(Dated: April 1, 2014)

The general two-higgs doublet model (2HDM) contains a rich spectrum of neutral and charged Higgs bosons, whose detection would be a clear signal of new physics. When the Higgs potential is CP-conserving, the spectrum includes a pseudoscalar mass eigenstate $A^0$, which does not couple to vector bosons at tree-level. However, fermionic loops (top and bottom mainly) induce the coupling $AV V'$ (with $V, V' = \gamma, Z$) at higher orders. We evaluate the amplitude for the decays $A^0 \rightarrow ZZ, Z\gamma, \gamma\gamma$, including a generic fermionic loop contribution, and present results on the branching ratios for 2HDM-I, II and III. Current LHC searches on heavy Higgs bosons are used as an estimate to constrain the allowed mass range for $A^0$.

PACS numbers:

I. INTRODUCTION

After many years of planning and preparation, the LHC has found evidence of a Higgs-like particle, with mass $m_H \approx 125 \sim 126$ GeV \cite{1, 2}. It is remarkable that the observed Higgs mass falls within the range preferred by the analysis of electroweak precision tests, within the Standard Model \cite{3}. Although the measured couplings point towards a SM Higgs interpretation for such particle, more data will be needed in order to determine whether this resonance belongs to the SM or to some of its extensions; in the later case its properties could deviate from the SM expectations \cite{4}.

On the other hand, the LHC has also searched for signals of new physics beyond the SM, either through the production of new particles or by looking for anomalous couplings for the SM particles \cite{3}. However, so far current LHC studies have not detected any evidence of new physics, and the resulting bounds on the associated scale has been pushed into the TeV territory \cite{4}. In fact, the weakest bounds are precisely on the search for heavy Higgs particles \cite{5, 6, 7, 8}, which are predicted in many models of new physics, including SUSY, XD, GUTs etc \cite{10, 11, 12}. Thus, searching for those Higgs particles could provide the first signal on physics beyond the SM. Furthermore, this task could be attempted now with some degree of optimism, because once the LHC has detected a scalar-like state, it seems possible that more scalars could appear in the future LHC data.

One of the simplest extensions of the SM, consists of the addition of an extra Higgs doublet, the so called Two-Higgs doublet model (2HDM), which has been widely studied in all the presentations that have been proposed (2HDM I, II, III, X, Y, etc) \cite{14}. Some interesting properties of the 2HDM include:

- A rich Higgs boson spectrum is predicted within this model, which includes three neutral degrees of freedom and one charged Higgs boson ($H^{\pm}$),
- Among the neutral states, the model predicts the existence of a pseudoscalar state $A^0$, which would be a clear sign of new physics, and whose phenomenology we are interested in,
- When the Higgs potential is CP conserving, $A^0$ is also a mass eigenstate \cite{15},
- Because of the quantum number assignments and discrete symmetries of the model, this state does not couple to vector bosons at tree-level. However, such couplings could be induced at loop level \cite{16},

In this paper, we are interested in studying the one-loop decays of the pseudoscalar $A$ into a pair of vector bosons, namely $A^0 \rightarrow ZZ, Z\gamma, \gamma\gamma$, within the context of the two-higgs doublet model (2HDM), some of these decays have been studied in effective Lagrangians context \cite{17, 18}. We shall work within the versions of the model where the Higgs sector respects CP symmetry, which could occur in 2HDM-I, II and III; in this case $A^0$ is actually a mass eigenstate. The loop amplitude for $A \rightarrow VV'$ receives contributions from heavy fermions, mainly from the top and bottom quarks.

It turns out that the fermionic contribution within 2HDM I, II, depends only on the Yukawa lagrangian parameters, which reduce in the end to $\tan \beta$ (the ratio of the vacuum expectation values, i.e. $\tan \beta = v_2/v_1$) and the fermion masses. On the other hand, within the 2HDM-III, where one assumes some texture structure for the Yukawa matrices \cite{19}, one needs to consider additional parameters, which are called $\chi_{ij}$ \cite{20}. For $i \neq j$ those couplings would induce...
Flavor Changing Neutral Currents (FCNC) mediated by the scalars, while for $i = j$ those couplings would correct the usual 2HDM predictions for the diagonal Higgs-fermion couplings. The dominant contribution to the loop amplitude in the low and moderate $\tan \beta$ ($\approx 1 - 5$) comes from the top quark. For larger values of $\tan \beta$, which seem disfavored by low energy constraints on the 2HDM, the bottom quark contribution should also be included.

The organization of this paper goes as follows: section II contains a discussion of the general 2HDM, and its limiting cases, focusing on the Higgs-fermion couplings. Section III includes a discussion of the decay amplitude for the process $A \to VV'$, written in general terms, i.e. including the most general couplings of the pseudoscalar $A^0$ with fermions; there we also present the simplified expressions for the decay widths of the decays $A^0 \to ZZ, Z\gamma, \gamma\gamma$. Then, in IV we discuss the numerical results for the branching ratios, and we identify regions of parameters where those decays show a large branching ratio. Then, we study the constraints that current searches for heavy Higgs bosons at LHC could impose on the parameters of the model. This is done through the evaluation of the signal strengths ($R_{ZZ}$), which are used as an estimate for the signal coming from $A^0 \to ZZ$. Our conclusions are left for section V.

II. THE TWO HIGGS DOUBLET MODEL (2HDM)

In order to specify the 2HDM versions, of types I, II and III, one needs to define the Yukawa sector, which includes the interactions of the Higgs doublets with the quarks and leptons. Interactions with gauge bosons come from the covariant derivatives, and the pattern of spontaneous symmetry breaking is associated with the Higgs potential. The general 2HDM-III is defined by the Yukawa lagrangian:

$$\mathcal{L} = Y_u^a d_L^a \Phi_1 u_R^a + Y_d^a Q_L^a \Phi_2 d_R^a + Y_1^u d_L^a \Phi_3 u_R^a + Y_2^d Q_L^a \Phi_4 d_R^a + h.c.$$  \hspace{1cm} (1)

where

$$Q_L^a = \begin{pmatrix} u_L^a \\ d_L^a \end{pmatrix}, \quad Q_R^a = \begin{pmatrix} u_R^a \\ d_R^a \end{pmatrix}, \quad \Phi_1 = \begin{pmatrix} \phi_1^+ \\ \phi_1 \end{pmatrix}, \quad \Phi_2 = \begin{pmatrix} \phi_2^+ \\ \phi_2 \end{pmatrix}, \quad \Phi_3 = \begin{pmatrix} \phi_3^+ \\ \phi_3 \end{pmatrix}, \quad \Phi_4 = \begin{pmatrix} \phi_4^+ \\ \phi_4 \end{pmatrix},$$  \hspace{1cm} (2)

and $\phi_i = \frac{1}{\sqrt{2}}(v_i + \phi_i^0 + i\chi_i)$.

For the purposes of this paper, it suffices to consider the case when the Higgs sector is CP conserving, then the CP-even Higgs states ($h$ and $H$) come from the mixing of the real parts of the neutral components, $\phi_1^0$ and $\phi_2^0$, while one combination of the imaginary components, $\chi_1^0$ and $\chi_2^0$, give place to the pseudo-Goldstone boson (needed to give mass to the $Z$ boson), while the corresponding orthogonal combination denotes the CP-odd state $A^0$. The mixing angles $\alpha$ and $\beta$ that appear in the neutral Higgs mixing, corresponds to the standard notation, i.e. $\tan \beta = v_2/v_1$.

Then, the interactions of the pseudoscalar Higgs boson ($A^0$) with the up-type quarks, are given by the following lagrangian:

$$\mathcal{L}^{neutral}_u = \bar{u}_i \left( S_{ij}^u + i\gamma^5 P_{ij}^u \right) u_j A^0 + h.c.$$  \hspace{1cm} (3)

with :

$$S_{ij}^u = \frac{\sqrt{m_i m_j}}{2\sqrt{2} v \cos \beta} \left( \chi_{ij} - \chi_{ij}^\dagger \right),$$  \hspace{1cm} (4)

$$P_{ij}^u = \frac{1}{2v} M^u_{ij} \tan \beta - \frac{\sqrt{m_i m_j}}{2\sqrt{2} v \cos \beta} \left( \chi_{ij} + \chi_{ij}^\dagger \right).$$  \hspace{1cm} (5)

Similar equations hold for d-type quarks and leptons, see [24].

As it is discussed in ref [23], the assumption of universal textures for the Yukawa matrices, allows to express one Yukawa matrix in terms of the quark masses, and parametrize the Flavor Changing Neutral Scalar Interactions (FCNSI) in terms of the unknown coefficients $\chi_{ij}$, which appear in the other Yukawa matrix, namely $Y_{2ij}^u = \chi_{ij} \frac{m_j}{m_i}$, although other combinations are possible, for instance the complementary textures discussed in ref. [25]. These parameters can be constrained by considering all types of low energy FCNC transitions; and although these constraints
are quite strong for transitions involving the first and second families, as well as for the b-quark, it turns out that they are rather mild for the top quark \[26, 27\].

Furthermore, we only need to look at the diagonal couplings of \(A^0\) to up-, down-type quarks and charged leptons, denoted generically as \(f_i\), because of their contribution to the loop amplitudes. Thus, the relevant Lagrangian can be written as:

\[
\mathcal{L}_{A^0}^f = \frac{g m_f^2}{2 m_W} f_i \left( g^f_{S_i} + i \gamma^5 g^f_{P_i} \right) f_i A^0. \tag{6}
\]

When the Yukawa matrices are taken to be hermitian, only the pseudoscalar coupling remains, i.e. \(g^f_{S_i} = 0\), and one finds for the diagonal coupling:

\[
g^f_{P_i} = \cot \beta - \frac{1}{\sin \beta} (\chi_{ii}), \tag{7}
\]

where the \(\chi_{ii}\) can be taken essentially as free parameters.

For 2HDM I and II, the \(\chi\) vanish, and thus only the pseudoscalar part contribute. Table I shows the vertex \(A^0 f \bar{f}\) for \(f = u, d\) type-quarks, within the CP-conserving case.

| Type |\(g^h_i\)|\(g^p_i\)|\(g^l_i\)|
|------|-------|-------|-------|
| Type I | \(\cot \beta\) | \(-\cot \beta\) | \(-\cot \beta\) |
| Type II | \(\cot \beta\) | \(\tan \beta\) | \(\tan \beta\) |
| Type III | \(\cot \beta - \frac{1}{\sin \beta} (\chi^u_{ii})\) | \(\tan \beta - \frac{1}{\cos \beta} (\chi^a_{ii})\) | \(\tan \beta - \frac{1}{\cos \beta} (\chi^l_{ii})\) |

### III. THE GENERAL EXPRESSIONS FOR THE AMPLITUDES AND DECAY WIDTHS FOR \(A \rightarrow V V'\)

In this section we shall present the calculation of the one-loop amplitude for the decay \(A \rightarrow V V'\), where \(V, V'\) represent any neutral SM vector boson \((V, V' = \{\gamma, Z\})\). Due to the parity properties of the pseudoscalar \(A^0\), the vertex \(AV V'\) is not present at tree level when the Higgs sector is CP-conserving. However, at one loop level this vertex could be induced; here we shall focus on the fermionic contributions. The Feynman diagrams for the amplitude are shown in figure 1. We shall consider the most general \(A^0 f \bar{f}\) couplings, i.e. allowing for the possibility of having a new source of CP violating associated with the non-hermiticity of the Yukawa matrices \(^1\). Then we shall present specific formulae for the decay widths within the 2HDM I, II and general III-type.

#### A. The decay amplitudes for \(A \rightarrow V V'\)

Thus, the amplitude for the process \(A \rightarrow V V'\), will be written in general, namely we shall consider in equation (6) The fermion-gauge vertices are written as: \(g_{V f f} = -ik_{V f f} \gamma_\mu (g^v_\mu - g^a_\mu \gamma^5)\), then for \(V = Z\) we have \(k_{Z f f} = \frac{i}{4 \cos \beta}\), and for \(V = \gamma, k_{\gamma f f} = e|Q_f|, g^v_\mu = 1, g^a_\mu = 0\).

\(^1\) The numerical analysis for the case with CPV in the Higgs potential, and its comparison with CPV from the Yukawa sector will be presented in a future publication.
FIG. 1: Feynman diagram for $A \to VV'$ decay, only fermion particles are present. Crossed diagram is not shown.

The kinematics conditions are defined according to the following configuration of momentum: $p_3 = p_1 + p_2$. Then according to figure 1 we have that: $p_3^2 = m_A^2$, $p_1^2 = m_V^2$, $p_2^2 = m_V^2$, and $2p_1 \cdot p_2 = m_A^2 - m_V^2 - m_V^2$.

The general tensorial amplitude for $AVV'$ vertex is written as follows,

$$\mathcal{M}_{\mu_1\mu_2} = \frac{ig r_f N_C k_{V_1f} k_{V_2f}^*}{16m_W^2(1 - 2(r_1 + r_2) + (r_1 - r_2)^2)\epsilon_{\mu_2}^* \epsilon_{\mu_2}^*},$$

(8)

where $r_i = \frac{M^2_{V_i}}{m_A^2}$, and:

$$A_{\mu_1\mu_2}^{V_{V'}} = g_S^f (A_1 g_{\mu_1\mu_2}^{fV} + A_2 p_{1\mu_1}^{fV} p_{2\mu_2}^{fV}) + g_p^f A_3 \epsilon_{\alpha\mu_1\mu_2}^{fV} p_{1\alpha} p_{2\alpha},$$

(9)

here one can see how the $A^0 f\bar{f}$ couplings give place to different tensorial structures, with the pseudoscalar part (i.e. $g_{\mu_1}^f$) inducing the term proportional to the Levi-Civita tensor, as expected. The corresponding form factors are given by:

$$A_1 = g_{fV_1} g_{fV_2} m_A^2 (r_1^2 - 2(r_2 + 1)r_1 + (r_2 - 1)^2) \times$$

$$\left(\left\{\frac{m_A^2}{2}(4r_f + 2r_1(r_f - r_2 - 3) - 4(r_2 + 2)r_f + r_1^2 + r_2^2 + 1) - 1\right\} + \left\{1 \leftrightarrow 2\right\}\right)$$

$$+ 2r_1(1 - r_1 + r_2)\Delta B_0(A, V_1) + 2r_1^2 - 2(r_2 + 2)r_1 + 1\right\} + \left\{1 \leftrightarrow 2\right\}\right)$$

$$+ g_{fV_1} g_{fV_2} m_A^2 (r_1^2 - 2(r_2 + 1)r_1 + (r_2 - 1)^2) \times$$

$$\left(\left\{\frac{m_A^2}{2}(2r_1^2(-4r_f - r_2 - 1) + 2r_1(8r_f + r_2(4r_f - 1) - 1) - 4r_f + 2r_1^3 + 1)\right\} + \right\{1 \leftrightarrow 2\right\}\right)$$

$$+ 2(2r_2r_1 - r_1^2 - r_2^2 + 2r_1 + 2r_2 - 1)B_0^R + 2(r_2^2 - r_1r_2 - 2r_2 - r_1 + 1)\Delta B_0(A, V_1)$$

$$+ 2r_1^2 - 2(r_2 + 2)r_1 + 1\right\} + \left\{1 \leftrightarrow 2\right\},$$
\[ A_2 = g^f_{a_1} g^f_{a_2} \left( m_A^2 (r_1 + r_2 - 1) C_0(V_1, V_2) \times \right. \]
\[
\left. \left( 2 r_1^2 \left( 4 r_f - r_2 - 3 \right) - 2 r_1 \left( 8 r_f + r_2 (4 r_f - 5) - 3 \right) + 4 r_f + 2 r_1^3 - 1 \right) + 4 \left( r_1^2 + 4 r_f r_1 - 2 r_1^2 - 5 r_f^2 r_1 + 4 r_f r_1 - (r_1 - (r_2 + 2) r_1 + 2 r_2 + 1) r_1 + r_1 \right) B_0^R(A) \right. \]
\[
\left. + 4 (r_1^2 - 4 r_f r_1^2 + 2 r_1^2 - 5 r_f^2 r_1 - 4 r_f r_1 - r_1) \Delta B_0(A, V_1) \right) + 4 r_1 \left( r_1^2 - (r_2 + 3) r_1 - r_2 + 3 \right) - 2 \right) + \left\{ 1 \leftrightarrow 2 \right\} \right) \]
\[
+ (r_1 + r_2 - 1) g^f_{a_1} g^f_{a_2} \times \left( m_A^2 \left( 4 r_f + r_1 (4 r_f - r_2 - 1) - 4 (r_2 + 2) r_f + r_1^2 + 3 r_2 - 1 \right) + 1 \right) C_0(V_1, V_2) \]
\[
+ 4 \left( r_1^2 - 2 r_1 - r_2^2 + 2 r_2 \right) B_0^R + 4 (r_2 - 1)^2 + (r_2 + 1) r_1 - 2 r_1^2) \Delta B_0(A, V_1) \right) + 4 r_1^2 - 4 (r_2 + 2) r_1 + 2 \right) \right) + \left\{ 1 \leftrightarrow 2 \right\} \right), \]

and
\[
A_3 = -m_A^2 g^f_{a_1} g^f_{a_2} \left( \left\{ 2 r_1^2 - 8 (r_1 + r_2 - 1) r_1^2 + 2 \left( 3 r_1^2 + 4 r_f + 6 \right) r_1^2 + 4 (r_2 - 2) r_1 + 1 \right\} + \left\{ 1 \leftrightarrow 2 \right\} \right) C_0(V_1, V_2) \]
\[
- g^f_{a_1} g^f_{a_2} \left( r_1^2 - 2 (r_1 + 1) r_1 + (r_2 - 1)^2 \right) \times \left( \left\{ m_A^2 (2 r_1^2 - 2 r_2 r_1 - 1) C_0(V_1, V_2) - 4 (r_1 - r_2 + 1) \Delta B_0(A, V_1) \right\} + \left\{ 1 \leftrightarrow 2 \right\} \right). \]

Where \( B_0(i) = B_0(m_i^2, m_j^2, m_f^2), \Delta B_0(i, j) = B_0(i) - B_0(j), \ C_0(i, j) = C(m_A^2, m_i^2, m_j^2, m_f^2). \) We have used the renormalization method described in [28], which allows us to write: \( B_0^R = B_0(m_A^2, m_i^2, m_j^2, m_f^2) - B_0(0, \mu_R^2, \mu_R^2), \) where \( \mu_R \) denotes a renormalization scale. These expressions show the Bose symmetry explicitly.

**B. The decay widths for \( A^0 \to ZZ, Z\gamma, \gamma\gamma \)**

In this section we shall present the expressions for the decay widths corresponding to the processes: \( A^0 \to ZZ, Z\gamma, \gamma\gamma, \) which follow from the above expressions for the amplitudes.

1. The expression for the decay width for \( A^0 \to ZZ \) is,
\[
\Gamma(A^0 \to ZZ) = m_A \kappa_{ZZ} r_f^2 \left( \frac{g_s^2}{1 - 4 r_Z^2} \right)^{1/2} \left( g_a^4 g_a^{ZZ} + 2 g_a^4 g_a^{ZZ} + 4 g_v^4 g_v^{ZZ} \right) + \frac{g_p^2}{2} \left( g_a^2 F^{ZZ} - g_v^2 F^{ZZ} \right)^2, \]
\[
(10) \]

where \( \kappa_{ZZ} = \frac{(N_f)^2}{64 \pi^2} \left( \frac{g_{m_A}}{2 M_W} \right)^2 \left( -\frac{g}{4 \cos \theta_W} \right)^4. \) The \( G \)’s and \( F \)’s functions contain Passarino-Veltman functions and also depend on the ratios \( r_f \) and \( r_Z. \)

2. The decay width for \( A^0 \to Z\gamma \) is given by the following expression:
\[ \Gamma(A^0 \to Z\gamma) = m_A g_f^2 \kappa_{Z\gamma} \left( g_f^2 m_A^4 (r_Z - 1)^4 C_0(m_Z, 0)^2 + 2 g_s^2 \left( m_A^2 (1 - r_Z)(4 r_f + r_Z - 1) C_0(m_Z, 0) + 2 (\Delta B_0(m_A, m_Z, 0) - 1) r_Z + 2 \right)^2 \right) \],

where \( \kappa_{Z\gamma} = \left( \frac{N_f}{64 \pi^2} \right)^2 \left( \frac{g_m f}{2 m_W} \right)^2 (2 g_s^2) \left( e |Q_f| \right)^2. \]

3. The decay width for \( A^0 \to \gamma\gamma \) is given by:

\[ \Gamma(A^0 \to \gamma\gamma) = m_A r_f \kappa_{\gamma\gamma} \left( I_f g_f^2 + 2 g_s^2 I_f (4 r_f - 1) + 2 \right)^2, \]

where \( I_f = C_0(0, 0) m_A^2 \) and \( \kappa_{\gamma\gamma} = \left( \frac{N_f}{128 \pi^2} \right)^2 \left( \frac{g_m f}{2 m_W} \right)^2 \left( e |Q_f| \right)^2. \)

IV. RESULTS AND LHC ANALYSIS

The recent LHC results have shown that the observed higgs boson properties are very similar to the ones predicted by the SM, although some small deviations have persisted, which would suggest the possible presence of new physics effects. Within the 2HDM, those new effects depend on the mixing angles and the scale \( \mu_{12} \), and thus in order to get small deviations with respect to SM, we shall choose the following set of parameters:

\[ \mu_{12} = 200 \text{ GeV} \sim v, \]
\[ \beta - \alpha = \frac{\pi}{2} + \delta, \]

where \( v \) is the electroweak scale, and \( \delta \) is small. Thus, the above scenario remains close to the SM limit.

A. Numerical results for the branching ratios

For the 2HDM of type II, the mass of the charged Higgs is constrained to be above a value of order 350 GeV. For the 2HDM of type-I the charged Higgs mass is less constrained, and it is possible to have a light charged Higgs, and similarly for the 2HDM of type III [29]. However, in order to explore a common scenario for 2HDM of type I, II and III, we shall consider \( m_{H^\pm} = 350 \text{ GeV} \).

In figure 2 we show the results for the branching ratio of the pseudoscalar boson \( A^0 \) for the 2HDM of type I and II. For THDM-I (see left plot a in figure 2), we can see that whenever the channels \( Zh, ZH, WH^\pm \) are kinematically allowed, they become dominant, and the rest of the modes are suppressed, except for the decay into top quark pair which can dominate in a small window around 350-400 GeV. The mode \( A^0 \to \gamma\gamma \) has a BR of order \( 10^{-4} \) in the best case, for \( m_A \approx 200 \text{ GeV} \), while the BR for the modes \( \gamma Z \) and \( ZZ \) is suppressed with respect to \( \gamma\gamma \) by one and two orders of magnitude, respectively. However, when the mass of \( A \) is not enough to produce the final states \( Zh, ZH, WH^\pm \), the modes \( b\bar{b}, gg \) or even \( \tau\tau \) could become relevant.

For 2HDM-II (see right plot b in figure 2), the modes \( b\bar{b} \) and \( ZH \) are the dominant channels, while the decay into gluons gets more suppressed. In this case the mode \( A^0 \to \gamma\gamma \) has a BR of order \( 2 \times 10^{-5} \), at most, for \( m_A \approx 350 \text{ GeV} \), while the BR for the modes \( \gamma Z \) and \( ZZ \) is about one order of magnitude smaller.
FIG. 2: Branching ratios for the pseudoscalar $A^0$ in 2HDM of type I and II. The parameter are: $m_H = 300$ GeV, $m_h = 125$ GeV, $m_{H^\pm} = 350$ GeV, $\tan \beta = 5$ and $\delta = 0.1$.

In figure 3 we present the results for the BR corresponding to the 2HDM of type III, in the $CP$-Conserving limit. But even in this case the Yukawa couplings are different with respect to the models with $Z_2$-symmetry, as it was shown in table I. In plot a we considered $\chi_{ff} = -1$, and for a light boson $A^0$ the most important channel is $A^0 \rightarrow b\bar{b}$. In this case we find $B.R.(A^0 \rightarrow \gamma\gamma) \simeq 2 \times 10^{-4}$ for $m_{A^0} \simeq 350$ GeV. For the same mass, the modes $A^0 \rightarrow \gamma Z, ZZ$ have BR’s of order $10^{-5}$. On the another hand, in plot b we fix $\chi_{ff} = 1$, and this choice significantly affects the channels $A^0 \rightarrow b\bar{b}$ and $A^0 \rightarrow \tau\tau$, reducing them even by about one order of magnitude. For this reason, the $B.R.(A^0 \rightarrow gg)$ becomes the dominant one for low masses. But now the mode $\gamma\gamma$ gets enhanced, and can reach B.R. of order $6 \times 10^{-3}$. The modes $\gamma Z$ and $ZZ$ are also enhanced, but have BR at most of order $3 \times 10^{-4}$.

In figure 4 we show the dependence of the BR’s as a function of $\tan \beta$. From these plots it is possible to see that the 2HDM-II present the most sensitive results, showing a variation of four orders of magnitude for $\gamma\gamma$ and $\gamma Z$, and more than four orders of magnitude for $ZZ$. In contrast, the 2HDM-III with $\chi_{ff} = 1$ is less sensitive to $\tan \beta$; this scenario presents small variations (of order unity) for all cases.

FIG. 3: Branching ratios for the pseudoscalar $A^0$ within 2HDM of type III in the $CP$-conserving limit. The parameter are choosen as: $m_H = 300$ GeV, $m_h = 125$ GeV, $m_{H^\pm} = 350$ GeV, $\tan \beta = 5$ and $\delta = 0.1$. 
FIG. 4: Behavior of $B_r(A^0 \rightarrow VV')$ as a function of $\tan \beta$. The parameter are chosen as: $m_H = 300$ GeV, $m_h = 125$ GeV, $m_{H^\pm} = 350$ GeV and $\delta = 0.1$. The assignment of color codes appears in the plot a.

B. Constraints from LHC search for heavy Higgs bosons

The first constraint that any extended model should fulfill nowadays is the occurrence of a light Higgs state with a mass near $m_{h^0} \approx 125$ GeV. After considering the results, including statistical and systematic uncertainties reported by ATLAS and CMS [1, 2], we consider a central value for $m_{h^0}$ of 125 GeV and an uncertainty of $\pm 3$ GeV, i.e. we accept a value of $m_{h^0}$ in our numerical analysis if it lies within the range [122 GeV, 128 GeV]. Next, we also need to fulfill the constraints coming from the comparison with the SM-like Higgs signal observed at the LHC. Thus, in order to compare the signal rate observed for the SM-like Higgs signals, with mass $m_{h^0} \approx 125$ GeV, arising within the 2HDM model, one can describe the signal strength by the following ratios:

$$R_{XX} = \frac{\sigma(gg \rightarrow h^0) \frac{BR(h^0 \rightarrow XX)}{\sigma(gg \rightarrow \phi_{sm}) \frac{BR(\phi_{sm} \rightarrow XX)}}}{\Gamma(h^0 \rightarrow gg) \frac{BR(h^0 \rightarrow XX)}{\Gamma(\phi_{sm} \rightarrow gg) \frac{BR(\phi_{sm} \rightarrow XX)}}}$$

(15)

for $X = \gamma, Z$.

Within the so called Narrow-width approximation, we can write the above expression for $R_{XX}$ as follows:

$$R_{XX} = \frac{\Gamma(h^0 \rightarrow gg) \frac{BR(h^0 \rightarrow XX)}{\Gamma(\phi_{sm} \rightarrow gg) \frac{BR(\phi_{sm} \rightarrow XX)}}}{\Gamma(h^0 \rightarrow gg) \frac{BR(h^0 \rightarrow XX)}{\Gamma(\phi_{sm} \rightarrow gg) \frac{BR(\phi_{sm} \rightarrow XX)}}}$$

(16)

According to the CMS collaboration the signal strength for the $\gamma \gamma$ channel is $R_{\gamma \gamma} = 0.78^{+0.28}_{-0.26}$, while for the $ZZ$ channel is $R_{ZZ} = 0.9^{+0.30}_{-0.24}$. Thus, the light Higgs boson of the 2HDM, should satisfy the above conditions, which is achieved in our scenarios because the properties of the light Higgs boson were chosen to be very similar to the SM.

On the other hand, the LHC has also presented limits on the mass of a heavier Higgs boson, which could be used in order to obtain some constrains on the mass of the pseudoscalar state $A$. We are aware that the pseudoscalar nature
of $A$ will affect the distributions of the particles appearing in the final states, and strictly speaking those bounds that searched for the SM-Higgs cannot not be applied to the pseudoscalar. However, we shall assume that those differences are small enough, at least in order to obtain an estimate for the constraints on the corresponding mass.

For this purpose, we evaluate the ratio:

$$R_{XX} = \frac{\sigma(gg \rightarrow A^0) Br(A^0 \rightarrow XX)}{\sigma(gg \rightarrow \phi_{sm}) Br(\phi_{sm} \rightarrow XX)}$$

(17)

$$= \frac{\Gamma(gg \rightarrow A^0) Br(A^0 \rightarrow XX)}{\Gamma(\phi_{sm} \rightarrow gg) Br(\phi_{sm} \rightarrow XX)}$$

(18)

at a mass value $m_{\phi_{sm}} = m_A$, which we vary over the range $180 < m_A < 360$ GeV, in order to stay below the threshold for the decay into top pair, which becomes dominant then. The results are shown in the following figure 5, which shows the values of $R_{ZZ}$ and $R_{\gamma\gamma}$ vs. $m_A$ for 2HDM-I, II and III. We have included the CMS exclusion contour for each channel (ZZ and $\gamma\gamma$), and whenever the predictions from the models fall above these lines, such scenarios would be excluded.

From the left figure, we can see that all models satisfy the constraints imposed by the heavy Higgs search in the ZZ channel. On the other hand, we can see from the right figure, that the values of $R_{\gamma\gamma}$ bounded at LHC, could exclude the 2HDM of type III for the choice $\chi = 1$ in the whole mass range studied at LHC, namely $100 < m_A < 160$ GeV. The 2HDM of type II satisfy this constraint for the whole mass range, while 2HDM-I and 2HDM-III (with $\chi = 1$) seem to be excluded only in the mass range $138 < m_A < 144$ GeV. These are promising results which deserve to be looked at in more detail by the experimental collaborations.

**V. CONCLUSIONS**

As it is well known, the general two-higgs doublet model (2HDM) contains a rich spectrum of neutral and charged Higgs bosons, whose detection at current and future colliders would be a clear signal of new physics. When the Higgs potential is CP-conserving, the neutral spectrum includes a pseudoscalar mass eigenstate $A^0$. Even in this case, the interactions of $A^0$ with fermions could include a CP-violating contribution, arising from a possible non-hermicity of the Yukawa matrices. When the Higgs sector is CP-conserving, the $A^0$ boson does not couple to vector bosons at tree-level. However the coupling $(AVV')$ is generated at loop level, from fermionic and bosonic loops. The dominant contribution in the low and moderate $\tan \beta$ ($\simeq 1 - 5$), comes from the top quark, while for larger values of $\tan \beta$, the bottom quark contribution becomes relevant.

We have evaluated the generic fermionic contribution to the decays $A^0 \rightarrow ZZ, Z\gamma, \gamma\gamma$, including its scalar and pseudoscalar vertices. Then, we have present numerical results for the branching ratios. We have found that there are regions of parameters where such loop-induced modes could reach significant branching ratios. Current LHC searches for heavy Higgs bosons are used as an estimate to constrain the parameters of the models. We find that for 2HDM-II the whole mass range is acceptable, for our choices of parameters, while the 2HDM-III with $\chi = 1$ is excluded in the whole mass range ($100 < m_A < 160$ GeV). On the other hand, 2HDM-I and 2HDM-III (with $\chi = 1$) seem to be excluded only in the mass range $138 < m_A < 144$ GeV. These scenarios should be further studied at the LHC13 in order to confirm the exclusion estimates presented in this paper.
