Factors predicting amoxicillin prescribing in primary care among children: a cohort study

Abstract

Background Antibiotic prescribing during childhood, most commonly for respiratory tract infections (RTIs), contributes to antimicrobial resistance, which is a major public health concern.

Aim To identify factors associated with amoxicillin prescribing and RTI consultation attendance in young children in primary care.

Design and setting Cohort study in Bradford spanning pregnancy to age 24 months, collected 2007–2013, linked to electronic primary care and air pollution data.

Method Amoxicillin prescribing and RTI consultation rates/1000 child-years were calculated. Mixed-effects logistic regression models were fitted with general practice (GP) surgery as the random effect.

Results The amoxicillin prescribing rate among 2493 children was 710/1000 child–years during year 1 (95% confidence interval [CI] = 677 to 744) and 780/1000 (95% CI = 745 to 816) during year 2. During year 1, odds of amoxicillin prescribing were higher for boys [adjusted odds ratio (aOR) 1.36, 95% CI = 1.14 to 1.61], infants from socioeconomically deprived households [aOR 1.36, 95% CI = 1.00 to 1.86], and infants with a Pakistani ethnic background [with mothers born in the UK [aOR 1.44, 95% CI = 1.06 to 1.94] and outside [aOR 1.42, 95% CI = 1.07 to 1.90)]. During year 2, odds of amoxicillin prescribing were higher for infants with a Pakistani ethnic background [with mothers born in the UK [aOR 1.46, 95% CI = 1.10 to 1.94] and outside [aOR 1.56, 95% CI = 1.19 to 2.04]] and those born <39 weeks gestation [aOR 1.20, 95% CI = 1.04 to 1.40]. Additional risk factors included caesarean delivery, congenital anomalies, overcrowding, birth season, and childcare attendance, with GP surgery explaining 7%–9% of variation.

Conclusion Socioeconomic status and ethnic background were associated with amoxicillin prescribing during childhood. Efforts to reduce RTI spread in household and childcare settings may reduce antibiotic prescribing in primary care.

Keywords anti-bacterial agents; drug prescriptions; drug resistance; medical record linkage; paediatrics; respiratory tract infections.

INTRODUCTION

Antimicrobial resistance is a public health emergency, to which prescribing of antibiotics contributes. In the UK most antibiotics are prescribed in primary care. Several studies have found that patient-level factors including gender, flu vaccination status, obesity, smoking, previous antibiotic receipt, and comorbidities increase antibiotic prescribing among adults. Prescribing rates also vary geographically according to area-level deprivation and the proportion of patients with comorbidities. Few studies have examined antibiotic use among children, despite a third of children aged <5 years being prescribed at least one antibiotic annually. Childhood antibiotic prescribing in the UK peaks between the ages of 1 and 4 years, and three-quarters of antibiotics prescribed to children in primary care are for respiratory tract infections (RTIs). Furthermore, antibiotic prescribing in childhood is linked with adverse health outcomes in later childhood, including asthma and obesity.

The severity of presenting illness determines the likelihood of being prescribed an antibiotic for common childhood infections. Therefore, the authors expect antibiotic prescribing rates among children to differ according to the factors that increase the risk of contracting common infections, including overcrowding and having older siblings, and factors that reduce the immune system’s ability to fight infections if exposed, such as prematurity, exposure to air pollution, and lack of breastfeeding. Furthermore, qualitative studies suggest parent–clinician communication may have an impact on childhood antibiotic prescribing. However, few studies have examined risk factors for antibiotic prescribing among children.

This study set out to establish child, family, and environmental factors that were associated with prescribing of amoxicillin to children aged <2 years, to inform antimicrobial stewardship efforts among children. In order to examine the importance of individual and primary care-level factors, the proportion of total variation in amoxicillin prescribing attributed to GP surgery-level variation was calculated.

This study focused on amoxicillin because it is the most commonly prescribed antibiotic in UK primary care. As amoxicillin is most commonly prescribed for RTIs, the risk factors associated with primary care consultation rates for RTIs were also examined.

METHOD

Data sources Data from the Allergy and Infection (ALL-IN) substudy of the Born in Bradford (BiB) cohort was used in this study. ALL-IN and BiB were associated with amoxicillin prescribing during childhood.
have been described in detail elsewhere.18,19 Briefly, pregnant women attending the Bradford Royal Infirmary for an oral glucose tolerance test (offered to all women booked for delivery at the Bradford Royal Infirmary at 26–28 weeks of pregnancy) between March 2007 and November 2010 were invited to participate in BiB. Parents completed baseline questionnaires, and details about the birth were extracted from hospital electronic maternity records. Details of congenital anomalies were obtained from a local register linked to the cohort.20 Linkage to routinely collected electronic primary care data facilitated follow-up.18

Children born from March 2008 whose parents had completed the BiB baseline questionnaires were invited to participate in the ALL-IN subcohort when aged 11 months.19 Families who agreed to participate in ALL-IN completed questionnaires at ages 12 and 24 months [completed February 2009 to September 2013]. The study used openly available data on annual average levels of fine particulate matter (≤2.5 µm, PM2.5) modelled at a 1 × 1 km grid across the UK using atmospheric transport models, from the Department for Environment, Food and Rural Affairs. PM2.5 levels were mapped to lower super output areas (LSOA, a small geographical area with an average population of 1500 people) and linked to the cohort via LSOA of the infant’s home address.21–23

Outcome variables
The primary outcome was the receipt of at least one amoxicillin prescription in primary care during the first and second year of life [see Supplementary Table S1].21 The secondary outcomes were at least one primary care consultation for upper RTIs [URTIs] or lower RTIs [LRTIs]. Diagnostic information from electronic primary care records were recorded using Read codes version 3 (CTV3; see Supplementary Table S2).24–26

Exposure variables
Table 1 summarises the source and characteristics of all outcome and exposure variables. Gestational age was coded as a binary variable for being born preterm/early-term (<39 weeks) or term (≥39 weeks). Initially 37 weeks was used to define a variable for preterm/term, however, the number of infants born <37 weeks was low (n = 112/2493, 4.5%). The five-category variable defining socioeconomic status had previously been derived from the BiB baseline questionnaire.27 Information on whether the child had spent any time in formal childcare (for example, at a nursery or with a childminder), lived in a household with ≥6 people, or had exposure to indoor household pollutants (such as mould/damp or gas cookers) was collected via parental questionnaires.

The 1 × 1 km annual ambient PM2.5 levels were mapped to the LSOA of the child’s residence at birth and age 1 year. PM2.5 exposure during pregnancy was calculated using the average PM2.5 level in the calendar year(s) covering the gestation period, weighted by the number of days’ gestation during each calendar year. PM2.5 exposure during the first year of life was also weighted by the number of days spanning each calendar year. The authors calculated annual quartiles of average PM2.5 levels across the Bradford postcode area and derived two variables to indicate weighted PM2.5 exposures at the child’s LSOA, relative to the distribution of PM2.5 exposures in the Bradford area, throughout gestation and the first year of life. As few children lived in lower pollution areas, a three-category variable was created to indicate PM2.5 exposure during pregnancy and the first year of life: first/second quartile, third quartile, and fourth quartile of BD postcode area levels. Summary statistics for the absolute levels of PM2.5 exposure corresponding to each group can be found in Supplementary Table S3.

Statistical analyses
Amoxicillin prescribing rates, and rates of consultations for URTIs and LRTIs per 1000 child-years for the first and second years of life, overall and according to each exposure variable of interest were calculated. The 95% confidence intervals (CIs) were calculated to compare rates...
Crude and mutually adjusted mixed-effects logistic regression models (‘xtlogit’ function in Stata) were fitted to determine factors associated with receiving at least one amoxicillin prescription in the first and second years of life. GP surgery was included as the random intercept to determine surgery- and child-level variation in prescribing. For the small number of children who changed GP surgery during the year, they were assigned to the surgery they were registered with for longest.

Table 1. Source and characteristics of each variable included in the analysis

| Variable                                      | Source                          | Type       | Coding                                                                 |
|-----------------------------------------------|---------------------------------|------------|------------------------------------------------------------------------|
| Primary outcome                               | Electronic primary care records | Binary     | ≥1 prescription each year: yes/no                                      |
| Secondary outcome                             | Electronic primary care records | Binary     | ≥1 consultation each year: yes/no                                      |
| Exposure                                      | Maternity records               | Binary     | Male, Female                                                           |
| Sex of infant                                 | Maternity records               | Binary     | Vaginal, Caesarean                                                     |
| Delivery mode                                 | Maternity records               | Categorical| January–March, April–June, July–September, October–December          |
| Quarter of birth                              | Maternity records               | Categorical| <39 weeks, ≥39 weeks                                                  |
| Gestational age                               | Maternity records               | Binary     | 0 congenital anomalies, ≥1 congenital anomaly                         |
| Congenital anomalies                          | Congenital anomaly register at Bradford Royal Infirmary | Binary | White British, Pakistan, UK-born, Pakistan, non-UK born, Other     |
| Ethnic background                             | BiB baseline questionnaire      | Categorical| Least deprived and most educated, Employed not materially deprived, Employed with no access to money, On benefits but coping, Most deprived |
| Socioeconomic status                          | BiB baseline questionnaire      | Categorical| Smoked during pregnancy: yes/no, 1 month, >1 month |<6 months, ≥6 months |
| Maternal smoking during pregnancy             | BiB baseline questionnaire      | Binary     | Child in formal childcare: yes/no                                      |
| Breastfeeding duration                        | ALL-IN 12-month questionnaire   | Categorical| Child in overcrowded (≥6 people) dwelling: yes/no                      |
| Childcare                                     | ALL-IN 12-month and 24-month questionnaires | Binary | Child in dwelling with visible mould/damp: yes/no                       |
| Number of people in household                 | ALL-IN 12-month and 24-month questionnaires | Binary | Gas cooking only, Gas and electric cooking, Electric cooking only |
| Household mould/damp                          | ALL-IN 12-month and 24-month questionnaires | Binary | 1st/2nd quartile, 3rd quartile, 4th quartile |

ALL-IN = allergy and infection. BiB = Born in Bradford. LRTI = lower respiratory tract infection. LSOA = lower super output area. PM$_{2.5}$ = particulate matter ≤2.5 µm. URTI = upper respiratory tract infection.

across exposures. Crude and mutually adjusted mixed-effects logistic regression models (‘xtlogit’ function in Stata) were fitted to determine factors associated with receiving at least one amoxicillin prescription in the first and second years of life. GP surgery was included as the random intercept to determine surgery- and child-level variation in prescribing. For the small number of children who changed GP surgery during the year, they were assigned to the surgery they were registered with for longest.

Based on a priori knowledge, all mutually adjusted models included ethnic background, socioeconomic status, and sex as core
Table 2. Summary of cohort characteristics, and amoxicillin prescribing rates

| Baseline characteristic | Cohort, n/N(%) | Amoxicillin prescribing rate/1000 child–years, rate (95% CI) |
|-------------------------|---------------|-------------------------------------------------------------|
|                         |               | Year 1 | Year 2 |
| Total                   |               | 710 (677 to 744) | 780 (745 to 816) |
| Sex of infant           |               |       |       |
| Male                    | 1264/2481 (50.9) | 776 (728 to 827) | 823 (774 to 875) |
| Female                  | 1217/2481 (49.1) | 642 (597 to 689) | 735 (688 to 786) |

confounders. Due to the exploratory nature of this study, additional exposure variables were selected for inclusion if they improved model fit, determined using likelihood ratio tests (P-value < 0.05). Likelihood ratio tests were conducted until no further variables improved model fit. Variables were dropped from the final model if they no longer improved fit in the fully adjusted model. Model fitting and selection procedures were repeated for having at least one URTI or LRTI consultation during the first and second years of life.

In total, 491 participants did not attend the ALL-IN 24-month follow-up. Therefore, multiple imputation using chained equations (MICE; `mi` function in Stata; 30 imputed datasets) was used to impute data for the 24-month follow-up. The MICE model included all variables in the substantive model (including outcome variables), variables from the 12-month questionnaires, additional variables predictive of missingness, and GP surgery. To avoid perfect prediction, in which categorical outcomes are predicted almost perfectly resulting in instability during estimation, all GP surgeries with <10 participants were combined into one group (n = 68/2493, 2.7%). Models for the second year of life were undertaken with and without MICE as a sensitivity analysis. All analyses were undertaken in Stata (version 16.1).

RESULTS

The cohort included 2493 singleton children. In total, 2002 (80.3%) attended the 24-month follow-up [see Supplementary Figure S1]. In total, 48.9% of all mothers had a Pakistani ethnic background (n = 1220/2493) and 43.7% were from the two most deprived socioeconomic groups (n = 1089/2493) (Table 2).

Amoxicillin prescribing

A total of 1594/2493 children (63.9%) received ≥1 amoxicillin prescription during the first 2 years of life; 42.5% (n = 1060/2493) during the first year, and 46.9% (n = 1169/2493) during the second year (see Supplementary Table S4). Prescribing rates were 710 (95% CI = 677 to 744) per 1000 child-years during their first year of life, and 780 (95% CI = 745 to 816) during the second year (Table 2). Table 3 displays the best-fitting model for amoxicillin prescribing during the first and second years of life. Compared with children of White British mothers, the odds of receiving at least one amoxicillin prescription during the first year of life were higher for children with mothers with a Pakistani ethnic background, regardless of their country of birth (UK-born Pakistani mothers: adjusted odds ratio [aOR] 1.44, 95% CI = 1.06 to 1.94; Pakistani mothers born outside UK: aOR 1.42, 95% CI = 1.07 to 1.90) and lower for those with ‘other’ ethnic backgrounds (aOR 0.70, 95% CI = 0.52 to 0.96). Infants from the most deprived households had...
Table 2 continued. Summary of cohort characteristics, and amoxicillin prescribing rates

| Characteristics collected at 12 months and 24 months | Cohort, n/N% (N=2493) | Amoxicillin prescribing rate/1000 child-years, rate (95% CI) |
|-----------------------------------------------------|------------------------|---------------------------------------------------------|
| Quartile of PM$_{2.5}$ in relation to Bradford level |                        |                                                        |
| 1st/2nd quartile                                    | 904/2493 (36.3)        | 839/2476 (33.9)                                        |
|                                                     |                        | 623 (573 to 678)                                        |
|                                                     |                        | 802 (742 to 865)                                        |

aAmoxicillin prescribing rates per 1000 child–years during the first 2 years of life for the total cohort, and summarised according to exposure categories. bPM$_{2.5}$ exposure for year 1 represents exposure in utero and year 2 to Bradford level. cIQR = interquartile range. PM$_{2.5}$ = particulate matter ≤2.5 µm.

higher odds of being prescribed amoxicillin (aOR 1.36, 95% CI = 1.00 to 1.86) compared with the least deprived.

Odds were also higher for infants who were male, had at least one congenital anomaly, born in April–June (compared with January–March), born via caesarean section, living in a household with ≥6 people, and attending formal childcare. Based on the intraclass correlation coefficient, GP surgery-level variation explained 9% (95% CI = 6 to 15) of the residual variation in amoxicillin prescribing during year 1.

The odds of receiving at least one amoxicillin prescription during the second year of life were higher for children with mothers with a Pakistani ethnic background (regardless of whether mothers were born within [aOR 1.46, 95% CI = 1.10 to 1.94] or outside of [aOR 1.56, 95% CI = 1.19 to 2.04] the UK) compared with children with White British mothers. Children born preterm/early-term and those attending formal childcare also had higher odds of amoxicillin prescribing (aOR 1.20, 95% CI = 1.00 to 1.45 and 1.45, 95% CI = 1.12 to 1.87, respectively).

GP surgery-level variation explained 7% (95% CI = 4 to 11) of the residual variation in amoxicillin prescribing during year 2.

No significant associations were observed between amoxicillin prescribing and maternal smoking during pregnancy, breastfeeding duration, nor exposure to environmental PM$_{2.5}$, household mould or damp, or household gas cooking during either year. Model results based on complete cases were comparable (see Supplementary Table S5).

### DISCUSSION

#### Summary

This study found that 42.5% (n = 1060/2493) of children were prescribed amoxicillin at least once during their first year of life and 46.9% (n = 1169/2493) during their second year.

Having a mother with a Pakistani ethnic background, irrespective of their country...

... continued

Table 3. Associations between exposures and amoxicillin prescribing during the first 2 years of life.
of birth, and childcare attendance were associated with amoxicillin prescribing across both years. Socioeconomic status, birth characteristics, and household overcrowding were significantly associated with amoxicillin prescribing during the first year only, whereas prematurity was significantly associated with amoxicillin prescribing during the second year only. Less than 10% of the total variance was attributed to GP surgery-level variation in amoxicillin prescribing.

Ethnic background and childcare attendance were significantly associated with having at least one primary care consultation for URTIs and LRTIs. Breastfeeding status was associated with URTI consultation attendance only, whereas socioeconomic status, congenital anomalies, and delivery mode were associated with LRTI consultation attendance only. In total, 11%–15% of the variation in the probability of attending at least one RTI consultation was attributed to GP surgery-level variation.

**Strengths and limitations**

A strength of this study is the comprehensive analysis of risk factors for amoxicillin prescribing, enabled by linking rich, longitudinal questionnaire data to routinely collected maternity and primary care records, and air pollution data. The ethnic diversity of the BiB cohort makes it particularly well suited to study ethnic differences in child health outcomes.

However, first, the data include children growing up in Bradford, and a limitation is therefore that this may not be representative of all children in England. Second, some environmental exposures were collected by parental report and may be subject to recall bias. Third, the indications for antibiotic prescribing were not examined, as these are inconsistently recorded in primary care.29 Further, this study focused on prescribing in primary care, excluding prescribing for more severe indications in hospitals.2 Lastly, the prescribing data were collected between 2008 and 2013, before the development of the UK 5-year antimicrobial resistance strategy to reduce overprescribing of antibiotics.2 Despite these limitations, these data are well suited to provide new insights on amoxicillin prescribing patterns among children in England.

**Comparison with existing literature**

Rates of amoxicillin prescribing in the current study are considerably higher than previous estimates, which may reflect the characteristics of the BiB cohort (see Supplementary Table S8).3,6 These findings of an increased likelihood of amoxicillin prescribing for more deprived children and children with mothers with a Pakistani ethnic background mirror findings in adults.4,5,19 Ethnic differences in prescribing may reflect differences in the severity of presenting illness, which is a key determinant for antibiotic prescribing, or differences in population mixing, parental expectation, or clinician response.30 Increased odds of amoxicillin prescribing during the first year of life for the most deprived children was observed.

### Table 3 Continued. Associations between exposures and amoxicillin prescribing during the first 2 years of life*

| Variable         | Crude (n = 2450) | Mutually adjusted (n = 2450) | Crude (n = 2476) | Mutually adjusted (n = 2476) |
|------------------|-----------------|-----------------------------|-----------------|-------------------------------|
| Cooking type     |                 |                             |                 |                               |
| Electric cooking only | 1.00 [ref]      | —                           | 1.00 [ref]      | —                             |
| Electric and gas cooking | 1.14 (0.84 to 1.56) | —                           | 1.18 (0.84 to 1.66) | —                             |
| Gas cooking only | 1.17 (0.90 to 1.54) | —                           | 1.40 (1.05 to 1.86) | —                             |
| Intra-GP surgery correlation coefficient | 0.09 (0.06 to 0.15) | —                           | 0.07 (0.04 to 0.11) | —                             |

*Crude and mutually adjusted models for amoxicillin prescribing during the first and second years of life. All models included GP surgery as the mixed-effect. Mutually adjusted models were adjusted for the mother’s ethnic background, socioeconomic status, and infant sex a priori, as well as: (a) first year of life: congenital anomalies, gestational age, quarter of birth, delivery mode, breastfeeding duration, formal childcare attendance, household mould or damp, and household overcrowding; (b) second year of life: congenital anomalies, gestational age, delivery mode, breastfeeding duration, $PM_{2.5}$ exposure, and formal childcare attendance.19 Models for year 2 include variables imputed using multivariate imputation.17 The median and IQR for the absolute $PM_{2.5}$ levels corresponding to each quartile are displayed in Supplementary Table S3. OR = odds ratio. $PM_{2.5}$ = particulate matter ≤2.5 µm. ref = reference.

socioeconomic differences were also observed in GP consultation attendance for LRTIs but not URTIs, suggesting infection severity differs by socioeconomic background. The socioeconomic disparity may be more significant than the current study’s results suggest, as poorer BiB mothers are less likely to consult primary care once health status is taken into account.

Socioeconomic differences were found to be more profound for LRTI consultations compared with amoxicillin prescribing, which may indicate that antibiotic prescribing guidelines reduce socioeconomic differences in prescribing, but not incidence of infection.

Primary care physicians play a vital role in reducing antibiotic prescribing. A modest but significant variation in amoxicillin prescribing was identified between practices [7%–9%]. This is smaller than previous estimates, which range from 32.0% to 65.0%.

However, previous studies have included data from across England, whereas the GP surgeries in this study all reside within the Bradford District and Craven Clinical Commissioning Group. Residual variation in antibiotic prescribing may reflect differences in provider services and prescribing practices, or differences in health need. This study also found higher variation in childhood RTI consultation attendance between GP surgeries, hinting that GP surgery-level variation in prescribing may be driven by differences in health need or individual access to services, rather than the GP surgery’s prescribing practices. Although previous studies suggest that targeting physician behaviour can reduce antibiotic prescribing, these findings highlight the importance of interventions at the population level. Further research considering detailed individual-level characteristics and indicators of infection risk (including overcrowding and childcare attendance) would determine where population-level antimicrobial stewardship efforts are best targeted.

Surprisingly, associations between maternal smoking or outdoor air pollution and RTI consultation attendance or amoxicillin prescribing were not observed. Regarding maternal smoking, this may be unique to the Bradford population because of the disparity between smoking habits observed between mothers of White British and Pakistani ethnic background. Furthermore, self-report of maternal smoking may not represent true behaviours; research has shown that mothers from less deprived areas are less likely to report their smoking during pregnancy. PM$_{2.5}$ has previously been found to increase the risk of URTIs and LRTIs. However, given that small effect sizes are expected, larger studies over broader geographical areas with greater variation in PM$_{2.5}$ exposure are required to address its role in RTIs and antibiotic prescribing.

Environmental exposures to newly available national primary care dispensing data could aid in these studies.

Implications for research and practice
These findings highlight the need for policies addressing the population-level inequalities associated with RTIs when addressing antimicrobial stewardship efforts among children, particularly ethnic background and socioeconomic status. Primary care networks, through which primary care practices link with other health and social care providers, provide an opportunity for GPs to promote handwashing and improved ventilation in homes (particularly those that are overcrowded) and childcare settings to prevent the spread of infection. Partnerships with pharmacies and voluntary sector organisations, for example, could help facilitate these efforts. Furthermore, this study found that children who were breastfed for <1 month were more likely to attend consultations for URTIs. There are useful published resources to aid GPs when providing breastfeeding support, including those published by the UK GP Infant Feeding Network. Primary care networks could also play a role in linking primary care to local breastfeeding support groups. Larger, national studies investigating the effect of environmental exposures on childhood respiratory health and antibiotic prescribing are recommended.
