 mM spermidine-(HCl)₃, 10 mM dithiothreitol, 1 mM NTPs, at 37°C for 2 h. DNA template was removed by RNase-free DNase I treatment, and followed by a phenol/chloroform extraction and ethanol precipitation. RNAs were resolved in 1.2% agarose gel and RNA quality was measured by densitometry.

DNA ladderizing assay

Approximately 3–4×10⁵ cells/well were seeded in 12-well plates with appropriate medium. The culture was replenished the next day before transfection with fresh medium lacking FBS and penicillin/streptomycin. Cells were transfected 0.625 μg RNA/well (unless otherwise stated) using Lipofectamine 2000 transfection reagent (Invitrogen, Carlsbad, California, U.S.A.) according to the manufacturer’s instructions. Harvested cells were lysed with buffer containing 0.25% EDTA and 0.2% Triton X-100. The cell lysate was then treated with RNase A (70 μg/ml) at 37°C for 1 h followed by protein kinase K (150 μg/ml) at 50°C for 1 h. Subsequently, the cell lysate was extracted with chloroform (once) and phenol/chloroform (twice). After centrifugation, the aqueous phase containing chromosomal DNA was transferred to a new tube and precipitated with ethanol, air dried and dissolved in 50 μl of deionized water. The DNA samples were quantified by NanoVue Plus spectrophotometer (GE Healthcare Life Sciences).

Detection of apoptotic cells by Hoechst staining and TUNEL assay

PK-15 cells seeded in 12-well plate were transfected with luciferase or CSFV RNAs. 18 h post-transfection, cells were fixed with 4% paraformaldehyde for 10 min, washed with PBS, and incubated with 2 μg/ml of Hoechst 33342 (Sigma-Aldrich, St. Louis, MO, USA) for 1 min. The morphology of cells was observed with fluorescence microscopy.

For TUNEL staining, PK-15 cells at density of 1.5×10⁵ cells/well were seeded onto 1.3 mm coverslips in 24-well plates and were transfected with luciferase or CSFV UTR RNAs. At 4, 8, and 18 h post-transfection, cells were washed twice with phosphate-buffered saline (PBS) and then fixed with 4% paraformaldehyde. TUNEL staining was performed with an in situ cell death detection kit (Roche Applied Science, Mannheim, Germany), and observed with fluorescence microscopy.

Flow cytometric analysis of apoptosis by FITC-annexin V binding assay

PK-15 cells seeded in 12-well plate at density of 4×10⁵/well were transfected with either luciferase or CSFV UTR RNA (0.625 μg/well) and detection of annexin V was conducted using BD Pharmingen FITC Annexin V Apoptosis Detection Kit I. Briefly, cells were harvested by trypsinization 18 h post-transfection, washed with PBS and resuspended in Binding buffer at a density of 1×10⁶/ml. Cells (1×10⁵) were then incubated with 5 μl of in buffer containing FITC annexin V and propidium iodide (PI) followed by flow cytometric analysis.

Measurement of DNA fragmentation by ELISA

PK-15 cells seeded in 12-well plate were pre-treated with 100 μM of pan-caspase inhibitor Z-VAD-FAM (Calbiochem, Cat. 627610) or DMSO (as solvent control) for 3 h followed by RNA transcription as described previously. DNA fragmentation levels were measured by ELISA using Cell Death Detection ELISA-PLUS kit (Roche Applied Science) 18 h post-transfection.
Luciferase activity assay
Approximately 4 × 10^5 of RK cells were first seeded into 12-well plates and then were grown to 90% confluence. Plasmid p2Luc (0.5 μg) alone, or in combination with 0.05 pmole of CSFV 5’UTR-Luc-3’UTR, 5’ UTR, or 3’ UTR RNA diluted with 100 μl of Opti-MEM were cotransfected into RK cells using Lipofectamine (Invitrogen) according to the manufacturer’s instruction. Cells were harvested 7 h post-transfection for reporter assay. Briefly, transfected cells were washed with PBS, and then lysed with 150 μl of lysis buffer followed by a freeze-thaw process. After a centrifugation at 13,000 × g for 3 min, 20 μl of lysate was mixed with 100 μl of Luciferase Assay reagent (Promega, Cat. E2810), and the firefly luciferase activity was measured by a luminometer (FLUOstar OPTIMA, BMG Labtech, Ortenberg, Germany).

Western blot analysis
Lysate of RNA transfected cells were separated by 15% SDS-PAGE and electrotransferred to nitrocellulose membrane using Mini Protein III equipment (BioRad, Life science Research Products, CA, USA). The filter was blocked with PBS-T buffer (0.02 M phosphate, 0.15 M NaCl, 0.05% Tween-20) containing 5% skim milk powder at room temperature for 1 h and probed with 1:1,000 diluted first antibody (Cell Signaling Technology, Inc., Danvers, MA, USA), i.e. rabbit anti-cleaved Caspase-3 (Asp175, #9661B) antibody, mouse anti-eIF-2α (#L37A5), rabbit anti-phospho-eIF-2α (#ab32157, abcam, Cambridge, UK), or mouse anti-β-actin (from GeneFex Inc, Irvine, CA, USA) at 4°C for overnight. After several washes with PBS, the membrane was then incubated with the secondary antibody, goat anti-rabbit (or mouse) IgG conjugated with horseradish peroxidase (HRP), then incubated with the secondary antibody, goat anti-rabbit (or mouse) IgG conjugated with horseradish peroxidase (HRP), diluted 1:10,000 for 1 h at room temperature. Unbound antibodies were removed by PBS washes and the signal was detected using an AEC (Red) Substrate Kit (Invitrogen).

Results
Transfection of the CSFV UTR in absence of any viral coding sequences trigger apoptosis
In a previous study addressing the translational regulation of CSFV UTRs, in vitro transcribed RNA of which the coding region of CSFV was replaced by a firefly luciferase reporter gene (designated ALD/L/A or 5’9UTR-Luc-3’UTR in the present study) was transfected into porcine kidney (PK-15) cells [14]. Unexpectedly, cell death was observed when cells were transfected with the 5’U-UTR-Luc-3’UTR RNA, which was further explored here. Apoptosis was first investigated by DNA laddering assay in the porcine kidney cells PK-15 and in the rabbit kidney cells RK-13, the two cell lines commonly used to study CSFV. As shown in Fig. 1, a DNA laddering pattern was observed in PK-15 cells transfected with 5’U-UTR-Luc-3’UTR RNA (lane 3), but not in the control transfections in absence of RNA (lane 1) or with luciferase RNA (lane 2). Similar results were obtained with RK-13 cells, as evidenced by a strong increase of the DNA laddering in the presence of 5’UTR-Luc-3’UTR RNA.

Characterization of CSFV UTR-induced cell death by terminal transferase deoxyribonucleotidyl dUTP nuclear end labeling (TUNEL) and annexin V binding assays
Apoptotic cell death induced by transfection of CSFV UTR RNA was confirmed using alternative analytical approaches to DNA laddering. With Hoechest 33342 staining, nuclear condensation was clearly enhanced in 5’UTR-Luc-3’UTR RNA-transfected cells compared to luciferase RNA-transfected cells (Fig. 2A and D). A clear increase in the number of floating dead cells was observed starting 8 h after transfection (data not shown). Using the TUNEL assay, apoptosis was detected in numerous cells transfected with 5’UTR-Luc-5’UTR RNA as early as 4 h post-transfection (Fig. 2C). There was however no further increase in the number of apoptotic cells at 8 h (Fig. 2E) and 18 h (Fig. 2F) after transfection. This might be due to the loss of cells undergoing apoptosis at late times after transfection. Apoptosis was also monitored by flowcytometry by detecting the exposure of phosphatidylserine residues on the outer plasma membrane through binding of fluorescein isothiocyanate (FITC)-conjugated annexin-V. In parallel, dead cells were monitored by propidium iodide (PI) incorporation (Fig. 2G). Consistent with the other assays, a statistically significant 2.3 (±0.098) fold increase in apoptosis was observed 16 h post-transfection in cells transfected with the CSFV UTR RNA 5’UTR-Luc-3’UTR compared with control Luciferase RNA (Fig. 2H).

CSFV UTRs triggers apoptosis in a caspase-dependent manner
Apoptosis is initiated by the activation of a number of caspases [17]. The pan-caspase inhibitor Z-VAD-FMK was employed to further confirm CSFV UTR-mediated programmed cell death. As shown in Fig. 3A, DNA laddering was observed in CSFV 5’UTR-Luc-3’UTR-transfected cells treated with DMSO (solvent control), whereas it was blocked by the addition of 100 μM of Z-VAD-FMK. However treatment with lower a concentration (20 μM) of Z-VAD-FMK did not effectively inhibit the DNA laddering. Caspase-dependent apoptosis was confirmed with TUNEL ELISA. Addition of Z-VAD-FMK significantly decreased the TUNEL signal (Fig. 3B), consistent with the previous results. As caspase-3 is the executioner of apoptosis, the activation of caspase 3 was determined by Western blot analysis. Cleavage of caspase 3 was observed in cells transfected with CSFV 5’UTR-Luc-3’UTR.
RNA, but not in the control transfections (Fig. 3C). Collectively, DNA laddering, TUNEL assay, formation of apoptotic bodies (Hoechst staining), cleavage of caspase 3, and annexin V binding demonstrate that the CSFV UTRs stimulate transfected cells to undergo apoptosis.

Efficient induction of apoptosis by CSFV UTR results from synergistic effects of the 5' and 3' UTRs in cis

Having confirmed that the CSFV UTRs could induce apoptosis, it was determined which UTR structures possessed the highest capacity to induce apoptosis. To this end, RNA composed of the two UTRs on the same molecule (5'UTR-Luc-3'UTR), of the 5'UTR or the 3'UTR alone, or of control Luc RNA were transcribed in vitro (Fig 4A) and used to transfect cells for different times and at different concentrations (Fig. 4B-C). Apoptosis was analysed by DNA laddering assay. The strongest DNA fragmentation was observed in the cells transfected with the 5'UTR-Luc-3'UTR as early as 8 h post-transfection, with an increase over time (Fig. 4B). DNA laddering was barely visible with the 5'UTR and 3'UTR RNA alone at 8 and 12 h post-transfection (Fig. 4C).

**Figure 2.** Confirmation of CSFV-UTR-triggered apoptosis using different methods. PK-15 cells were transfected with luciferase RNA (A, B) or chimeric luciferase-CSFV UTR RNA (5'UTR-Luc-3'UTR, C- F). At 4 h (C), 8 h (E), or 18 h (D, F) post-transfection, cells were processed for Hoechst 33342 staining (A, D) or TUNEL assay (B, C, E, F). The inset in panel A and D shows the cells at higher magnification. Arrowheads indicate the apoptotic bodies representing nuclear condensation (D) and the apoptotic cells (C-F). The proportion of cells undergoing apoptosis was also evaluated using an annexin V-binding assay (G). PK-15 cells were transfected with either luciferase RNA or 5'UTR-Luc-3'UTR RNA. Annexin-V-FITC/PI flow cytometry analysis was performed at 18 h post-transfection. Q4-1 indicates the number of cells undergoing early apoptosis. The experiments were done in triplicates and the mean value of Q4-1 was plotted (H). Compared with cells transfected with control RNA, apoptosis increased 2.3 (±0.098) fold (P value < 0.0001) in cells transfected with CSFV UTR RNA.

doi:10.1371/journal.pone.0088863.g002
The UTRs of CSFV Trigger Apoptosis

The UTR RNA-induced apoptosis is mediated by double-stranded RNA, independently of the triphosphate moiety

The double-stranded RNA (dsRNA) generated during BVDV infection induces apoptosis that contributes to viral cytopathogenicity [18]. In order to examine whether the double-stranded RNA structures of the CSFV UTR elements were sufficient to induce apoptosis in transfected cells, in vitro transcribed 5′UTR-Luc-3′ UTR RNA was treated with RNase I or RNase III to degrade single or double-stranded RNA, respectively. Cells transfected with mock-treated or RNase I-treated RNA induced DNA fragmentation, while RNase III treatment prevented apoptosis induction (Fig. 5A), indicating that the apoptosis is induced by dsRNA structures (the stem-loops in the UTRs or the IRES structures) (Fig. 4C). Altogether, these results indicate that an intra-molecular interaction of SLI of the 3′ UTR with 5′ UTR is required for the induction of apoptosis CSFV UTR structures.

SLI of the 3′ UTR together with the 5′ UTR function in cis to induce apoptosis

For HCV and CSFV, it was reported that the interaction of the respective 5′ UTR containing the IRES structure with the 3′ UTR 5′BSL3.2 or SLI-IV of HCV or CSFV respectively, regulated viral protein translation [11,14]. Similarly, the interaction of the 5′ and 3′ UTRs may also form structures or complexes that induce apoptosis. The data above suggests that CSFV UTR-induced apoptosis results from a cross-talk between the 5′ UTR and the 3′ UTR in cis. Therefore it was investigated which part of the 3′ UTR needs to be associated with the 5′ UTR on the same molecule to induce apoptosis. To this end, four plasmids were constructed to produce RNA containing 5′-Luc with 3′-terminal fusion of either of the individual SL sequences SLI, -II, -III, or -IV. The different RNA was synthesized in vitro and their capacity to trigger apoptosis were analysed in PK-15-cells. Only the transfection of the 5′-Luc-SLI RNA induced clear DNA fragmentation (Fig. 4D). Altogether, these results indicate that an intra-molecular interaction of SLI of the 3′ UTR with 5′ UTR is required for the induction of apoptosis CSFV UTR structures.

Transfection of viral UTRs represses host cell translation

Since dsRNA can trigger apoptosis through activation of PKR, resulting in the inhibition of translation initiation [20], it was investigated whether CSFV UTR-induced apoptosis caused
translation shutoff. Translation of cellular proteins was monitored using a luciferase reporter gene assay. Considering the fact that the onset of apoptosis might interfere with the interpretation of the dsRNA-mediated effects on protein expression, minimal quantities of UTR RNA (0.05 pmole) were used in this assay, and the reporter gene expression was detected before the onset of cell death (i.e. at 7 h post-transfection). In the presence of 5'9UTR-Luc-3'9UTR, luciferase activity was barely detectable (Fig. 5C). Interestingly, the severity of apoptosis paralleled with the level of translation inhibition. In order to further determine whether the shutoff of protein synthesis is due to the activation of PKR signalling, eIF-2α phosphorylation was analysed. As shown in Fig. 5D, the level of eIF-2α phosphorylation was much higher in cells transfected with 5'9UTR-Luc-3'9UTR RNA than in cells transfected with control Luc RNA, indicating the correlation of CSFV UTR RNA-induced apoptosis with shutoff of translation.

Apoptosis triggered by CSFV UTR structures is not suppressed by Npro

It was shown that the viral nonstructural protein Npro can suppress apoptosis induced by the synthetic dsRNA pIpC in porcine kidney cell SK-6 [15,21]. Based on this, we explored whether Npro can inhibit CSFV UTR RNA-mediated apoptosis. To this end, PK-15 cells or PK-15 cell clones stably expressing Npro-GFP or GFP alone described previously [15] were transfected with 5'9UTR-Luc-3'9UTR and control RNA. No obvious difference in DNA laddering induced by 5'UTR-Luc-3'UTR RNA than in cells transfected with control Luc RNA, indicating the correlation of CSFV UTR RNA-induced apoptosis with shutoff of translation.

**Discussion**

There are several lines of evidences indicating that CSFV infection induces apoptosis in lymphocytes directly and indirectly [1,2,22]. Stimulation of pro-inflammatory cytokines (e.g. TNF-α) and viral NS3 expression have been proposed to be involved in the induction of apoptosis and pathogenicity of classic swine fever [1,23]. In the context of BVDV infection, apoptosis was attributed to dsRNA structures formed during viral RNA replication. The level of dsRNA was positively related to cytopathogenicity of BVDV [18]. In this report we show for the first time that CSFV UTR RNA devoid of any viral proteins can trigger apoptosis. Internucleosomal DNA fragmentation, visible as DNA laddering pattern in gel electrophoresis, is a major marker of apoptosis. However DNA laddering is not detectable in all cell types undergoing apoptosis, and is also not necessarily associated with apoptosis in certain cell types [16,24,25]. For these reasons, apoptosis mediated by CSFV UTR RNA was also investigated by several independent methods, including TUNEL assay, formation of apoptotic bodies (Hoechst staining), and annexin V binding. Furthermore, as the programmed cell death is executed by a hierarchy of activated caspases [26], the involvement of caspases was also examined. DNA fragmentation was reverted by treatment with the pan-caspase inhibitor zVAD-FMK, and processing of caspase-3, the effector caspase, was detected in cells transfected with CSFV UTR RNA.
Virus-induced apoptosis and type I IFN synthesis are early host defence mechanisms against viruses that may be triggered and executed through a common pathway [27]; in this context, dsRNA is an important viral trigger that can activate PKR, leading to apoptosis through inhibition of translation in virus-infected cells. In the present study, apoptosis was detected when CSFV UTR RNA was delivered by transfection, indicating that intracellular CSFV UTR RNAs can trigger apoptosis. Furthermore, the severity of apoptosis correlated with the degree of translation inhibition as evidenced by reporter assay and status of eIF-2α phosphorylation (Fig 5C, D). It is very likely that the shutoff of reporter gene expression and induction of apoptosis were both triggered by dsRNA molecules. This was supported by the fact that transfection of 5′-UTR-Luc-3′UTR RNA treated with RNase I which degrades single-stranded RNA and leaves double-stranded RNA intact, induced DNA fragmentation to a similar extent than untreated 5′UTR-Luc-3′UTR RNA. Accumulation of dsRNA is found in cells infected with ssRNA or dsRNA viruses as well as DNA viruses [28,29]. The dsRNA structures result typically from duplexes of complementary strands formed during replication and transcription.

Figure 5. UTR RNA-induced apoptosis is mediated by double-stranded RNA and independent on the triphosphate moiety. (A) Double-stranded structures contribute to the UTR RNA-triggered apoptosis. PK-15 cells were left untreated (mock), or transfected with in vitro transcribed untreated (−), RNaseH-treated (III), or RNase-treated (I) 5′UTR-Luc-3′UTR RNA (5′-Luc-3′) for 16 h prior to DNA laddering assay. (B) PK-15 cells were mock-transfected (mock), or transfected with in vitro transcribed luciferase RNA (Luc), or with calf intestinal phosphotase-treated (+) or untreated (−) 5′UTR-Luc-3′UTR RNA (5′-Luc-3′) for 16 h prior to DNA laddering assay. M: DNA size marker. (C) The degree of apoptosis correlates with the level of suppression of translation. PK-15 cells were transfected with the p2luc reporter plasmid (0.5 μg) alone, or in combination with 0.05 pmole of 5′UTR, 5′UTR-Luc-3′UTR (5′-Luc3′), 3′UTR, or control firefly luciferase (Luc) RNA. The expression of Renilla luciferase (from p2luc plasmid) was quantified 7 h post-transfection. (D) Activation of PKR is responsible for the shutoff of protein synthesis. Total protein of mock-transfected PK-15 cells (lane 1) or of cells transfected with Luc RNA (lane 2) or 5′UTR-Luc-3′UTR RNA (lane 3) was resolved by SDS-PAGE. The presence of phosphorylated eIF-2α (eIF-2α–Pi) was determined by Western blot analysis.

Figure 6. Apoptosis triggered by 5′UTR-Luc-3′UTR RNA is not inhibited by the viral Npro protein. PK-15 cells stably expressing Npro-GFP or GFP, and the parent PK-15 cells were transfected with in vitro transcribed 5′UTR-Luc-3′UTR RNA (lane 1), luciferase RNA (lane 2), or mock transfected (lane 3) or left untreated (lane 4). After 23 h, total DNA was harvested for the DNA laddering assay. M: standard DNA marker.

doi:10.1371/journal.pone.0088863.g006

Virus-induced apoptosis and type I IFN synthesis are early host defence mechanisms against viruses that may be triggered and executed through a common pathway [27]; in this context, dsRNA is an important viral trigger that can activate PKR, leading to apoptosis through inhibition of translation in virus-infected cells. In the present study, apoptosis was detected when CSFV UTR RNA was delivered by transfection, indicating that intracellular CSFV UTR RNAs can trigger apoptosis. Furthermore, the severity of apoptosis correlated with the degree of translation inhibition as evidenced by reporter assay and status of eIF-2α phosphorylation (Fig 5C, D). It is very likely that the shutoff of reporter gene expression and induction of apoptosis were both triggered by dsRNA molecules. This was supported by the fact that transfection of 5′UTR-Luc-3′UTR RNA treated with RNase I which degrades single-stranded RNA and leaves double-stranded RNA intact, induced DNA fragmentation to a similar extent than untreated 5′UTR-Luc-3′UTR RNA. Accumulation of dsRNA is found in cells infected with ssRNA or dsRNA viruses as well as DNA viruses [28,29]. The dsRNA structures result typically from duplexes of complementary strands formed during replication and transcription.
transcription as well as from secondary structures within sRNA molecules [30]. In response to virus infections, type I interferons (IFNs) can be activated through the engagement of viral danger signals such as dsRNA and sRNA sensed by Toll-like receptors (TLRs) and RIG-like helicases (RLHs) [31]. RIG-I detects cytoplasmic viral dsRNA or 5’-triphosphorylated sRNA leading to activation of signalling pathways that mediate type I IFN production. In the present study, DNA fragmentation induced by 5’-UTR-Luc-3’-UTR RNA was independent of the presence of triphosphates (Fig. 3B), which does however not exclude the engagement of RIG-I.

Although some viruses use apoptosis to destroy infected cells allowing the virus to spread, excessive cell death would prevent the progression of virus infection. Hence, viruses evolved strategies to subvert or delay the onset of cell death following infection. Several reports show that Pestivirus counteract pro-apoptotic effects [21,32,33]. For CSFV it was shown that the viral nonstructural protein N\textsuperscript{pro}, the first viral protein encoded by the viral genome [34], plays a significant role in suppressing the plpC-induced apoptosis in the porcine kidney cell line SK-6 [15,21]. Very recently the inhibition of apoptosis by N\textsuperscript{pro} was proposed to function through the anti-apoptotic protein HAX-1 (HS-1-associated protein X-1) that interacts with the C terminus of N\textsuperscript{pro} [35]. Interestingly, in the present study, apoptosis induced by the CSFV UTR RNA was not suppressed by N\textsuperscript{pro} (Fig 6). This suggests that other viral protein(s) are required for efficient inhibition of apoptosis mediated by CSFV UTR RNA. There is evidence that E\textsuperscript{NS2}, a viral surface protein, does also contribute to inhibition of apoptosis mediated by CSFV UTR RNA. There is evidence that E\textsuperscript{NS2}, a viral surface protein, does also contribute to CSFV-mediated inhibition of apoptosis: CSFV repressed caspase 3 activation in plpC-treated cells, which was reverted in the absence of either N\textsuperscript{pro} or E\textsuperscript{NS2} [36]. Furthermore, non-structural protein NS2 was shown to interfere in the apoptotic process under certain circumstances. Stable expression of CSFV NS2 protein upregulated the expression of the anti-apoptotic protein Bcl-2 that contributes to resistance to apoptosis induced by the proteasome inhibitor MG132 in swine umbilical vein endothelial cell line [37]. It was proposed that CSFV infection blocks apoptotic signalling at multiple levels, including at the caspase-3 and the mitochondrial checkpoints through the action of different viral proteins [36].

Whether these proteins would work synergistically in suppressing CSFV UTR RNA induced-apoptosis requires further investigation.

Transfected RNA carrying both, the 5’ and 3’ UTR on the same RNA molecule induced much severe apoptosis than the 5’UTR or the 3’UTR alone at the same molarity (Fig. 4B). These results suggest that an interaction between the 5’UTR and the 3’UTR is required in cis for the induction of apoptosis. SLI of the 3’UTR played a major role in this context (Fig 4C). This is related to our previous results showing that SLI of the CSFV 3’UTR repressed expression of a reporter gene, which was further mapped to the hexamer CGGCCG of the 3’ end of SLI possibly forming a base pair with the sequence in the IRES III1 of 5’ UTR, the 40 S ribosomal subunit binding site [14]. These results support a possible interaction of SLI of 3’UTR with 5’UTR RNA being involved in the induction of apoptosis.

In summary, it was shown by several independent experimental approaches that the CSFV UTR RNA can trigger apoptosis in transfected cells. Importantly, to induce apoptosis the 5’ and 3’ UTR RNA have to function together in cis but not in trans, possibly via interaction of the 5’UTR with SLI of the 3’ UTR. In this context, the double-stranded structures of the CSFV UTRs are sufficient to trigger apoptosis. Finally, the UTR mediated apoptosis is related to suppression of translation involving the phosphorylation of eIF-2a.

Acknowledgments

We thank Dr. Nicolas Ruggli for providing data with the cell line expressing N\textsuperscript{pro}, for helpful advice and for critical reading of the manuscript.

Author Contributions

Conceived and designed the experiments: WLH CLC CHT. Performed the experiments: CLC SWH CCW IHC YPS. Analyzed the data: WLH CLC SWH CCW IHC MN CHT. Contributed reagents/materials/analysis tools: CLC SWH CCW IHC MN YPS. Wrote the paper: WLH CLC CHT.
