Background. Special regulatory role of eicosanoids has been postulated in aspirin-induced asthma. Objective. To investigate effects of aspirin on exhaled breath condensate (EBC) levels of eicosanoids in patients with asthma. Methods. We determined EBC eicosanoid concentrations using gas chromatography/mass spectrometry (GC-MS) and high-performance liquid chromatography/mass spectrometry (HPLC-MS²) or both. Determinations were performed at baseline and following bronchial aspirin challenge, in two well-defined phenotypes of asthma: aspirin-sensitive and aspirin-tolerant patients. Results. Aspirin precipitated bronchial reactions in all aspirin-sensitive, but in none of aspirin-tolerant patients (ATAs). At baseline, eicosanoids profile did not differ between both asthma groups except for lipoxygenation products: 5- and 15-hydroxyeicosatetraenoic acid (5-, 15-HETE) which were higher in aspirin-induced asthma (AIA) than aspirin-tolerant subjects. Following aspirin challenge the total levels of cysteinyl-leukotrienes (cys-LTs) remained unchanged in both groups. The dose of aspirin had an effect on magnitude of the response of the exhaled cys-LTs and prostanoids levels only in AIA subjects. Conclusion. The high baseline eicosanoid profiling of lipoxygenation products 5- and 15-HETE in EBC makes it possible to detect alterations in aspirin-sensitive asthma. Cysteinyl-leukotrienes, and eoxins levels in EBC after bronchial aspirin administration in stable asthma patients cannot be used as a reliable diagnostic index for aspirin hypersensitivity.

1. Introduction

Exhaled breath condensate (EBC) is a simple, noninvasive technique for monitoring airway inflammation. The measurement of eicosanoids in the expired breath condensate has proven to be a useful noninvasive method for the assessment and monitoring of airway inflammation in inflammatory diseases such as asthma and other pulmonary diseases [1, 2].

Eicosanoids, including prostaglandins (PGs), thromboxane A2 (TXA2), and leukotrienes (LTs), are lipid mediators involved in the pathogenesis of asthma. TXA2 is rapidly converted to thromboxane B2 (TXB2), a chemically stable metabolite. Thus, thromboxane synthesis in biological tissues has been monitored by measuring TXB2 [1, 2]. Eoxins C4, D4, and E4 (EXC4, EXD4, EXE4) are 15-lipoxygenase (15-LO) analogues of cysteinyl leukotrienes (cys-LTs). Eoxins were metabolized to eoxin E4 and detectable in EBC [3].

Another group of lipoxygenation products is 5-, 12- and 15-hydroxyeicosatetraenoic acid (5-HETE, 12-HETE, 15-HETE). Isoeicosanoids or isoprostanes are prostaglandin-like compounds produced by nonenzymatic lipid peroxidation of arachidonic acid. The 8-isoprostane is the best biomarker of oxidative stress and lipid peroxidation [1–3].

A special regulatory role of eicosanoids was postulated in aspirin-induced asthma (AIA) [4–6]. AIA is characterized by nasal polyps, persistent asthma, and aspirin hypersensitivity [4]. These nasal/sinus and bronchial syndromes with aspirin hypersensitivity have been named aspirin-exacerbated respiratory disease (AERD). Indeed, in this distinct asthma phenotype [7], observations have accumulated pointing to (1) overproduction of cysteinyl-leukotrienes (cys-LTs), which are potent proinflammatory mediators and bronchoconstrictors [4, 6, 8], (2) upon ingestion of aspirin, cys-LTs are further released in rising amounts probably from eosinophils...
and mast cells and this is accompanied by worsening of asthma symptoms [9, 10], (3) depressed prostaglandin E2 (PGE2) production by peripheral blood cells [11], nasal polyps [12, 13], bronchial fibroblasts [14], diminished EP2 receptor on the inflammatory cells, and association with EP2 gene polymorphism [15, 16], (4) aspirin-precipitated asthmatic attacks are not associated with changes in the systemic prostaglandin E2 production, it might stem from the release of PGE2 from inflammatory cells during the clinical reactions to aspirin [17], (5) both prostaglandin D2 (PGD2) and its metabolite increase after aspirin-induced bronchoconstriction suggesting that this reaction is associated with mast cell activation [18–20].

Aspirin-induced changes in the levels of eicosanoids, such as prostaglandins (PGs) and cys-LTs, have been examined in various biologic samples, such as plasma [19, 20], saliva [19], induced sputum [19, 21], nasal washing fluid [22, 23], bronchoalveolar lavage [24], and urine [9, 10, 17, 25]. So far, there are few published articles on eicosanoids in EBC in aspirin-induced-asthma patients [26–28]. These studies concentrated on baseline levels of eicosanoids in EBC independent of any steroid therapy used. Interestingly, one of these studies reported prostaglandins (PGE2, PGF2α, 9α11βPGF2α) and cys-LTs levels in breath condensates in asthmatic patients after oral aspirin challenge [28]. In the present study, we focus on exhaled breath condensate concentrations of eicosanoids following bronchial aspirin challenge, local administration of aspirin in aspirin-induced asthma patients.

The aim of this study was to evaluate the changes in wide eicosanoid spectrum concentrations in EBC during asthmatic response following aspirin inhalation. We hypothesized that the profile of eicosanoids in EBC after local aspirin administration is markedly different in aspirin-induced asthma patients as compared to asthmatics who tolerate aspirin well. These results were validated by specific analytical techniques, such as gas chromatography/mass spectrometry (GC-MS) or by high-performance liquid chromatography/mass spectrometry (HPLC-MS).

## 2. Material and Methods

### 2.1. Subjects

The study population consisted of 21 asthmatic patients sensitive to aspirin (AIA) and 23 asthmatics who tolerated aspirin well (ATA). The diagnosis of asthma was established according to GINA 2008 update. The patients’ characteristics are presented in Table 1.

The diagnosis of aspirin intolerance was confirmed by oral aspirin provocation tests, performed during 36 months preceding the study. All ATA patients occasionally used aspirin without any adverse reactions. The patients had stable asthma and their baseline FEV1 was >70% of the predicted value on the study day. None had experienced an exacerbation or a respiratory tract infection in the 6 weeks preceding the study. Nearly 70% of ATA patients had intermittent asthma, 13% mild persistent asthma, and 17% moderate persistent. In AIA group, 67% of patients had intermittent asthma, 19% mild persistent asthma, and 14% moderate persistent asthma. According to Asthma Control Test 33% of AIA patients and 26% of ATA patients had controlled asthma, and 33% and 48% had partly controlled asthma, 33% and 26% had uncontrolled asthma, respectively. In ATA group, 2 patients were current smokers and 3 exsmokers. There were 7 exsmokers and no current smokers in AIA group. The average level of FEV1 and FEV1/FVC in AIA patients was 89.9% and 73.2%, in ATA patients was 91.5% and 78.5%, respectively.

The subjects were instructed to withhold medications that decrease bronchial responsiveness prior to aspirin challenge. Short-acting β2-agonists were not used 8 hours before the challenge. Long-acting β2-agonists and theophylline were

### Table 1: Clinical characteristics of the patients.

| AIA (n = 21) | ATA (n = 23) | P |
|--------------|-------------|---|
| Age (y)      | 44.9 ± 13.96| 39.8 ± 8.71 | N.S. (0.33) |
| Female/Male  | 39 (34/58)  | 39 (32/45)  |               |
| Duration of asthma (y) | 12.36 ± 8.07 | 10.26 ± 11.33 | N.S. (0.36) |
| Inhaled steroids yes/no | 18/3 | 22/1 | N.S. (0.34) |
| Inhaled steroids (μg/d) flutikason | 616.57 ± 425.83 | 726.09 ± 667.06 | N.S. (0.93) |
| FEV1 baseline (% predicted) | 89.87 ± 10.83 | 91.45 ± 11.47 | N.S. (0.57) |
| Total IgE (IU/mL) | 90.01 (83.45 ± 95.29) | 91.3 (84.81 ± 102.1) |               |
| Total IgE (IU/mL) | 115.16 ± 111.41 | 162.86 ± 177.82 | N.S. (0.78) |
| Total IgE (IU/mL) | 76.3 (42.8 ± 158) | 66.8 (24.1 ± 179) |               |
| Skin prick test (n) positive/negative | 10/9 | 15/8 | N.S. (0.53) |
| Blood eosinophil count | 472.67 ± 295.39* | 248.22 ± 173.32* | 0.003 |

Values are expressed as mean ± SD, and median (25% and 75% percentiles).

AIA: aspirin-induced asthma.
ATA: aspirin-tolerant asthma.
Table 2: Eicosanoids values at baseline and following aspirin challenge in AIA and ATA patients. Results of eicosanoids were recalculated as parts per million (ppm) of palmitic acid (PA).

|                  | AIA (n = 21) | AT (n = 23) | P (ANOVA) |
|------------------|--------------|-------------|-----------|
|                  | Baseline     | Challenge   | Baseline  | Challenge   | After the challenge |

FEV1 was measured at 10, 20, and 30 minutes after each dose. At 0.5 hour intervals, up to the cumulative dose of 181.98 mg. Doses of 0.18, 0.36, 0.90, 2.34, 7.20, 16.2, 39.60, 115.20 mg, at aspirin and by changing the number of breaths (increasing every 30 minutes by increasing the concentration of lysine-aspirin). In patients with positive bronchial aspirin challenge (AIA), exhaled breath condensate samples were collected for wide eicosanoid spectrum (see Table 2) estimations at baseline and at the time of appearance of the bronchial symptoms (time 0). In ATA patients, whose aspirin challenge was negative, exhaled breath condensate samples were collected at baseline and 0.5 hours after the last aspirin dose, that is, when the cumulative doses of 181.98 mg was reached (time 0).

Baseline and following bronchial aspirin challenge, exhaled breath condensate eicosanoids (see Table 2) levels were measured in all subjects. The patients gave informed consent and the study was approved by the University Ethics Committee.

2.2. Study Design. The single-blind, placebo-controlled bronchial challenge test with aspirin was carried out during one day in all study patients [29]. The test began with the inhalation of 7 breaths of placebo (saline). FEV1 was measured at 10 and 20 minutes after placebo inhalation. The post-saline FEV1 obtained at 20 minutes was used as “postsaline baseline” value.

The consecutive doses of lysine-aspirin were inhaled every 30 minutes by increasing the concentration of lysine-aspirin and by changing the number of breaths (increasing doses of 0.18, 0.36, 0.90, 2.34, 7.20, 16.2, 39.60, 115.20 mg, at 0.5 hour intervals, up to the cumulative dose of 181.98 mg). FEV1 was measured at 10, 20, and 30 minutes after each dose. The challenge procedure with aspirin was interrupted, if a bronchospastic reaction occurred (FEV1 dropped ≥ 20%), or if the maximum cumulative dose of aspirin was reached. The cumulative dose of aspirin causing a 20% fall in FEV1 was calculated and recorded as PD20 (provocation dose of aspirin). FEV1 and extrabronchial symptoms were recorded at baseline, before the challenge tests, and then every 30 minutes until 6 hours after the last dose of aspirin.

2.3. Lung Function. Pulmonary function tests were performed on a flow-integrating computerized pneumotachograph (Pneumoscreen, E. Jaeger, Germany).

2.4. Exhaled Breath Condensate (EBC). EBC was collected according to ATS/ERS [1] using ECO Screen instrument of Jaeger (GmbH Hoechberg, Germany). Following tidal breathing for 15–20 min, 1–2 mL of clear fluid was collected and immediately deeply frozen.

2.5. Biochemical Assays. Exhaled breath condensate concentration of eicosanoids was measured by gas chromatography/mass spectrometry (GC-MS) and by high-performance liquid chromatography/tandem mass spectrometry (HPLC-MS2) or both; see Table 2. Results of eicosanoids were recalculated as parts per million (ppm) of palmitic acid (PA).
or expressed as picograms per milliliter (pg/mL). Detection limits for eicosanoids measurements were between 0.17 pg/mL for 12-HETE and 0.89 pg/mL for PGD₂. Intraassay coefficients of variance were less than 10% and interassay coefficients of variance were less than 15%. Accuracy of measurements were better than 98.7%. Detailed analytical procedure and deuterated standards used were described elsewhere [3, 27].

2.6. Statistical Analysis. Summary statistics were expressed as mean (M), standard deviation (SD), median (Me), and 25% and 75% percentiles. General linear model (GLM) including repeated measures analysis of variance, which takes into account the fact that the outcome measurements are repeated over time within subject was used for multiple comparisons. Logarithmic transformation was used when needed as variance stabilizing transformation. Correlation between variables was estimated with the Spearman rank order correlations. A P-value ≤ 0.05 was considered statistically significant.

3. Results

3.1. Clinical Reactions. There was no statistical difference in the clinical characteristics between patients with aspirin-induced asthma (positive aspirin challenge test), and those who tolerated aspirin well (negative aspirin challenge test) except for blood eosinophil count, Table 1. None of the patients developed symptoms after administration of placebo. In aspirin-sensitive asthmatics, bronchial reactions developed after 0.18 mg in 1 subject, after 0.36 mg in 2 subjects, after 0.9 mg in 3 subjects, following 2.34 mg in 2, after 7.2 mg in 5 subjects, after 16.2 mg in 4 subjects, following 39.6 mg in 2 subjects, and after 115.2 mg in 2 subjects. The mean cumulative dose of aspirin was 32.108 mg. All the symptoms were relieved by short-acting β₂-agonists. None of ATA patients developed any clinical symptoms following aspirin challenges.

3.1.1. Cyclooxygenase Products

Exhaled Breath Condensate Concentration of Prostanoids. At baseline (Table 2), exhaled breath condensate levels of PGD₂, such as its metabolite 9α11βPGF₂, and PGF₂α, 6-keto-PGF₁α and nonenzymatic isomer (8-iso-PGF₂), did not differ significantly between the study groups. Statistically, results did not differ dependently on the methods used (HPLC/MS/MS or GC/MS) for marking eicosanoids and results shown (ppm of PA or pg/mL).

In cases when 11-dehydro TXB₂ resulted as ppm of PA, at baseline (Table 2) and following aspirin challenge (ANOVA, \(P = 0.66\)) exhaled breath condensate level of 11-dehydro TXB₂ did not differ significantly between the study groups.

Negative correlation was founded between provocation doses of aspirin and exhaled PGD₂ and its 9α11βPGF₂, PGF₂α, 6-keto-PGF₁α, and 11-dehydro TXB₂ levels only in AIA patients.

3.1.2. Lipoxigenation Products

Exhaled Breath Condensate Concentration of Cysteinyl-Leukotriene (Cys-LTs). At baseline (Table 2), exhaled breath condensate levels of leukotrienes C₄, D₄, and E₄ did not differ significantly between the AIA and ATA groups (\(P = 0.43\), \(P = 0.22\), \(P = 0.79\), resp.).

In both study groups, following aspirin challenge, EBC level of LTC₄ decreased significantly (ANOVA, \(P = 0.003\)). No significant differences in EBC levels of LTD₄ was found in AIA and in ATA group patients (ANOVA, \(P = 0.67\)), where the level remained unchanged and at a constant. Exhaled LTE₄ after aspirin challenge increased significantly in both study groups (ANOVA, \(P = 0.03\)). However, total level of cys-LTs (the sum of LTC₄, LTD₄, LTE₄) showed no changes in either group studied. Statistically the results of cys-LTs in EBC were identical independent of units (measurement) used (ppm of PA or pg/mL).

The dose of inhaled steroid used by study patients and FEV₁ values had no effect on magnitude of the response of the cys-LTs and its duration.

Negative correlation was founded between provocation doses of aspirin and exhaled LTC₄ (\(r = -0.47\), \(P = 0.04\), LTD₄ (\(r = -0.46\), \(P = 0.04\) and LTE₄ (\(r = -0.43\), \(P = 0.05\) levels only in AIA patients.

Exhaled Breath Condensate Concentration of Leukotriene B₄. At baseline (Table 2), exhaled breath condensate level of leukotriene B₄ did not differ significantly between the AIA and ATA groups (\(P = 0.36\)).

Following aspirin administration, EBC levels of LTB₄ decreased significantly only in aspirin-sensitive patients (ANOVA, \(P = 0.03\)). No differences were observed when LTB₄ was expressed as pg/mL.

Exhaled Breath Condensate Concentration of HETE. At baseline (Table 2), exhaled breath condensate levels of 5-HETE and 15-HETE were significantly higher in AIA as compared to ATA groups (\(P = 0.03\), \(P = 0.001\), resp.). Figure 1. Following bronchial aspirin administration, EBC levels of 5- and 15-HETE (ANOVA, \(P = 0.23\)) remained unchanged in AIA (\(P = 0.37\) and \(P = 0.23\), resp.) and ATA patients.

At baseline (Table 2), exhaled breath condensate levels of 12-HETE did not differ significantly between the AIA and ATA groups (\(P = 0.13\)). Following aspirin administration, EBC levels of 12-HETE decreased significantly only in ATA group (\(P = 0.03\), due to outliers Wilcoxon Matched pairs test was used).
Figure 1: Eicosanoids’ levels in exhaled breath condensate before and after bronchial aspirin challenge. (a) 5-HETE, (b) 15-HETE, and (c) 12-HETA. AIA: aspirin-induced asthma. ATA: aspirin-tolerant asthma. B: baseline. Ch: challenge.

The dose of inhaled steroid used by patients and FEV1 values had no effect on magnitude of the response of the 5- and 15-HETE. At baseline, negative correlation was found between the doses of steroids and EBC levels of 12-HETE only in aspirin-sensitive subjects ($r = -0.45, P = 0.04$).

The dose of aspirin, had no effect on the magnitude of response of 5- and 15-HETE.

**Exhaled Breath Condensate Concentration of Eoxins.** At baseline and following aspirin challenge, exhaled breath condensate levels of eoxins C4, D4, and E4 did not differ significantly between the AIA and ATA groups (see Table 2).

At baseline and following aspirin challenge no correlation was found between provocation doses of aspirin, inhaled steroid therapy and FEV1 values, and eoxins EBC levels in aspirin-sensitive and aspirin-intolerant patients.

### 4. Discussion

In this study, we used a validated analytic platform [27, 30, 31] to analyze eicosanoids in EBC of asthmatic patients. A highly sensitive method of gas chromatography/mass spectrometry or high-performance liquid chromatography/mass spectrometry or both were used to measure spectrum of eicosanoids-nonvolatile compounds present in EBC [3, 27, 31]. Novel concepts for the standardization of EBC material measurements have been introduced to obtain characteristics of eicosanoid patterns produced by asthmatic lungs [27]. The assessment of palmitic acid content in EBC among many other methods [32] seems to be a convenient solution for compensating the “dilution factor” [3]. It has recently been demonstrated that dilution of nonvolatile compounds in water differs between the subjects by more than 1 order of magnitude and depends on ventilation mechanics [33, 34]. For that reason, in this paper, data are recalculated as parts per million of palmitic acid. For better understanding, EBC eicosanoid levels are given in both applicable units: ppm of PA (Table 2) and in pg/mL (Table 3) independently of performed assay.

The aim of this study was to compare a wide profile of eicosanoids released to the epithelial surface of the asthmatic lung in subjects with and without aspirin hypersensitivity at baseline and following bronchial aspirin challenge, most of them on chronic inhaled steroid therapy. We demonstrated for the first time exhaled eicosanoids following local administration of aspirin in aspirin-induced asthma patients.

Comparing subjects with AIA and ATA no significant differences were observed in EBC levels of cyclooxygenase pathway prostanoid products (PGD2 and its metabolite 9α,11β-PGF2α, PGF2α, 6-keto-PGF1α, and 11-dehydro TXB2) and nonenzymatic isomer (8-iso-PGF2α) in neither baseline nor after aspirin inhalation. Opposing data has been earlier reported as lower [28] and other times higher [27] baseline PGD2 metabolite, namely, 9α,11β-PGF2α, levels in EBC in AIA patients. Differences observed in this previous study between both asthma phenotypes [27] can possibly be explained by lower FEV1 values and more severe of disease in patients with aspirin hypersensitivity compared to subjects who tolerated aspirin well. Moreover, a significant predictor of decreased FEV1 was increased 9α,11β-PGF2 only in AIA which did

Median (25% and 75% percentiles).
AIA: aspirin-induced asthma. ATA: aspirin-tolerant asthma.
*P*-values < 0.05; AIA versus ATA at baseline or after the challenge.
**P*-values:
* AIA versus ATA at baseline.
*baseline versus challenge in AIA.
*baseline versus challenge in ATA.

The dose of inhaled steroid used by patients and FEV1 values had no effect on magnitude of the response of the 5- and 15-HETE. At baseline, negative correlation was found between the doses of steroids and EBC levels of 12-HETE only in aspirin-sensitive subjects ($r = -0.45, P = 0.04$).

The dose of aspirin, had no effect on the magnitude of response of 5- and 15-HETE.
not correlate in ATA subjects [27]. In our study, all patients presented comparable FEV₁ values, and most likely, similar bronchoconstricting eicosanoid levels such as PGD₂ and its metabolite. Mast cells are probably the main source of PGD₂ overproduction. Higher global production of PGD₂ metabolite 9α,11β-PGF₂ was also present in the blood and urine at baseline in AIA subjects [18, 20]. Concentration of 9α,11β-PGF₂ was not changed by the oral–systemic [28] and how indicated our data bronchial-local administration of aspirin.

Our results revealed a significant upregulation of some arachidonate lipoxygenation products in asthmatic subjects with aspirin hypersensitivity, as manifested by high baseline levels of 5-, 15-HETE in EBC. This data is consistent with the independent of aspirin hypersensitivity. Their concentrations were not changed by the bronchial aspirin challenge. Role of those eicosanoids has been recently investigated in aspirin hypersensitive patients.

The high-sensitivity eicosanoid profiling of lipoxygenation products (5-HETE, 15-HETE) in EBC makes it possible to detect alterations in asthma, especially in its distinct phenotype characterized by hypersensitivity to aspirin and other nonsteroidal anti-inflammatory drugs. Cysteinyl-leukotriene levels in EBC after aspirin challenge in stable asthma patients, not steroid naive, most probably cannot be used as a reliable and sensitive index for aspirin hypersensitivity. In stable AIA patients on chronic inhaled steroid therapy of global (urinary) rather than in local (breath condensate) production of postchallenge cys-LTs is of greater and more sensitive value for aspirin hypersensitivity. We believe that quantitate cell analysis and measurements of released eicosanoids in induced-sputum will be more applicable for that purpose.

**List of Abbreviations**

AIA: Aspirin-intolerant asthma
ATA: Aspirin-tolerant asthma
EBC: Exhaled breath condensate
GC-MS: Gas chromatography-mass spectrometry
HPLC-MS/MS: High-performance liquid chromatography-tandem mass spectrometry
COX: Cyclooxygenase
PG: Prostaglandin
9α,11β-PGF₂: PGD₂ semistable metabolite
6-keto-PGF₁α: Prostacyclin metabolite
11-dehydro-TXB₂: Thromboxane A₂ metabolite
EP₂: Prostaglandin receptor 2
LO: Lipoxygenase
HETE: Hydroxyeicosatetraenoic acid
LT: Leukotriene
Cys-LTs: Cysteinyl leukotrienes
8-iso-PGF₂α: Isoprostane F₂α
NSAIDs: Nonsteroidal anti-inflammatory drugs.
