Abstract
Relative expression levels of immune- and non-immune-related mRNAs in chicken intestinal intraepithelial lymphocytes experimentally infected with Eimeria acervulina, E. maxima, or E. tenella were measured using a 10K cDNA microarray. Based on a cutoff of >2.0-fold differential expression compared with uninfected controls, relatively equal numbers of transcripts were altered by the three Eimeria infections at 1, 2, and 3 days post-primary infection. By contrast, E. tenella elicited the greatest number of altered transcripts at 4, 5, and 6 days post-primary infection, and at all time points following secondary infection. When analyzed on the basis of up- or down-regulated transcript levels over the entire 6 day infection periods, approximately equal numbers of up-regulated transcripts were detected following E. tenella primary (1,469) and secondary (1,459) infections, with a greater number of down-regulated mRNAs following secondary (1,063) vs. primary (890) infection. On the contrary, relatively few mRNAs were modulated following primary infection with E. acervulina (35 up, 160 down) or E. maxima (65 up, 148 down) compared with secondary infection (E. acervulina, 1,142 up, 1,289 down; E. maxima, 368 up, 1,349 down). With all three coccidia, biological pathway analysis identified the altered transcripts as belonging to the categories of “Disease and Disorder” and “Physiological System Development and Function”. Sixteen intracellular signaling pathways were identified from the differentially expressed transcripts following Eimeria infection, with the greatest significance observed following E. acervulina infection. Taken together, this new information will expand our understanding of host-pathogen interactions in avian coccidiosis and contribute to the development of novel disease control strategies.

Introduction
Avian coccidiosis is caused by seven species of Eimeria protozoa (E. acervulina, E. maxima, E. tenella, E. mitis, E. necatrix, E. praecox, and E. brunetti) that differ in pathogenicity and immunogenicity [1,2]. The life cycles of all Eimeria species are of the monoxenous sporozoan type. Generally, infection develops following ingestion of sporulated oocysts and release of sporozoites, which subsequently invade intestinal epithelial cells. Through asexual reproduction, gametes are formed and fertilized to produce a zygote, which matures into an oocyst, ruptures the host cell, and is excreted in the feces. The entire cycle normally develops over the course of 4–6 days, depending on the species [3].

Eimeria infection inflicts significant economic losses to the commercial poultry industry due to decreased nutrient absorption, retarded growth rate, reduced egg production, and mortality [4,5]. Although prophylactic chemotherapy has been traditionally used for disease control, the emergence of drug-resistant parasites and legislative bans on the use of in-feed antibiotic growth promoters and non-therapeutic antimicrobial feed additives encourages the development of alternative coccidiosis control strategies [5]. Accordingly, there has been great interest in understanding the host-pathogen interactions at the cellular and molecular levels and to identify effector molecules mediating protective immunity to Eimeria.

Functional genomics and bioinformatics technologies have recently emerged as powerful technologies for investigation of host-pathogen interactions during avian coccidiosis [6,7,9,10,11]. New candidate genes which influence host immune responses to Eimeria have been identified using chicken macrophage and lymphocyte cDNA microarrays [6,7,10,11,12,13,14]. Host genetic alterations following Eimeria infection have been investigated employing a variety of new microarray data mining tools [15,16,17,18,19]. However, a comparative analysis of gene expression in gut lymphocytes in response to infection by different species of Eimeria has not been reported, which would aid in the...
understanding of species-related differences in parasite pathogenicity and immunogenicity. Therefore, this study was conducted to compare the global gene transcripts of the three species of coccidia that most commonly infect commercial poultry, *E. acervulina*, *E. maxima*, and *E. tenella*.

**Materials and Methods**

**Experimental animals and *Eimeria* infection**

All experiments were approved by the Beltsville Agriculture Research Center Small Animal Care and Use Committee (Protocol #09-019). One week-old chickens were uninfected (negative control) or were orally inoculated with sporulated oocysts of *E. acervulina*, *E. maxima*, or *E. tenella* (1.0×10^6 oocysts/bird). One week later, the infected chickens were challenged with an identical inoculum of the homologous parasite. Intestinal samples were collected daily from 5 birds in a treatment group at from 1 to 6 days post-infection (DPI) following primary and secondary infections. Cecum, duodenum, and jejunum were collected from the birds challenged with *E. acervulina*, *E. maxima*, and *E. tenella*, respectively.

**RNA extraction and aminoallyl-labeled RNA preparation**

Intestines were cut longitudinally and washed three times with ice-cold Hank’s balanced salt solution (HBSS) containing 100 U/ml of penicillin and 100 mg/ml of streptomycin (Sigma, St. Louis, MO). The mucosal layer of intestine was carefully scraped using a cell scraper and intraepithelial lymphocytes (IELs) were isolated by Percoll density gradient centrifugation as described (Min et al., 2005). Total RNA was isolated using Trizol (Invitrogen, Carlsbad, CA), and RNAs from animals in the same treatment group were pooled and purified using the RNeasy Mini RNA Purification Kit (Qiagen, Valencia, CA). Aminoallyl-labeled RNA was prepared using the Amino Allyl Message Amp II aRNA Amplification Kit (Ambion, Austin, TX) according to the manufacturer’s instruction. Two of 20 μg aliquots of each aminoallyl-RNA sample were fluorescently labeled with AlexaFluor 555 or AlexaFluor 647 (Invitrogen). RNA concentrations and labeling efficiencies were determined spectrophotometrically.

**Microarray hybridization**

The avian IEL array (AVIELA) consists of 10,162 spots representing duplicates of cDNAs from chicken IELs, immune-related cDNAs from lipopolysaccharide-activated HD11 chicken macrophages, and direct PCR clones of selected chicken cytokine and chemokine genes [8,11,12]. Uninfected control samples and one of the 3 infection group samples were labeled with different fluorescent dyes and hybridized simultaneously on the same slide using a reference design with a dye swap protocol [20]. Hybridizations were performed overnight at 50°C using HybIt hybridization buffer (Tel-Enzym, Sunnyvale, CA) in Arrayly reaction cassettes as described [11]. Following hybridization, the slides were rinsed in 0.5×SSC, 0.01% SDS and washed once for 15 min at room temperature in 0.2×SSC, 0.2% SDS at 50°C, 3 times for 1 min at room temperature in 0.2×SSC, and 3 times for 1 min at room temperature in distilled water.

**Quantitative RT-PCR**

Gene expression changes observed by microarray analysis were confirmed by quantitative qRT-PCR as described [7]. Equivalent amounts of the same RNA samples used for microarray hybridizations from 1–6 days post-primary or post-secondary infections with the different *Eimeria* species were pooled. The RNAs were reverse transcribed using the StrataScript First Strand Synthesis System (Stratagene, La Jolla, CA). Amplification and detection were carried out using the Mx3000P system and Brilliant SYBR Green qRT-PCR master mix (SABioscience, Frederick, MD). Oligonucleotide primers are listed in Table 1. Standard curves were generated using log_10 diluted standard RNA and the levels of individual transcripts were normalized to those of GAPDH by the Q-gene program [21]. The fold changes were calculated in the normalized mRNA levels between the uninfected control group and each infection groups. Each analysis was performed in triplicate and the comparisons of the mean values were performed by one-way analysis of variance (ANOVA) followed by the Duncan’s multiple range test using SPSS software (SPSS 15.0 for Windows, Chicago, IL).

**Bioinformatics analysis**

IEL cDNA sequences in the AVIELA were mapped to the chicken genome reference assembly (version 2.1) and to reference RNA and protein sequences using National Center for Bioinformatics Institute (NCBI) Blast (version 2.2.13). The networks and pathway information of genes which were differentially expressed were analyzed by Ingenuity Pathways Analysis (IPA) software (Ingenuity Systems, http://www.ingenuity.com). The dataset containing gene identifiers mapped to UniGene IDs in the chicken (*Gallus gallus*) database (Build #43) and corresponding expression values were uploaded into the application. Each identifier was mapped to its corresponding gene object in the Ingenuity knowledge base. Both up- and down-regulated identifiers were defined as value parameters for the analysis. These genes, called focus genes, were overlaid onto a global molecular network developed from information contained within IPA. Functional gene analysis was performed to identify the biological functions and canonical pathways of genes from the mapped datasets. The Fisher’s exact test was used to calculate P values to assess the probability that each biological function and pathway...
assigned to that dataset. Biological functions and pathways of those focus genes were generated based on their connectivity.

**Results**

Comparison of mRNA expression levels following infection with *E. acervulina*, *E. maxima*, or *E. tenella*

Using a cutoff of >2.0-fold differential expression compared with uninfected controls, relatively equal numbers of transcripts were altered at 1, 2, and 3 days post-primary infection with *E. acervulina*, *E. maxima*, or *E. tenella* (Figure 1). By contrast, *E. tenella* elicited the greatest number of altered transcripts at 4, 5, and 6 days post-primary infection, and at all time points following secondary infection. The numbers of transcripts that were significantly (P<0.0005) up- or down-regulated over the entire 6 day infection periods when comparing each infection group with uninfected controls are illustrated in Figure 2A. Approximately equal numbers of up-regulated transcripts were detected following *E. tenella* primary (1,469) and secondary (1,459) infections, with fewer down-regulated mRNAs following primary (890) vs. secondary (1,063) infection. On the other hand, only a small subset of mRNAs were modulated following primary infection with *E. acervulina* (35 up, 157 down) or *E. maxima* (65 up, 148 down) compared with secondary infection (*E. acervulina*, 1,142 up, 1,289 down; *E. maxima*, 368 up, 1,349 down). Figure 2B showed the number of the differentially expressed genes that were overlapped between the infections of three different *Eimeria* species. In the primary and secondary infections, the genes commonly changed by three species were three and three hundred sixty one, respectively. When comparing the total number of transcripts altered between 1–6 DPI following primary or secondary infection, the levels of 430 mRNAs were greater in primary vs. secondary infection with *E. acervulina*, and 389 transcript levels were greater in secondary vs. primary infection (Figure 3). For *E.

Table 1. Primers used for quantitative RT-PCR.

Figure 1. Comparison of the number of intestinal lymphocyte transcripts with <2.0-fold altered levels following primary (1<sup>st</sup>) and secondary (2<sup>nd</sup>) infections by *E. acervulina* (EA), *E. maxima* (EM), or *E. tenella* (ET) compared with uninfected controls (P<0.05).

doi:10.1371/journal.pone.0027712.g001
maxima, 472 transcripts were greater following primary and 449 transcripts were greater after secondary infection. Relatively equal numbers were altered following E. tenella infection (42 vs. 41). Next, we compared the numbers of transcripts between early (1–3 DPI) and late (4–6 DPI) primary or secondary infections whose levels were altered compared with uninfected controls (P < 0.01). As shown in Figure 4, following primary infection with E. acervulina, E. maxima, or E. tenella, more transcripts were altered between 1–3 DPI compared with 4–6 DPI. By contrast, there were essentially no differences between these two time frames after secondary infection with any of the coccidia parasites. All of the annotated genes that were differentially expressed by three species of Eimeria in primary or secondary infections and between early and late primary infections are shown in Table S1 and Table S2, respectively.

Quantitative RT-PCR confirmation

The expression patterns observed by microarray hybridization were validated by qRT-PCR with 6 transcripts whose levels were significantly modulated during primary or secondary infection compared with uninfected controls. These genes were adenosine deaminase (ADA), beclin 1, autophagy related (BECN1), chemokine (C-C motif) ligand 20 (CCL20), CD8α (CD8A), Toll-like receptor 4 (TLR4), and interleukin-6 (IL-6). The levels of all 6 transcripts that were up- or down-regulated by microarray analysis were also consistently up- or down-regulated when analyzed by qRT-PCR (Table 2). As previously discussed, the differences in the magnitude of the changes observed might be due to differences in the normalization methods used and/or the different fluorescent dyes used by the two protocols [22].

Biological pathway analysis of differentially regulated transcripts

Biological function analysis using the IPA database was performed for the mRNAs that were differentially altered (P < 0.0005) following Eimeria primary or secondary infections, compared with uninfected controls. In this manner, the transcripts were classified under the categories of “Disease and Disorder” or “Physiological Development and Function”. In the “Disease and Disorder” category, 10 unique biological functions were identified, all of which were recognized following primary infection with one or more of the coccidia parasites (Table 3). A subset of five of these (“Cancer”, “Genetic Disorder”, “Gastrointestinal Disease”, “Infectious Disease”, “Infection Mechanism”) were also identified following secondary infection with all of the denoted Eimeria species. In the category of “Physiological Development and Function”, 10 unique biological functions were identified, but only those related to “Cell-mediated Immune Response” and “Hematological System Development and Function” were universally identified following primary E. acervulina, E. maxima, or E. tenella infection (Table 4).

Network analysis of differentially regulated transcripts

Sixteen signal transduction pathways were identified from the differentially expressed transcripts following infection with all three Eimeria species, compared with uninfected controls (Figure 5). With the exception of the HMGB1 (high-mobility group protein B1) pathway, the greatest statistical significance was observed between these mRNAs and E. acervulina infection for all pathways. Seven of the pathways identified (“CD28 Signaling in T Helper Cells”, “fMLP Signaling in Neutrophils”, “HMGB1 Signaling”, “IL-3
Signaling”, “IL-4 Signaling”, “Production of Nitric Oxide and Reactive Oxygen Species in Macrophages”, “Role of NFAT in Regulation of the Immune Response”) are included in the category of “Cellular Immune Response”, and four pathways are located in the category of “Humoral Immune Response” (“B Cell Receptor Signaling”, “HMGB1 Signaling”, “IL-4 Signaling”, “Role of NFAT in Regulation of the Immune Response”).

Because the comparison of modulated transcripts revealed that the vast majority of alterations between 1–3 DPI and 4–6 DPI were seen following primary, but not secondary, infection (Figure 4), further network analysis was performed using these two time frames. Shown in Table 5 are the associated network functions, and the number of their corresponding focus genes, that were identified by comparison of the altered transcripts at 1–3 DPI with those at 4–6 DPI following primary infection with the three coccidia parasites. Focus genes are those identified and mapped to corresponding gene objects in the IPA database, and whose expression is significantly differentially regulated in a given network. The network functions with the greatest number of focus genes that were identified were “Genetic Disorder, Metabolic Disease, Amino Acid Metabolism” and “Lipid Metabolism, Small Molecule Biochemistry, Amino Acid Metabolism” for *E. acervulina* infection, “Lipid Metabolism, Molecular Transport, Small Molecule Biochemistry” for *E. maxima* infection, and “Carbohydrate Metabolism, Lipid Metabolism, Small Molecule Biochemistry” for *E. tenella* infection.

### Discussion

The monoxenous life cycle of *Eimeria* is complex and involves intracellular, extracellular, asexual, and sexual stages for invasion and reproduction. It is therefore not surprising that avian immune responses against the parasite are correspondingly complicated, involving aspects of innate vs. adaptive, humoral vs. cellular, and passive vs. active immunity [1,2]. Because the *Eimeria* life cycle is normally completed in 4–6 days, depending on the particular coccidia species, this study was designed to examine variations in gene expression during the first 6 days following primary or secondary infection. Our findings are summarized as follows: (a) whereas infection by all three *Eimeria* species altered the levels of relatively equal numbers of transcripts at 1–3 DPI following primary infection, *E. tenella* elicited the greatest number of altered transcripts at 4–6 DPI post-primary infection, and at all time levels following secondary infection.

doi:10.1371/journal.pone.0027712.g004
points following secondary infection, (b) while equivalent numbers of up-regulated transcripts were detected following E. tenella primary and secondary infections, relatively fewer mRNA were modulated following primary vs. secondary infection with E. acervulina or E. maxima, (c) irrespective of the coccidia used for infection, biological pathway analysis identified the altered transcripts as belonging to the categories of “Disease and Disorder” and “Physiological System Development and Function”, and (d) 16 intracellular signal transduction pathways were identified from the differentially expressed transcripts following Eimeria infection, several of which are directly relevant to protective immunity, including those for IL-3, IL-4, CD28, nitric oxide, nuclear factor of activated T cells (NFAT), and the B cell receptor.

These results confirm and extend our prior study which identified lymphocyte transcripts that were altered following E. acervulina infection of naïve chickens [6]. In addition to modulation of immune-related transcripts, these two reports also suggest that the expression of genes related to cellular metabolism, especially lipid metabolism, are altered during coccidia infection. Correspondingly, following primary Eimeria infection, it is the asexual replicative phase that is responsible for the majority of intestinal tissue damage, with negative consequences for nutrient absorption [23]. Therefore, it is not unexpected to detect changes in the expression of genes related to host metabolic function during the primary infection. In particular, several mRNAs encoding proteins with known effects on lipid metabolism were altered by Eimeria infection. These include perilipin 2 (PLIN2), which was increased subsequent to primary infection by E. acervulina and E. maxima, as well as prostaglandin reductase 1 (PTGR1), CD36, and carnitine O-octanoyltransferase (CROT), which were decreased following E. acervulina primary infection. Moreover, E. maxima infection suppressed the expression of the lipid-related mRNAs for scavenger receptor class B, member 1 (SCARB1), hydroxysteroid (11-β) dehydrogenase 1 (HSD11B1), hydroxysteroid (17-β) dehydrogenase 4 (HSD17B4), solute carrier organic anion transporter

1Datasets were analyzed by BioFunction analysis using IPA software. Functions are listed in descending order of statistical significance with the most significant at the top of each Eimeria species grouping.

2P values were calculated using the right-tailed Fisher’s exact test.

doi:10.1371/journal.pone.0027712.t003
family, member 2A1 (SLCO2A1), while *E. tenella* infection decreased that for glycerol-3-phosphate acyltransferase, mitochondrial (GPAM). Following both primary and secondary infections, *E. tenella* modulated the levels of the greatest number of transcripts compared with uninfected controls (primary, 2,359; secondary, 2,522), as opposed to *E. acervulina* (primary, 195; secondary, 2,431) and *E. maxima* (primary, 213; secondary, 1,717). *E. tenella* is known to cause cecal or "bloody" coccidiosis, and primarily invades the intestinal ceca [24]. Severe intestinal bleeding, eroding of the mucosal surface, and thickening of the cecal wall are all clinical signs of *E. tenella* infection. By 6–8 DPI, rupture of the cecal wall may occur, with associated high mortality [25]. Relevant to this topic, our biological function analysis identified *E. tenella*-elicited transcripts in the category "Hematological System Development and Function" and "Hematopoiesis" of "Physiological System Development and Function", with 126 and 80 focus genes, respectively. Among these genes related to hematological functions were adenosine deaminase (ADA), BCL2-related protein A1 (BCL2A1), caspase 1, apoptosis-related cysteine peptidase (CASP1), chemokine (C-C motif) receptor 9 (CCR9), chemokine (C-X-C motif) receptor 4 (CXC4), CD5, CD44, CD69, cyclin D1 (CCND1), IL-6, and IL-10 receptor α (IL10RA).

Whereas *E. tenella* altered the expression of the greatest number of transcripts, compared with uninfected chickens, comparisons between primary and secondary infections revealed the fewest number of modified transcripts for this species. In other words, primary infection with *E. tenella* induced the greatest transcriptional response in intestinal lymphocytes that was maintained during secondary infection. These results imply that primary infection of *E. tenella* may be more likely to induce protective immunity, compared with *E. acervulina* or *E. maxima*. Although the particular immune effector cell(s) involved in protective immunity against individual *Eimeria* species remain to be determined, previous studies showed that depletion of CD4+ lymphocytes enhanced primary infection by *E. tenella*, but did not influence the course of *E. acervulina* infection, suggesting that this subpopulation is important in controlling primary infection by the former but not the latter [26]. On the contrary, no differences between the two coccidia were noted following depletion of CD8+ cells. Ongoing studies in our laboratory are designed to characterize the transcriptional profiles of CD4+, CD8+ and other intestinal lymphocyte subpopulations following primary and secondary infection with the different coccidia species.

In summary, this report describes the transcriptional responses of chicken intestinal lymphocytes following in vivo experimental

### Table 4. Biological functions in the category “Physiological System Development and Function” of the transcripts differentially expressed by primary *Eimeria* infection.

| *Eimeria*     | Biofunction                              | P value          | No. of Genes |
|--------------|------------------------------------------|------------------|--------------|
| *E. acervulina* | Hepatic System Development and Function | 8.96E-04 - 4.48E-02 | 3            |
|              | Cell-mediated Immune Response            | 5.08E-03 - 4.96E-02 | 4            |
|              | Endocrine System Development and Function | 5.08E-03 - 4.96E-02 | 4            |
|              | Hematological System Development and Function | 5.08E-03 - 4.96E-02 | 7            |
|              | Hematopoiesis                            | 5.08E-03 - 4.96E-02 | 6            |
| *E. maxima*  | Tissue Morphology                        | 4.17E-04 - 4.63E-02 | 9            |
|              | Reproductive System Development and Function | 7.79E-04 - 4.18E-02 | 10           |
|              | Hematological System Development and Function | 9.87E-04 - 4.63E-02 | 13           |
|              | Renal and Urological System Development and Function | 1.67E-03 - 2.34E-02 | 6            |
|              | Cell-mediated Immune Response            | 1.70E-03 - 4.63E-02 | 8            |
| *E. tenella* | Hematological System Development and Function | 2.41E-05 - 6.85E-03 | 126          |
|              | Hematopoiesis                            | 2.41E-05 - 2.82E-03 | 80           |
|              | Cell-mediated Immune Response            | 4.80E-05 - 2.69E-03 | 59           |
|              | Connective Tissue Development and Function | 1.67E-04 - 6.85E-03 | 54           |
|              | Digestive System Development and Function | 2.11E-04 - 5.20E-03 | 18           |

1Datasets were analyzed by BioFunction analysis using IPA software. Functions are listed in descending order of statistical significance with the most significant at the top of each *Eimeria* species grouping.

2P values were calculated using the right-tailed Fisher’s exact test.

Figure 5. Network analysis of differentially regulated transcripts. The significantly modified signaling pathways (P<0.05) for the transcripts differentially expressed following primary and secondary infections by *E. acervulina* (EA), *E. maxima* (EM), or *E. tenella* (ET). A1; EA, A2; EM, and A3; ET. doi:10.1371/journal.pone.0027712.g005
infection with *E. acervulina*, *E. maxima*, or *E. tenella* using the AVIELA microarray. Biological function and pathway analysis identified the altered transcripts being relevant to lipid metabolism, as well as cellular and humoral immunity. These new developments further enhance our understanding of the host response to *Eimeria* infection that may someday contribute to the development of the alternative control strategies against avian coccidiosis whose treatment has traditionally relied upon prophylactic medication and antibiotics.

**Supporting Information**

Table S1 The annotated transcripts (P<0.0005) that were differentially expressed over the entire 6 day infection periods when comparing each infection group with uninfected controls.

| Species | No. of Focus Genes |
|---------|--------------------|
| *E. acervulina* | 26 |
| *E. maxima* | 22 |
| *E. tenella* | 27 |

Table S2 The annotated transcripts that were differentially expressed (P<0.01) between early (1–3 DPI) and late (4–6 DPI) primary infections with *E. acervulina*, *E. maxima*, or *E. tenella*.
