ABSTRACT

Introduction Despite renewed commitment to universal health coverage and health system strengthening (HSS) to improve access to primary care, there is insufficient evidence to guide their design and implementation. To address this, we conducted an impact evaluation of an ongoing HSS initiative in rural Madagascar, combining data from a longitudinal cohort and primary health centres.

Methods We carried out a district representative household survey at the start of the HSS intervention in 2014 in over 1500 households in Ifanadiana district, and conducted follow-up surveys at 2 and 4 years. At each time point, we estimated maternal, newborn and child health coverage; economic and geographical inequalities in coverage; and child mortality rates; both in the HSS intervention and control catchments. We used logistic regression models to evaluate changes associated with exposure to the HSS intervention. We also estimated changes in health centre per capita utilisation during 2013 to 2018.

Results Child mortality rates decreased faster in the HSS than in the control catchment. We observed significant improvements in care seeking for children under 5 years of age (OR 1.23; 95% CI 1.05 to 1.44) and individuals of all ages (OR 1.37, 95% CI 1.19 to 1.58), but no significant differences in maternal care coverage. Economic inequalities in most coverage indicators were reduced, while geographical inequalities worsened in nearly half of the indicators.

Conclusion The results demonstrate improvements in care seeking and economic inequalities linked to the early stages of a HSS intervention in rural Madagascar. Additional improvements in this context of persistent geographical inequalities will require a stronger focus on community health.

Key questions

What is already known?
- Low- and middle-income countries require substantial investments in health system strengthening (HSS) and universal health coverage (UHC) to reach the health-related Sustainable Development Goals.
- There is a major gap in the evidence to inform HSS and UHC policies due to challenges in the assessment of such complex interventions, with cross-benefits at the population level.

What are the new findings?
- After 4 years of integrating HSS activities across all levels of care within a government district, coverage increased by more than 4% per year for all recommended vaccines, for care seeking in children and adults, and for facility birth deliveries.
- We also observed overall improvements in maternal care coverage and child mortality rates in the HSS catchment, but differences with the control catchment were modest and not statistically significant.
- While economic inequalities in the coverage of most child and maternal health indicators were reduced, geographical inequalities worsened in nearly half of the indicators evaluated.

INTRODUCTION

As the world mobilises to develop vaccines and treatments for COVID-19, half of the global population lacks access to the essential health services necessary for preventing and treating the burden of illnesses that have been with us for far longer. To address this, most countries have renewed their commitment to universal health coverage (UHC) to achieve
What do the new findings imply?

- HSS interventions can have positive population-level effects by increasing care seeking and reducing economic inequalities, both central goals of UHC policies.
- Important gaps in geographical access to care can persist unless public health systems adequately strengthen community health programmes in remote, rural areas.
- Our study highlights the value of iterative learning between HSS implementation and impact evaluation, based on the dynamic integration of data and analytics at multiple levels of a health district.

Key questions

Our study highlights the value of iterative learning between HSS implementation and impact evaluation, based on the dynamic integration of data and analytics at multiple levels of a health district.

Methods

Study site and HSS intervention

Ifanadiana is a rural health district of approximately 180000 people located in the region of Vatovavy-Fitovinany, in southeastern Madagascar. Per Ministry of Public Health (MoPH) norms, Ifanadiana district has one reference hospital, one main primary care health centre (CSB2) for each of its 15 communes (subdivision of a district with ~15000 people; two additional CSB2s were built in 2016 and 2018), six additional basic health centres for larger communes (CSB1) and one community health site with two community health workers (CHW) for each of its 195 fokontany (subdivision of a commune with ~1000 population). The integrated health district is a key unit of analysis and implementation, but district-level evaluations are still scarce. 16 21–24 Even experimental trials that successfully demonstrate impact locally using robust evaluation methods generally fail to scale because the data and information loops necessary to continuously inform scale-up are not integrated with policy. 25–28 We accordingly lack evidence from data that are representative at the population level and sufficiently comprehensive to capture the cross-cutting benefits of HSS and UHC initiatives, while simultaneously being granular enough to inform policy and implementation. In this sense, adding adaptive evaluation designs that use robust data collection and analytics (eg, observational and quasi-experimental) in parallel to HSS interventions being implemented across the developing world can generate rigorous evidence while informing the implementation process via dynamic information loops and iterative learning.

Here, we take advantage of an HSS initiative in a rural district of Madagascar, a country with one of the least-funded health systems in the world. 29 Starting in 2014, the non-governmental organisation, PIVOT, partnered with the government of Madagascar to establish a model health system in the southeastern district of Ifanadiana. A range of HSS programmes were initiated in a third of the district, ensuring health system readiness, improving clinical programmes and supporting integrated information systems at all levels of care. The first 2 years showed improved quality and coverage of primary care services, 30 and declines in child mortality rates. 31 The scope of the programmes and geographical footprint are being progressively scaled, and the government of Madagascar has designated Ifanadiana among the districts for piloting the national UHC strategy. Combining surveys from a district-representative longitudinal cohort 32 with routine health system data, the goal of this study was to demonstrate how the dynamic integration of granular data and analytics at multiple levels of a health district can be used to evaluate the impact of local HSS initiatives, providing a platform for adaptive implementation. We assessed changes in health system coverage associated with the HSS intervention, with special attention to the evolution of economic and geographical inequity. Explicit information loops between research and implementation, via a web-based interface make cohort results accessible to programme managers for operational use throughout the scale-up phase.

Table 1  Summary of HSS interventions implemented in Ifanadiana district between 2014 and 2017, classified by building block of HSS* affected

| Level of care      | Ifanadiana district (idHSS+control catchments)                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------|
| District hospital  | 1. Network of three ambulances for referrals and emergency care; infrastructure renovations, provision of medical and non-medical equipment, including full laboratory capacity; social support for vulnerable patients  |
| Total Ifanadiana:  | 2. Staffing of health workers and non-clinical staff above MoPH norms; trainings for medical staff            |
| 1                  | 3. Creation of a hospital-based M&E team to follow-up progress of activities; frequent facility readiness surveys |
| idHSS catchment    | 4. Supply chain management to reduce stock-outs, management of hospital pharmacy                             |
| 4 (2014 to 2016)   | 5. Cost of outpatient and inpatient care fully covered for referred patients (district hospital and tertiary care outside Ifanadiana) |
| 5 (2017 to 2018)   | 6. Creation of a joint MoPH-PIVOT executive committee for hospital management and transparency; subcommittees for specific projects |
| Health centres     | 1. Infrastructure renovations, provision of medical and non-medical equipment; implementation of IMCI and malnutrition protocols for every child under 5 years of age |
| Total Ifanadiana:  | 2. Staffing of CSBs above MoPH norms; frequent trainings for medical staff                                    |
| 13                 | 3. Joint MoPH-PIVOT training and supervision to improve HMIS data quality                                       |
| idHSS catchment    | 4. Supply chain management, training and reduction of stock-outs;                                              |
| 4 (2014 to 2016)   | 5. Essential medicines and consumables provided free of charge to all patients                                   |
| 5 (2017 to 2018)   | 6. Close collaboration with district health managers for the planning and implementation of activities               |
| Community health   | 1. Construction of 43 community health posts by community, with PIVOT support; implementation of IMCI and malnutrition protocols for every child under 5 years of age |
| Total Ifanadiana:  | 2. Training, coaching and monthly supervision of community health workers by mobile teams of trained nurses (14 nurses for ~86 CHWs) |
| 195 fokontany idHSS| 3. Joint MoPH-PIVOT training to improve HMIS data quality                                                       |
| catchment:         | 4. Monthly provision of MNCH medicine stocks to CHWs and follow-up of medicine stock use                     |
| 21 (2014 to 2016)  | 5. Cost of MNCH medicine stocks fully covered by PIVOT; financial incentives to CHWs for stock management and attendance to supervisions (~US$4 per month) |
| 43 (2017 to 2018)  | 6. Community engagement and participation (eg, building health posts)                                         |

- Building blocks of HSS: (1) Service delivery, (2) Health workforce, (3) Health information systems, (4) Medicines and supplies, (5) Financing and (6) Leadership and governance.
- †Implemented by PAUSENS programme (World Bank)
- ‡Implemented by Mikolo programme (USAID)

CHW, community health workers; HMIS, Health Management and Information Systems; HSS, health system strengthening; idHSS, integrated district-level health system strengthening; IMCI, integrated management of child illness; M&E, Monitoring and Evaluation; MNCH, maternal, newborn and child health; MoPH, Ministry of Public Health.

district-level health system strengthening intervention (referred to as idHSS) carried out by the MoPH-PIVOT partnership is guided by existing MoPH policies and is implemented across all three levels of care in the district (community, health centre and hospital). This intervention (summarised in table 1 and online supplemental table S1) is structured through the integration of clinical programmes, health system ‘readiness’ and information systems. The clinical programmes include child health, with a focus on malnutrition and integrated management of child illness; maternal...
and reproductive health; social support; and infectious disease programmes, with a focus on tuberculosis, malaria and emerging diseases. Clinical programmes are implemented throughout community health sites, primary healthcare centres and district hospital (details can be found in33).

Readiness includes infrastructure and sanitation, staffing and equipment to improve the quality of care; procurement systems; an ambulance network; trainings, frequent supervision and coaching of health staff. As part of the vision for UHC to increase healthcare access and reduce financial vulnerability, user fees are removed at all levels of care via payments from PIVOT to health facilities on behalf of patients (Section S1 and online supplemental table S2), and social support is provided to vulnerable patients. The core activities in the first 3 years (2014 to 2016) covered four communes with approximately one-third of the population of Ifanadiana (referred to as ‘idHSS catchment’). In 2017, idHSS activities expanded to a fifth commune. Some activities such as medical staff recruitment and strengthened information systems spanned the whole district (online supplemental table S1). The idHSS intervention, initially modelled after an earlier experience in HSS in Rwanda,34 35 is being tailored over time in collaboration with the government to respond to coverage gaps and intervention deficiencies identified through an iterative learning process that uses health system and population-level data (online supplemental table S1).

In addition to the idHSS intervention, during this period, the population of Ifanadiana benefited from two other notable programmes that covered both the idHSS catchment area and the rest of the district (referred to as ‘control catchment’). The PAUSENS project, funded by the World Bank, provided a basic package of services free of charge in all 13 CSB2 through a voucher system to health centres. The Mikolo project, funded by USAID, provided support to a network of 150 CHWs in Ifanadiana and validated for Madagascar during previous national health surveys in the country, was responsible for data collection, survey coordination, training and oversight. A two-stage sample was used, which stratified the district by the initial idHSS and control catchments. Eighty clusters, half from each stratum, were selected at random from enumeration areas mapped during the 2009 census, and households were then mapped within each cluster. Twenty households were selected at random from each cluster.

The first wave of data collection was conducted between April and May of 2014. Individual face-to-face interviews were conducted with women aged 15 to 49 years and men aged 15 to 59 years (usual residents or visitors) in 1522 of the sampled households (95.1% response rate). The original 1600 households were revisited between August and September of 2016 and again between April and May of 2018; any missing or refused households were replaced with others from the same cluster using a predefined random replacement list. Overall, 1514 households were interviewed during the first follow-up survey in 2016 (94.6% response rate) and 1512 during the second in 2018 (94.5% response rate). All residents, including children, had weight and height measured (or length in the case of infants). Data collected in the questionnaires included, among others, household composition (size, genders and ages); indicators of socio-economic status (education, employment and household durable assets); illness in last 30 days for all household members and care seeking for illness; preventive behaviour (bed net ownership, access to water and sanitation); women’s reproductive history and care seeking behaviour for reproductive health; children’s health, development and care seeking for illness; adult, maternal and child mortality.

French and Malagasy questionnaires used in the cohort, as well as data collection protocols, were standardised and validated for Madagascar during previous national surveys carried out by INSTAT. All adults (≥15 years) provided verbal consent for the in-person interview and anthropometric measurements. Parents or guardians provided consent for children ≤5 years of age. INSTAT provided survey data to the investigators with all individual identifiers removed and with geographical information at the cluster level. Spatial boundaries of each cluster were made available to the investigators and are stored separately; this information will not be published or shared publicly. Further details on data collection and survey design are available in.33

**Patient and public involvement**

Patients or the public were not involved in the design, conduct, reporting or dissemination plans of our research.

**Population survey data: the IHOPE cohort**

A longitudinal cohort study known as the Ifanadiana Health Outcomes and Prosperity longitudinal Evaluation (IHOPE), or IHOPE cohort, was initiated in 2014 to obtain demographic, health and socio-economic information from a representative sample of 1600 households in Ifanadiana district over time.32 Questionnaires were mostly adapted from the Demographic and Health Survey (DHS).36 The Madagascar National Institute of Statistics (INSTAT), which implements all major national health surveys in the country, was responsible for data collection, survey coordination, training and oversight. A two-stage sample was used, which stratified the district by the initial idHSS and control catchments. Eighty clusters, half from each stratum, were selected at random from enumeration areas mapped during the 2009 census, and households were then mapped within each cluster. Twenty households were selected at random from each cluster.

The first wave of data collection was conducted between April and May of 2014. Individual face-to-face interviews were conducted with women aged 15 to 49 years and men aged 15 to 59 years (usual residents or visitors) in 1522 of the sampled households (95.1% response rate). The original 1600 households were revisited between August and September of 2016 and again between April and May of 2018; any missing or refused households were replaced with others from the same cluster using a predefined random replacement list. Overall, 1514 households were interviewed during the first follow-up survey in 2016 (94.6% response rate) and 1512 during the second in 2018 (94.5% response rate). All residents, including children, had weight and height measured (or length in the case of infants). Data collected in the questionnaires included, among others, household composition (size, genders and ages); indicators of socio-economic status (education, employment and household durable assets); illness in last 30 days for all household members and care seeking for illness; preventive behaviour (bed net ownership, access to water and sanitation); women’s reproductive history and care seeking behaviour for reproductive health; children’s health, development and care seeking for illness; adult, maternal and child mortality.

French and Malagasy questionnaires used in the cohort, as well as data collection protocols, were standardised and validated for Madagascar during previous national surveys carried out by INSTAT. All adults (≥15 years) provided verbal consent for the in-person interview and anthropometric measurements. Parents or guardians provided consent for children ≤5 years of age. INSTAT provided survey data to the investigators with all individual identifiers removed and with geographical information at the cluster level. Spatial boundaries of each cluster were made available to the investigators and are stored separately; this information will not be published or shared publicly. Further details on data collection and survey design are available in.33

**Health system utilisation data**

We obtained data for the period of January 2013 to December 2018 from the MoPH for 13 CSB2 in Ifanadiana
district on the number of new individuals per month attending each health centre for outpatient consultations or maternal care. We excluded two CSBs that did not exist for this 6-year period (built in November 2016 and April 2018), as well as the six CSB1 in the district because they lack medical doctors and provide a more limited number of health services. Given that the idHSS intervention started in early 2014 (shortly after the baseline survey) and affected utilisation rates that year, we included health system utilisation data since 2013 in order to have a true baseline before the idHSS intervention. These data were available from the health centres’ monthly reports to the district (RMA), which are aggregated from the health centres’ registers every month by MoPH staff. As a component of the idHSS intervention, data quality was maintained through joint MoPH–Pivot supervisions carried out every 3 months at a subset of health centres to compare RMA values with registry data (see38 for more details). Starting in May 2015, the MoPH changed the estimation and reporting of outpatient utilisation rates. Thus, all subsequent utilisation data were gathered directly from the registers to ensure consistent estimates throughout the 2013 to 2018 period. Information on total catchment population for each health centre was obtained from official MoPH records. Consistent with MoPH estimates, catchment population of children under 5 years of age, expected number of pregnant women and expected number of deliveries were set at 18%, 4.5% and 4% of the total catchment population, respectively. Although official population data are sometimes deemed inaccurate, we previously showed that estimating catchment populations using available data for our district from other recognised sources such as WorldPop39 did not change the results of per capita utilisation rates analyses.38

### Analysis of coverage and mortality rates from IHOPE cohort data

Under-five mortality at the population-level was estimated using the synthetic life-table method for DHS surveys.40 Under-five mortality was defined as the probability of death before age 60 months per 1000 children born alive. For each survey wave, we used information from the 5 years prior to the survey, which comprised a sample of 4063 children for 2014, 4037 children for 2016 and 3788 children for 2018. From these estimates, absolute and relative changes per year for each indicator and catchment area were estimated in univariate linear models, and these were used to estimate the difference over time between the two areas. In addition to these cross-sectional estimates, the difference in under-five mortality for the 2514 children followed-up over the 4 years was also assessed in each area. From this longitudinal analysis, incidence rates of death per person-year in children under 5 years of age were calculated using a Poisson regression.

Coverage indicators (see list in table 2 and online supplemental table S3) were estimated using standard definitions for DHS surveys.40 Vaccination coverage was defined as the proportion of children aged 12 to 23 months who received all recommended vaccines (three doses of polio and DTP, one dose of BCG and measles). Access to treatment was estimated as the proportion of children under 5 years of age who were ill with fever, acute respiratory infection or diarrhoea in the 2 weeks prior to the survey and sought medical treatment (at a hospital, health centre or community health worker). In order to measure the effect of the idHSS intervention on maternal health service coverage, indicators were estimated for the last pregnancy during the 2 years preceding the survey. In addition, to track a summary indicator of maternal, newborn and child health (MNCH) coverage, we estimated co-coverage indices (three interventions or less; five interventions or more) for women and children under 5 years of age and a modified version of the composite coverage index (CCI)41 that included all standard maternal and child interventions except for family planning, which was not available in the 2014 survey.

Coverage and mortality indicators were calculated for 2014, 2016 and 2018 both in the idHSS catchment (which changed over time) and in the control catchment (the rest of the district). Yearly changes in coverage between the idHSS and control catchments were modelled from individual-level data using multivariate logistic mixed regressions that included a random intercept at the cluster level, using the following formula:

$$y_{ij} = \alpha + \beta_1 \text{year}_i + \beta_2 \text{catchment}_i + \beta_3 \text{exposure}_i + b_i + \epsilon_{ij}$$

Where $y_{ij}$ is the average coverage for year and cluster; catchment reflects whether the household of the individual was part of the initial idHSS catchment to account for baseline differences in these two areas; exposure reflects the number of years of exposure of the cluster to the idHSS intervention to account for the expanding idHSS catchment; $\beta_1$ is the yearly change in the control catchment, $\beta_2$ is the baseline difference in utilisation between the initial intervention catchment and the control catchment and $\beta_3$ is the yearly change associated with the idHSS intervention; $b_i$ and $\epsilon_{ij}$ are the random intercept and error associated with each cluster, respectively. Results were reported as adjusted OR, and as predicted yearly change (using only the model’s fixed effects). The 95% CIs for yearly changes were estimated through parametric bootstrap (400 simulations per indicator). Data were entered into CSPro and all analyses were done using R statistical software, V.3.1.242 and R-package lme4 with the exception of population-level mortality rates and associated 95% CIs, which were calculated with SAS 9.3,43 and the observed under-five mortality incidence rate ratios, which were calculated with Stata, V.15.14 Changes of coverage in the initial idHSS catchment area (four communes) and in the control catchment were also estimated and compared using difference-in-difference analyses (online supplemental table S4) for consistency with analyses in our previous 2-year impact evaluation.31 Sampling weights that adjusted for unequal probability of selection...
due to stratification and non-response were calculated for household, women’s and men’s surveys. Estimates were obtained using survey commands available in R-package `survey` and applicable sampling weights.45

### Analysis of geographical and economic inequalities in healthcare coverage from IHOPE cohort data

First, changes in the geographical distribution of coverage over time in Ifanadiana were assessed for each indicator. For this, average values for the 80 geographical clusters in the IHOPE cohort were estimated, each of which included 20 households and approximately 100 individuals. Then, given the spatial location of each cluster, a raster surface of the whole district was obtained to improve visualisation of results. This was done through inverse distance weighted interpolation on the empirical curve, and was calculated using R-packages `spdep` and `gstat`.

Second, trends in economic and geographical inequalities in the idHSS catchment were assessed for each coverage indicator. To estimate economic inequalities, a household wealth index was calculated through a principal components analysis of household assets following standard DHS methods.40 To estimate geographical inequalities, the Open Source Routing Machine (OSRM) engine was used to accurately estimate the shortest path distance between the villages in each cluster and the nearest health centre. For this, we had previously mapped the entire district of Ifanadiana on OpenStreetMap, resulting in over 23,000 km of footpaths and 5000 residential areas mapped (see46 for details). For each indicator, we estimated wealth-specific and geographic-specific averages (bottom two quantiles vs top three quantiles) as well as composite indicators of inequality, such as relative concentration index and slope index of inequality.47

The relative concentration index (RCI) is a measure of relative inequality based on the concentration curve, a plot of the cumulative distribution of each coverage indicator (y-axis) in the population ranked by wealth or geography (x-axis) and adjusted by survey weights.47 The RCI is defined as twice the area between the line of equality (45° diagonal line) and the indicator’s concentration curve, and was calculated using R-package `decomp`.48 The slope index of inequality (SII) is a measure of absolute inequality that represents the difference in coverage between the highest and the lowest values of the wealth or geography rank (normalised between 0 and 1). It was

| Indicator | Coverage at baseline - Intercept | Baseline differences in initial idHSS catchment versus control - OR (95% CI) | Change per year - OR (95% CI) | Additional change per year of idHSS intervention - OR (95% CI) |
|-----------|--------------------------------|----------------------------------------------------------------|-----------------------------|-------------------------------------------------|
| Co-coverage index (5+ interventions) | 0.2 (0.2 to 0.4)** | 1.6 (0.7 to 3.7) | 1.1 (1.0 to 1.3) | 1.0 (0.8 to 1.3) |
| All recommended vaccines (12–23 months) | 0.3 (0.2 to 0.4)** | 1.1 (0.6 to 2.3) | 1.1 (1.0 to 1.2) | 1.2 (1.0 to 1.5) |
| Oral rehydration therapy for diarrhoea (<5 years) | 0.3 (0.2 to 0.4)** | 1.9 (1.1 to 3.1)** | 1.0 (0.9 to 1.1) | 1.2 (1.1 to 1.4)** |
| Care seeking for fever (<5 years) | 0.3 (0.2 to 0.4)** | 2.3 (1.3 to 4.1)** | 1.0 (0.9 to 1.1) | 1.0 (0.8 to 1.3) |
| Maternal care (last birth last 2 years) | 0.2 (0.2 to 0.3)** | 1.9 (1.0 to 3.6)** | 1.0 (0.8 to 1.1) | 1.3 (1.0 to 1.7)** |
| Antenatal care (1+ visit with skilled provider) | 0.8 (0.7 to 0.9)** | 1.3 (0.6 to 2.8) | 1.2 (1.1 to 1.4)** | 1.1 (0.9 to 1.3) |
| Birth delivered at public health centre | 0.1 (0 to 0.1)** | 2.0 (0.9 to 4.6) | 1.3 (1.1 to 1.4)** | 1.0 (0.9 to 1.3) |
| Birth delivered by caesarean section | 0 (0 to 0)** | 6.2 (0.6 to 61.8) | 1.4 (0.8 to 2.5) | 0.8 (0.4 to 1.6) |
| Postnatal care (within 48 hours with skilled provider) | 0.1 (0 to 0.1)** | 2.2 (1.0 to 5.1) | 1.2 (1.1 to 1.4)** | 1.0 (0.8 to 1.2) |
| All household members | Individual care seeking for illness in last 4 weeks† | 0.1 (0.1 to 0.2)** | 1.0 (0.6 to 1.8) | 1.2 (1.1 to 1.3)** | 1.4 (1.2 to 1.6)** |

ARI, acute respiratory infection; idHSS, integrated district-level health system strengthening; MNCH, maternal, newborn and child health.
Changes in coverage indicators and mortality rates

After 4 years of intervention, under-five mortality decreased in the original idHSS catchment from 104 (95% CI 73 to 135) at baseline to 89 deaths (95% CI 57 to 120) per 1000 live births, an average annual relative reduction of 4% (table 3). Infant mortality decreased from 66 (95% CI 40 to 92) to 59 deaths (95% CI 38 to 81) per 1000 live births, an average annual relative reduction of 4% (table 3). Infant mortality decreased from 66 (95% CI 40 to 92) to 59 deaths (95% CI 38 to 81) per 1000 live births, an average annual relative reduction of 4% (table 3). Infant mortality decreased from 66 (95% CI 40 to 92) to 59 deaths (95% CI 38 to 81) per 1000 live births, an average annual relative reduction of 4% (table 3).

*Estimations use data from the 5 years prior to each survey to allow for sufficient sample sizes.

In order to build explicit information feedback loops between the impact evaluation and programme implementation, we developed a user-friendly online application to facilitate the use of the idHOPE cohort database and inequalities presented in this manuscript, making the visualisation of results flexible and easily accessible by programme managers and decision-makers. This application is called the PIVOT dashboard (https://research.pivot-dashboard.org/).

An analysis of healthcare utilisation from health centre data

For each health centre, we calculated the annual average in per capita utilisation rates for maternal health services (antenatal care, first and fourth visit; deliveries, and postnatal care) and outpatient care for any illness (all patients and children under 5 years of age). We estimated annual changes during the 2013 to 2018 period for health centres in the idHSS and control catchments using mixed logistic regression models equivalent to the analyses of survey data described above (with a random intercept for each health centre).

Development of a web interface for operational use of cohort results

In order to build explicit information feedback loops between the impact evaluation and programme implementation, we developed a user-friendly online application to facilitate the use of the idHOPE cohort database and inequalities presented in this manuscript, making the visualisation of results flexible and easily accessible by programme managers and decision-makers. *Estimations use data from the 5 years prior to each survey to allow for sufficient sample sizes.

In order to build explicit information feedback loops between the impact evaluation and programme implementation, we developed a user-friendly online application to facilitate the use of the idHOPE cohort database and inequalities presented in this manuscript, making the visualisation of results flexible and easily accessible by programme managers and decision-makers. This application is called the PIVOT dashboard (https://research.pivot-dashboard.org/).
live births, an average annual relative reduction of 3%. Neonatal mortality decreased from 47 (95% CI 27 to 68) to 33 deaths (95% CI 16 to 51) per 1000 live births, an average annual relative reduction of 7%. In comparison, infant and neonatal mortality rates increased in the rest of the district, and under-five mortality decreased by an average of only 3%. All three mortality indicators in both areas were higher in 2018 than in 2016, but the gap in mortality rates between the original idHSS and control catchments consistently increased during this period. Differences in mortality rates over time between the two areas were not statistically significant. Complementary to results on 5-year population average mortality rates described above, analyses of incidence rates of death in the 2514 children under 5 years of age followed up between 2014 and 2018 revealed that the incidence rate was 2% per person-year in the idHSS catchment (47 deaths) and 3% per person-year in the control catchment (123 deaths). This represented an incidence rate ratio of 0.6 (95% CI 0.4 to 1.0), with a borderline statistically significantly lower incidence of deaths of children under 5 years of age in the idHSS catchment (p=0.05).

Reductions in mortality rates were accompanied with improvements in coverage indicators during this period for maternal, child and individual care (figure 1, table 2). The co-coverage index (5+ interventions), a summary index of maternal and child interventions increased by 4% annually in the idHSS catchment, nearly double than in the control catchment (figure 1). Differences between the two areas were particularly large for child coverage indicators, with annual increases in the idHSS catchment 4 to 6 percentage points higher than in the control catchment (vaccine coverage, care seeking for illnesses, ORS (oral rehydration salts) for diarrhoea, care seeking for acute respiratory infection (ARI)), except for care seeking for fever. Improvements in maternal coverage indicators were similar in the two areas for ante-natal care (1+ and 4+ visits, annual increase of 3% and 6%, respectively). However, in the idHSS catchment, the proportion of deliveries at health facilities and postnatal care within 48 hours with a skilled provider improved by 3 and 2 percentage points more than in the control catchment, respectively. Care seeking for illness in individuals of all ages increased by nearly 10% per year in the idHSS catchment, compared with only 2% in the control catchment. Despite these positive results, the uncertainty around most of these estimates was high (figure 1). After accounting for baseline differences between the two areas and the average change in the district during this period (table 2), we found that the intervention was only associated with a statistically significant yearly improvement for care seeking for child illness (OR=1.2; 95% CI 0.7 to 2.0) in the idHSS catchment.
Changes in health centre utilisation

The evolution of health centre utilisation rates in these two areas (table 4) was consistent with population-coverage results. We observed an increase in utilisation for all primary care services evaluated over the study period. However, the yearly improvement in per capita utilisation associated with the idHSS intervention was larger for outpatient consultations of individuals of all ages (OR=1.31; 95% CI 1.30 to 1.31) and consultations of children under 5 years of age (OR=1.25; 95% CI 1.23 to 1.26) than for any maternal care indicator evaluated.

Changes in geographical and economic inequalities in MNCH coverage

The spatial distribution of coverage in Ifanadiana district improved over time, especially in the idHSS catchment, but significant spatial heterogeneities remained both in the idHSS and control catchments. For instance, healthcare seeking behaviours for childhood illnesses (figure 2) was below 50% everywhere in the idHSS catchment in 2014. Rates increased to 60% to 85% across the idHSS catchment in 2016 and 2018, except for a remote area in one of the intervention communes (centre-right of the map), where populations have to travel over 4 hours by foot each way to reach the nearest health facility.46.

Figure 2 Geographical distribution of healthcare seeking behaviours for child illness, 2014 to 2018. It displays for each wave of the cohort the mean proportion of children under 5 years of age who were brought to a public provider (health centre or community health worker) when reported illness in the previous 2 weeks. Administrative limits of the HSS intervention catchment each year are shown in red. Equivalent maps for each indicator evaluated in this study are available through the accompanying Shiny App. HSS, health system strengthening.

Table 4 Model predictions of annual change in health centre utilisation associated with the idHSS intervention and in the rest of Ifanadiana district (control), 2013 to 2018

| Indicator | Per capita utilisation at baseline - intercept | Baseline differences in initial idHSS catchment versus control - OR (95% CI) | Change per year - OR (95% CI) | Additional change per year of idHSS intervention - OR (95% CI) |

behaviours for childhood illnesses remained consistently below 50% during the study period (figure 2). The idHSS intervention implemented by the MoPH-PIVOT partnership was associated with reductions in economic and geographical inequalities for most indicators assessed (figure 3, online supplemental tables S5 and S6). Annual increase in coverage in the poorest two quantiles ranged from 0.6 to 12.4 percentage points. Both absolute and relative economic inequalities were reduced for all indicators except for antenatal care (1+ and 4+ visits). The largest reductions in absolute economic inequality were observed for child vaccination and care seeking for individuals of all ages (SII change of nearly −10 per year). Results for geographical inequalities were mixed. We observed a generalised improvement in coverage for populations living further from a health centre and an associated reduction in relative geographical inequalities. However, absolute improvements in coverage were larger in populations living close to a health centre for nearly half of the indicators assessed, leading to an increase in absolute geographical inequalities (SII), with annual changes ranging from −7.1 to +7.3. The indicators with the largest reductions in absolute geographical inequalities were child vaccination coverage, antenatal care (1+ visits) and birth delivered by C-section (SII change larger than +4 per year).

Analyses of inequalities were consistent with self-reported barriers to access health facilities by individuals who did not seek care following an illness (available only for 2016 to 2018). Reported financial barriers in the idHSS catchment more than halved (from 33% to 15%), while geographical barriers remained constant at 20% of responses (figure 4). Overall, reported barriers for not accessing care decreased by more than one-third in the idHSS catchment. In contrast, reported barriers only decreased by less than 15% in the control catchment, and the percentage of responses involving financial barriers barely changed during this period, remaining at about one-third of responses.

Information loops between impact evaluation and implementation: the IHOPE dashboard Cohort results have been integral to the tailoring of the ongoing idHSS intervention, highlighting gaps in coverage or quality of care, insufficient progress in particular health programmes and potential solutions to address them. Though evaluation results are presented to managers and leadership of the MoPH-PIVOT partnership as they become available, there were inherent challenges in the routine use of this information. A user-friendly web interface is now accessible to programme managers in Ifanadiana district (figure 5), allowing visualisation of key information for over 40 coverage indicators from the IHOPE cohort for the planning and implementation of health interventions. These population-level results, available at granular temporal and spatial scales across Ifanadiana district, provide a breadth of information for iterative learning, complementary to more traditional dashboards of routine health system data. The IHOPE dashboard
Figure 4  Reported reasons for not seeking care at a health facility, 2016 to 2018. It displays the percentage of responses out of all primary and secondary reasons that household members provided when they reported being ill in the previous 4 weeks but not seeking treatment at a health facility.

includes trends in coverage over time in Ifanadiana district, comparisons by intervention catchment and by commune; changes in economic and geographical inequalities; and spatial distribution of coverage over time. Information is updated every 2 years, and the number of indicators included will be progressively

Figure 5  Web interface for operational use of cohort results by local health managers. Illustrative example of the interface available at http://research.pivot-dashboard.org/. It shows an analysis of child mortality indicators (under 5 years of age, infant and neonatal mortality) over time, in the idHSS catchment (solid line) and in the control catchment (dashed line). Top panels show trends in mortality between 2014 and 2018, while middle and bottom panels show absolute and relative change during the same period, respectively. HSS, health system strengthening; idHSS, integrated district-level health system strengthening; IHOPE, Ifanadiana Health Outcomes and Prosperity longitudinal Evaluation.
expanded to encompass most aspects of the idHSS intervention.

**DISCUSSION**

In the coming decades, low- and middle-income countries will need to allocate substantial investments to HSS and UHC in order to achieve the health-related SDGs. Yet, there is still a substantial gap in the evidence to inform this shift due to challenges in the assessment of such complex interventions, with cross-benefits at the population level.\(^5\)\(^28\) We analysed changes in healthcare utilisation, coverage and mortality in a district-representative longitudinal cohort to assess the impact of the first 4 years of an ongoing idHSS initiative in a rural district of Madagascar. Our results reveal improvements in care seeking and economic inequalities, both central goals of UHC policies. Coverage increased by more than 4% per year for all recommended vaccines, for care seeking in children and adults and for facility birth deliveries, even in the poorest economic groups. Despite improvements in all coverage and mortality indicators in the idHSS catchment, only care seeking for children and adults were statistically significantly associated with the idHSS intervention. Differences with the rest of the district for maternal care coverage and under-five mortality rates were modest and non-significant. The persistence of geographical inequalities in access to care observed in the idHSS catchment highlights potential solutions for optimising the impact of HSS interventions, such as substantial investments in outreach activities and community health. More broadly, our study highlights the value of iterative learning between HSS implementation and impact evaluation, based on the dynamic integration of data and analytics at multiple levels of a health district.

Ensuring universal access to essential maternal and child health services via UHC packages and HSS is a strategic priority of the United Nations’ Every Woman Every Child Global Strategy.\(^8\) We show that in 4 years of intervention, coverage in the idHSS catchment improved faster than what has been observed globally, catching up with the global median coverage for most indicators of child care coverage (eg, ORS for diarrhoea, care seeking for acute respiratory infections, immunisations and so on).\(^31\) The idHSS intervention had the largest effects on care seeking for illness, not only for children but also for individuals of all ages, with annual relative improvements of 30% to 40%. This has led to an annual increase in health centre utilisation associated with the idHSS intervention of 25% in children and 31% in individuals of all ages, tripling utilisation rates in the control catchment by 2018. Yet, there remained substantial gaps for most maternal care indicators as compared with global trends. For instance, despite an annual increase of over 4 percentage points in recommended antenatal care visits (4+), coverage in 2018 was 20 percentage points lower than the 73% median global coverage.\(^31\) In addition, we observed significant district-level improvements over time in prenatal, delivery and postnatal care, but the idHSS intervention was not associated with an additional increase. Similarly, annual changes in maternal care visits at health centres in the idHSS intervention were consistently lower than improvements observed for outpatient visits. Implementation of a World Bank voucher programme targeting pregnant women in the whole district and a limited focus on maternal health activities in the idHSS catchment could partly explain these trends. As the World Bank programme ends and components of the idHSS intervention are expanded to the whole district in 2020 for the UHC pilot, changes in intervention coverage will be closely tracked through the IHOPE study to inform local implementation and national policies.

We observed increases in intervention coverage for the most vulnerable population groups and associated reductions in inequalities. Coverage of maternal and child services in the poorest two quantiles increased by 2 to 10 percentage points per year, substantially higher than the 0.5% to 1.5% median increase observed for low-income countries.\(^52\) This gap remains when comparing summary indices such as the CCI in worst-off groups, as the annual improvement in the idHSS catchment (2.9%; online supplemental table S5) was nearly three times higher than the average for low-income countries.\(^55\) Our local results provide a more positive picture than equivalent national analyses in countries undergoing UHC and other health reforms, which showed mixed results in addressing wealth inequalities.\(^11–13\) While Ghana observed progressive convergence between groups,\(^12\) inequalities persisted in Kenya and Rwanda.\(^11\)\(^15\) Among all the indicators assessed in our setting, antenatal care (4+ visits) was the only one for which both economic and geographical inequalities increased. This is consistent with a recent analysis of 84 national surveys, showing that wealth inequalities for recommended antenatal care visits (4+) still persist across geographical regions.\(^19\)\(^10\)

Our study highlights the added value of integrating analyses of geographical inequalities into evaluations of UHC policies and HSS programmes to better assess their impact on remote populations. Although equity analyses are becoming commonplace, these have focussed so far on assessing inequalities in wealth, education and place of residence (rural vs urban).\(^16–15\)\(^52\)\(^55\) Impact evaluations rarely assess changes in geographical inequalities, even though it is well established that primary healthcare utilisation decreases exponentially for populations living at increasing distance of health facilities.\(^4–38\) In our setting, inequalities in geographical coverage were harder to address than economic inequalities, with half of indicators showing an increasing gap in absolute inequalities as a function of distance to a health facility. This is consistent with previous evidence suggesting that geographical barriers to primary healthcare can persist even in settings where user fees have been removed, making UHC policies insufficient to reach full population coverage of primary care services unless explicitly targeting remote
Despite improvements in health coverage and reductions in inequalities, child mortality trends observed in the idHSS catchment were lower than initially estimated in our 2-year evaluation. We observed annual reductions of under-five mortality rates comparable to national averages in the top 40% of countries tracked by the Countdown to 2015 initiative in 1990 to 2015. Decreases in neonatal mortality were larger, as the change in the idHSS catchment during this 4-year period (from 47 to 33 deaths per 1000 live births) was almost equivalent to the decrease observed in sub-Saharan Africa in nearly three decades (from 46 to 27 deaths per 1000 live births between 1990 and 2017). The gap between the idHSS catchment and the rest of the district increased for infant and neonatal mortality, as these rates increased from 2014 to 2018 in the control catchment. However, even the idHSS catchment experienced small increases in mortality rates from 2016 to 2018. It is possible that after an initial sudden impact in both coverage and mortality due to user-fee removals and other early programmes, further reductions in mortality rates may not be accomplished unless geographical coverage is improved. A pilot community health programme implementing proactive care is underway in one district’s commune and will be scaled to the rest of the idHSS catchment if shown effective. This, among other programmes addressing persistent geographical barriers in Ifanadiana, could contribute to accelerating reductions in child mortality.

The modest impacts that we observed on maternal care and child mortality indicators could be due to a range of factors related to intrinsic effectiveness of the interventions, fidelity of implementation or persistent barriers for accessing care. A key component of this study was to build feedback mechanisms between research and implementation so that results are available to programme managers for operational use. This will ensure that any issues identified during the impact evaluation can be addressed in a timely manner. Typically, experimental trials provide insights on whether a pilot intervention works using randomised controlled designs, whereas implementation research explores how, when and why the intervention works, making use of a variety of study designs, from quantitative to qualitative research. Here, we use an intermediate approach by combining a quasi-experimental design with a comprehensive set of population-level analyses at very granular spatial and temporal resolutions. Insights generated through the IHOPE cohort have influenced the design and implementation of the idHSS intervention over time. For instance, while the idHSS intervention was initially focussed on facility-based care, results on geographical access to care led to a substantial shift towards strengthening community health programmes, which is currently evolving towards proactive care delivery given persistent geographical inequalities. Similarly, lags in maternal care improvements in the idHSS catchment have pushed new efforts by the MoPH-PIVOT partnership ever since, including implementation of emergency neonatal and obstetric care trainings, distribution of equipment, incentives for pregnant women to deliver at facilities (eg, social kits and waiting homes) and outreach activities for the provision of antenatal care at the community level. Visualisation of impact evaluation results into e-health tools could help further decentralise and accelerate this process, allowing programme managers to prioritise and plan activities over time to optimise coverage of key indicators. This approach is increasingly used in global health, with prior applications for malaria surveillance and health equity.

Although frequent waves of population-level data collection allow for better granularity and important programmatic insights, the short time interval since the beginning of the idHSS intervention in combination with limitations of our quasi-experimental study design could also have prevented us from detecting significant impacts at this point. First, estimations of population-level child mortality were based on 5-year estimates to attain adequate sample sizes, leading to overlap in the mortality results, which were reported at 2-year intervals. Despite this, CIs were still wide, which may explain the inconsistent trends observed in the 4-year period. Allowing for longer evaluation periods will lead to progressively better estimates of intervention impact on mortality rates, with long-term trends less sensitive to variability in particular years. Second, we used two slightly different idHSS catchment populations in our analyses, to accommodate limitations in the methodology. While analyses of coverage and utilisation indicators allowed for changes in the idHSS catchment over time to include an additional commune in 2017, this was not possible for estimating inequalities or child mortality; these used the initial idHSS versus control catchment comparison for the whole study period. Third, the effects of HSS programmes could be non-linear (online supplemental figure S2), but given the short time frame of the study we only studied annualised linear effects. Finally, the process of implementing the idHSS intervention is not discrete and immediate, it is gradually being implemented and involves many simultaneous programmes at different levels of the health system. As a result, while we can infer an overall intervention impact, it is not possible to accurately estimate the effect of particular components of the intervention, some of which could have effects district-wide.

In conclusion, we show how the combination of a district-representative longitudinal cohort and health system data can help assess complex HSS interventions. The results demonstrate improvements in care seeking behaviours and economic inequalities linked to the early stages of an idHSS intervention in a rural district of Madagascar. Additional improvements in intervention coverage and child mortality in this context of persistent

### Table S1. Summary of the idHSS intervention carried out by the MoPH-PIVOT partnership in Ifanadiana District in 2014-2017, based upon TIDieR guidance

| **1. BRIEF NAME** | Integrated district-level health system strengthening (idHSS) initiative in Ifanadiana, Madagascar |
|-------------------|--------------------------------------------------------------------------------------------------|

| **2. WHY** | **GOAL/RATIONALE:** To create a model public health district with universal access to care aiming for broad-based population health impact on mortality. Based upon the World Health Organization’s building blocks of Health System Strengthening: 1) service delivery; 2) health workforce; 3) health information systems; 4) medicines and supplies; 5) financing; 6) leadership. |

| **3. WHAT** | **3. MATERIALS (by level of care and above enumerated building blocks)** |
|-------------|--------------------------------------------------------------------------------|

**At district hospital level**

1. **Service delivery:** Overall infrastructure upgrades and outfitting for service delivery, bringing inpatient bed capacity from 25 to 40, upgrades to waste management system, specific renovations of the emergency and triage department, pediatric unit, inpatient ward, isolation ward, and laboratory; support to specific service delivery, including emergency care and provision of a network of 3 ambulances, including 2 new fully equipped ones with 24/7 coverage and 12 PIVOT paramedics for referrals; maternal and obstetrical care; laboratory service were upgraded to include a total of 53 tests, including microscopy and GeneXpert for tuberculosis; social support evolved to support all hospitalized and vulnerable patients; launch of intensive care unit for severe acute malnutrition with complications.

2. **Health workforce:** Staffing of health workers to reach MoPH norms through joint MoPH-PIVOT hires of 7 clinicians, including a trauma surgeon and an anesthesiologist, which were integrated into the MoPH staff (long term solution); staffing supplemented further with fulltime presence of 2 PIVOT doctors and 4 nurses by end of 2017; non-clinical PIVOT staff including a team of 3 social workers, support staff (janitors, guards, etc.), a laboratory technician, and a radiology technician; ongoing mentorship and frequent trainings of medical staff in key clinical areas, such as emergency medicine and postoperative care.

3. **Health information systems:** Creation of a hospital-based M&E team to follow progress of activities and improve quality of HMIS data; implementation of a system for baseline and follow-up facility readiness surveys.

4. **Medicines and supplies:** Supply chain management and reduction of stock-outs, initially through frequent donations which evolved into a reimbursement program paired with pharmacy management training; provision of medical and non-medical equipment for service delivery, including full laboratory capacity. PIVOT became the procurement manager for the hospital pharmacy as of October 2017.

5. **Financing:** Cost of outpatient and inpatient care fully covered for patients referred by district-wide health centers and self-referred patients who necessitated urgent inpatient care (over 76,000 patients between 2014 and end of 2017); cost of referral to and care at higher levels of care (e.g. university hospital) fully covered for services not available at district hospital.

6. **Leadership:** Creation of a joint MoPH-PIVOT executive committee for hospital management and transparency; creation of sub committees for specific projects such as infection control or quality of care.

**At health center level**
(1) **Service delivery:** Overall infrastructure renovations and/or extensions for service delivery at 5 target health centers, including ensuring electricity, water, waste management/sterilization capacity, proper pharmacy conditions; provision of medical and non-medical equipment, including beds, armoires, furniture; support to launching specific service delivery of Integrated Management of Childhood Illnesses (IMCI) and malnutrition protocols for every child under 5 attending the health center; ensuring timely referrals and emergency care. Launch of supervision efforts and quality of care improvement projects with a focus on IMCI and malnutrition.

(2) **Health workforce:** Staffing through joint MoPH-PIVOT hires to bring all 13 primary care health centers up to MoPH norms (1 doctor, 1 nurse, 1 midwife, 1 dispenser, 1 support staff at each facility); 33 PIVOT-MoPH hires were integrated into the Ministry of Health staff (long term solution); at target health facilities, hiring exceeded norms and PIVOT clinicians were permanently present (~2 clinicians per health center) to implement service delivery protocols (e.g. IMCI, malnutrition); trainings for medical staff (some district-wide) such as obstetrical and neonatal care; ongoing supervision and mentorship in target centers for IMCI and malnutrition.

(3) **Health information systems:** Joint MoPH-PIVOT training and supervision to improve HMIS data quality (district-wide); implementation of system for baseline and follow-up of facility readiness surveys.

(4) **Medicines and supplies:** Supply chain management and reduction of stock-outs, initially through frequent donations which evolved into a reimbursement program paired with pharmacy management training.

(5) **Financing:** Essential medicines and consumables provided free of charge to all patients (more than 130,000 patients between October 2014 launch and end of 2017); more details of this program are available in Section S1 of the Appendix.

(6) **Leadership:** Close collaboration with district health managers for the planning and implementation of activities.

**At community level**

(1) **Service delivery:** Construction of 21 community health posts; specific service delivery in Integrated Management of Childhood Illnesses and malnutrition protocols for every child under 5, community sensitization and mass testing, urgent care, and mobile clinics with direct care provision by PIVOT clinicians every other month. In 2017 PIVOT started to support monthly supervision of CHWs at the health facilities and doubled the area of the CHW strengthening program (43 community health posts, covering 4 out of 5 communes in the idHSS catchment).

(2) **Health workforce:** 14 active CHW supervisors – PIVOT staff that are training, coaching and monthly supervision of ~86 community health workers by mobile teams of trained nurses by the end of 2017; community IMCI training provided for CHWs in all of the intervention area

(3) **Health information systems:** Joint MoPH-PIVOT training to improve HMIS data quality on community health.

(4) **Medicines and supplies:** Monthly provision and follow-up of MNCH medicine stocks, including malaria diagnosis and treatment, oral rehydration salts, NSAIDS, antibiotics and zinc.

(5) **Financing:** cost of MNCH medicine stocks fully covered; financial and non-financial incentives to CHWs and local leadership.

(6) **Leadership:** Community engagement and participation (e.g. community health posts are built by the community, with PIVOT support for roofing, painting, furniture and equipment).

**4. PROCEDURES**
All interventions were aimed at fulfilling existing Madagascar Ministry of Health protocols and standards.

### 5. WHO PROVIDED

#### At district hospital level

Ministry of Health clinicians provided the majority of service delivery. PIVOT clinicians are integrated in the hospital staff and provide direct care as any other clinician during external consultations and clinical rounds, but also carry out frequent training. Non-clinical PIVOT staff provided social support to vulnerable patients, helped manage the patient circuit to benefit from fee exemptions (registration, validation).

#### At health center level

Ministry of Health doctors and nurses provided the majority of service delivery. By MoPH norms each health center (CSB2) should have 1 doctor, 1 nurse, 1 midwife, 1 dispenser, and 1 support staff. Additional PIVOT clinicians (~2 per health facility) provided some direct care, especially for the implementation of malnutrition and IMCI protocols, but focused mostly on training and supervision.

#### At community level

Two community health workers per fokontany (a cluster of villages, lowest administrative unit) provided basic MNCH care, supervised monthly by the clinicians of their respective health center. PIVOT mobile teams of nurses provided on-site mentoring and supervision of CHWs every two months. They also provided direct care at community level during on-site supervisions for fokontany located >10 kilometers from a health center.

### 6. HOW (modes of delivery)

PIVOT employees worked in partnership with existing networks of MoPH clinicians and community health workers within existing public health facilities. Wherever possible, such as in the case of supply chain management, leadership and financing, the intervention deliberately avoids the creation of parallel systems of care.

### 7. WHERE

#### At district hospital level

The initial idHSS catchment area comprised the only district hospital, located in Ifanadiana city. Most referrals to higher levels of care (tertiary) were sent to the university hospital in Fianarantsoa (2h away by car), and some to specialized facilities in Antananarivo (capital, ~1 day by car).

#### At health center level

Full health center activities were implemented in the health centers of the five communes closest to the hospital on the district’s sole paved road (i.e. Ranomafana, Kelilalina, Ifanadiana, Tsaratanana, Antaratra); all 13 health centers in the district received trainings, staffing support to reach MoPH norms, and some access to the referral network (limited by road conditions and accessibility).

#### At community level

By the end of 2017, community activities had been rolled out in fokontany from four of the five communes within the idHSS catchment area (43 out of a total of 195 total fokontany in the district).

### 8. WHEN AND HOW MUCH

All interventions were progressively rolled out during the study period.
The earliest intervention activities implemented (starting in April-May 2014, at the beginning of the study period) included the ambulance network, staffing of health centers and district hospital, and provision of medical equipment in four communes. The renovation of health centers also began in April-May 2014 but the date of completion varied for each health facility. The renovation of the emergency and triage unit and pediatric guard at the district hospital were completed by early 2016. Removal of user fees at health centers and hospital began in October of 2014. Implementation of IMCI and malnutrition protocols at all health centers began in October 2015. Community-level activities began in November 2015 in two communes, with an expansion to four communes in February 2017. First expansion of the idHSS intervention area at health facility level to include a fifth commune in October 2017.

A costing analysis of the idHSS intervention is underway and will be published separately. Preliminary estimates suggest that the annual per capita investment of the idHSS intervention (all in-country costs of the NGO/idHSS catchment population) was about $35, which added to the investment by the MoPH and other bilateral or multilateral donors represents approximately $65 per capita.

9. TAILORING

The idHSS intervention in Ifanadiana District was initially modelled after the experience in HSS implementation by the NGO Partners in Health in several districts of Rwanda. A distinct element of the idHSS intervention was a substantial investment in information systems, monitoring, evaluation and research as core elements of the intervention. For M&E, an interactive dashboard allows the visualisation of hundreds of indicators from health system data collected at all levels of care. Key indicators are reviewed in monthly and quarterly reviews with program managers to follow-up the progress of different activities and services (e.g. utilization, quality of care). For research, the I-HOPE cohort study allows conducting impact evaluations every two years, which provides complementary population-level information such as health system coverage, quality, or mortality. Evaluation results are presented to managers and leadership of the MoPH-PIVOT partnership as they become available, but to allow the routine use of this information by program managers, an interactive web application has been developed (main text).

As a result of the iterative learning process integrated in the idHSS intervention, program implementation has been tailored over time to respond to coverage gaps and intervention deficiencies observed in Ifanadiana during monitoring, evaluation and research activities. The most notable example of this is the increasing support to community health after an initial phase where the idHSS intervention focused most of its resources on strengthening the district hospital and several health centers. The data and analyses generated by the I-HOPE cohort study (among other sources) have contributed to this shift, highlighting geographic inequalities in coverage and leading to several programs to address them. First, PIVOT has expanded its support to the community health program, both geographically and in terms of activities implemented. In 2019-2020, PIVOT is piloting the implementation of proactive community health in order to improve access to care for children under 5 years to further reduce geographic barriers in access to care within the communities. Second, the NGO and local government are building houses near health centers for mothers to arrive several days in advance of their delivery date in order to increase geographic access to safe delivery. This is part of a broader effort to improve maternal health coverage, given lags in maternal care improvements observed in the idHSS catchment. Third, PIVOT is increasing its outreach activities, such as on-site supervision of community health workers by teams of nurses (who also provide direct care during field expeditions) and is looking into progressively expanding the scope of work and professionalization of community health workers.

10. MODIFICATIONS

N/A; The intervention is progressively being implemented, as explained in section 8 (when and how much)

HOW WELL
The aim of this study was to study the evolution of geographic access to primary care in Ifanadiana District. Full details of the impact assessment are available in the main text.
Section S1. Summary of primary care user fee exemption programs in Ifanadiana

The aim of this section is to provide a comprehensive understanding of two programs that reduced financial barriers at primary care (i.e. health centers), implemented in Ifanadiana since the beginning of 2014. The two reimbursement programs explained below were implemented only in CSB2s (major health centers provide all types of primary care and are staffed with at least two trained practitioners, a doctor and either a nurse or a midwife): the PAUSENS program was implemented in all thirteen, whereas the idHSS intervention was implemented by the MoPH-PIVOT partnership only in four of those that were part of the initial catchment area (Figure S1), extending to an additional health center in 2017.

Figure S1. Geographical distribution of Health Centers in Ifanadiana District. Map displays the 19 public health centers in the district, with colors representing whether or not they benefited from each of the reimbursement programs (PAUSENS or PIVOT). The four communes that constitute the initial catchment population for PIVOT financial programs and most of its Health System Strengthening interventions are displayed in red. Some interventions span the entire district. Map was developed with ArcMap, version 10.2.2.

1. World Bank project “PAUSENS”

The project “Emergency Support to Critical Education, Health and Nutrition Services” (PAUSENS), funded by the World Bank, was implemented in 5 out of 22 regions of Madagascar to provide critical services to vulnerable populations. While the project included multiple interventions to improve nutrition, education and health (full details are available at [1]), the intervention relevant to this study was a financial program aimed at improving access to health care for children under 5 and pregnant women. The program provided a basic package of services free of charge at the health facility level for these vulnerable groups to remove out-of-pocket spending, through a voucher reimbursement system managed by three local NGOs in Ifanadiana (Taratra, Maintso an’Ala and Cafed/Fafed).
The basic package of services for pregnant women, from antenatal to postnatal care, included: prevention of mother-to-child transmission, treatment of syphilis, prevention and treatment of HIV/AIDS, supplementation with iron and folic acid, tetanus vaccination, intermittent preventive medication against malaria, and distribution of safe delivery kits. The basic package for children under 5 included: activities to promote good practices, breastfeeding and nutrition, Vitamin A supplementation, vaccinations, distribution of bed nets, treatment of diarrhea, prevention and treatment of malaria, and support to integrated management of childhood illness (IMCI), covering the full cost of treatments. The project also included trainings, support for child vaccination in remote areas, and donations to health centers to improve health care quality such as furniture, medical equipment, cellphones or solar-powered refrigerators.

Implementation of the program in Ifanadiana started in February 2014 and covered all thirteen CSB2s in the district. In each of these CSB2s, a program voucher agent would be present, and every woman attending the health center for antenatal, delivery or postnatal care (first 6 weeks), or for any children under five illness would receive a voucher from the agent. After consultation at the health center, medicines prescribed by MoPH health staff that were included in the program would then be provided free of charge through presentation of the voucher both at the dispensary and to the program agent. The patient would not disburse any money out-of-pocket for these medicines, since PAUSENS would directly reimburse the dispensary on behalf of the patients on a periodic basis. By December 2015, 55,979 patients of the target population had benefited from the program at an average cost per patient of $0.55.

2. PIVOT reimbursement program

The non-governmental organization PIVOT started activities in early 2014 in Ifanadiana, as part of a new partnership with the MoPH to strengthen the existing health system in the district. The initial catchment area where most programs were implemented covered 4 out of 13 communes. In the CSB2s of these four communes PIVOT implemented a reimbursement program, complementary to PAUSENS, aimed at improving access to health care for all patients. The program started in October 2014 and reimbursed the health center for the costs of 40 essential drugs and 20 consumables (Exhibit B) on behalf of patients of all ages that visited the health center for outpatient care. The number essential drugs was progressively expanded over the years to include about 70 drugs and consumables. No voucher is needed, the patient obtains at the dispensary the medicines and consumables used or prescribed by the health care provider, and a record is kept at the dispensary for reimbursement through the nongovernmental partner on a monthly basis. For this, an agreement was signed with the MoPH at the District level. The combination of the two financial programs in these four CSB2s virtually eliminated point-of-service payments for all patients seeking any type of primary care at the health
care center. The cost of the program was fully covered by the NGO’s budget, with resources obtained mostly through grants and donations from philanthropic foundations and individuals.

Table S2. List of essential drugs and consumables available for free

| Medicines                        | Consumables                          |
|----------------------------------|--------------------------------------|
| Albendazole (400 mg tab)         | Tongue depressor                     |
| Aminophylline (100 mg tab, 25 mg/ml inj) | Hydrochlorothiazide (25 mg tab)       |
| Amoxicillin (250 mg/500 mg gel, 250 mg/5 ml oral susp) | Hydrocortisone (100 mg inj)          |
| Amoxicillin/Clavulanic acid (125 mg/500 mg tab) | Ibuprofen (200 mg tab)               |
| Amoxicillin (500 mg gel, 500 mg inj, 1 g inj) | Lactated Ringer’s solution (500 ml)   |
| Artesunate (10 mg/ml inj)        | Lidocaine hydrochloride (2% inj)     |
| Atropine sulfate (0.25/1 mg/ml inj) | Metoclopramide (10 mg tab, 0.5 mg/ml inj) |
| Benzathine benzylpenicillin (2.4 MUI inj) | Metronidazole (250 mg tab, 5 mg/ml inj) |
| Fortified penicillin procaine (1 MUI inj) | Nifedipine (10 mg tab)               |
| Calcium gluconate (100 mg/ml inj) | Nystatin (100,000 UI tab, ointment, 30 ml oral susp) |
| Captopril (25 mg tab)            | Paracetamol (500 mg tab, 125 mg susp) |
| Ceftriaxone (1 g inj)             | Phenobarbital (50 mg tab, 40 mg/ml inj) |
| Chlorpheniramine (4 mg tab)      | Praziquantel (600 mg tab)            |
| Ciprofloxacin (500 mg tab)       | Quinine (300 mg tab, 300 mg/ml inj)  |
| Cotrimoxazole (120 mg tab, 400-80 mg tab, 200-40 mg/5 ml oral susp) | Salbutamol aerosol (100 µg/Dose, 0.5 mg inj) |
| Diazepam (5 mg tab, 5 mg/ml inj) | Oral rehydration solution (sachet)   |
| Sterile water for injection (5 ml, 10 ml) | 5% glucose solution (500 ml)       |
| Erythromycin (250 mg tab, 125 mg syrup powder) | 10% glucose solution (500 ml)      |
| Iron-folic acid (200-400 mg tab) | Normal saline solution (500 ml)     |
| Furosemide (40 mg tab, 10 mg/ml inj) | Tetracycline (1% ointment, 250 mg tab) |

Tab = tablet; inj = injectable; susp = suspension;
Table S3. Model predictions of annual change in coverage associated with the HSS intervention and in the rest of Ifanadiana district (RoD) for the complete list of indicators, 2014-2018. Model details are available in the main text (Methodology section).

| Indicator | Coverage at baseline - Intercept | Baseline differences idHSS vs. Control - OR (95% CI) | Change per year - OR (95% CI) | Additional change per year of idHSS intervention - OR (95% CI) |

Table S4. Changes in coverage in the initial idHSS catchment area and the rest of the district (control), 2014-2018 for the complete list of indicators. This analysis does not take into account the extension of the HSS catchment to a new commune in 2017, and assesses impact using difference in differences analyses consistent with the 2-year evaluation available in Garchitorena et al. (2018).

| Indicator                                      | 2014 Catchment % Coverage (95% CI) | 2016 Catchment % Coverage (95% CI) | 2018 Catchment % Coverage (95% CI) | 2014-2018 Relative change (%) | 2014-2018 Absolute change (%) |

1 Information not available for 2014; trends are estimated for the 2016-2018 period
Figure S2. Temporal change in key coverage indicators in Ifanadiana district, 2014-2018. Lines represent estimations over time for each of the 12 indicators presented in the main text, based on data described in Table S3. This analysis does not take into account the extension of the HSS catchment to a new commune in 2017. *Estimations for individual care seeking were obtained using 2016-2018 data only.
Table S5. Patterns of wealth inequality in health system coverage in initial idHSS catchment, 2014-2018.
