Keywords: quantum information, quantum causal structures, composition of processes, quantum foundations

Abstract

A quantum process encodes the causal structure that relates quantum operations performed in local laboratories. The process matrix formalism includes as special cases quantum mechanics on a fixed background space-time, but also allows for more general causal structures. Motivated by the interpretation of processes as a resource for quantum information processing shared by two (or more) parties, with advantages recently demonstrated both for computation and communication tasks, we investigate the notion of composition of processes. We show that under very basic assumptions such a composition rule does not exist. While the availability of multiple independent copies of a resource, e.g. quantum states or channels, is the starting point for defining information-theoretic notions such as entropy (both in classical and quantum Shannon theory), our no-go result means that a Shannon theory of general quantum processes will not possess a natural rule for the composition of resources.

1. Introduction

Experimental tests with elementary quantum systems, most notably Bell tests, radically challenge the very notions of physical reality and cause-effect relations \cite{fri99,clt07}. Notwithstanding such fundamental novel effects, quantum mechanics still assumes a definite causal order of events. Namely, given two events, i.e. two operations performed locally in two quantum laboratories, say $A$ and $B$, we always assume that they are either time-like separated, hence, $A$ cannot signal to $B$ or vice versa, or they are space-like separated, hence, they cannot signal in either direction.

Motivated by the problem of quantum gravity, operational formalisms have been proposed for computing the joint probabilities for the outcome of local experiments, without the assumption of a fixed space-time background \cite{bbr02,bbr04,bbr05,bbr06,bbr07}. \textit{Process matrices} \cite{bbr07} are introduced as the most general class of multilinear mappings of local quantum operations into probability distributions. The process matrix formalism provides a unified description of causally ordered quantum mechanics (quantum states and quantum channels), but also includes experimentally relevant non-causal processes such as the quantum switch \cite{bs14,bs15,bs16}. Furthermore, the formalism predicts novel and potentially observable phenomena, such as the violation of so-called \textit{causal inequalities} \cite{bbr07,bs14,bs16,bs17}. Moreover, it has been proven that such processes are able to provide advantages for quantum information processing tasks, both for computation and communication \cite{bs15,bs17,bs18,bs19,bs20,bs21,bs22,bs23,bs24}. One would, then, expect that a theory of information can be developed also for processes. Such a theory would deal with, e.g., rates of information compression and communication, i.e. a process-analog of the classical and quantum Shannon theory. A fundamental assumption in classical and quantum Shannon theory \cite{sh28,sch38} is the availability of multiple independent copies of a resource (for example a classical source of random variables, a quantum state, or a channel), which is at the basis of the definition of information-theoretic entropy, i.e. Shannon or von Neumann entropy. To be more concrete, in the example of Schumacher’s compression \cite{sch95,sch96}, the optimal data compression of $n$ samples of an independent and identically distributed quantum source $\rho$ into $nS(\rho) + \delta$ qubits (with $\delta \to 0$ for $n \to \infty$), and the subsequent transmission, can be achieved only if the sender can act globally on multiple copies of the quantum state in which the information is encoded.

A natural question then arises, namely, whether a process matrix can be understood as a resource available in multiple (possibly identical) copies to experimenters, similarly to the example of Schumacher’s compression above. Answering this question will provide us with deeper insight into the nature of process matrices. For instance, if we consider an experimental realization of a process, e.g. consisting of a sequence of optical elements as in photonic experiments [10, 11], one can easily imagine that it is possible to create two identical copies of the setup, and share them among the two parties. Alternatively, if one imagines that a process matrix does not only represent an experimental setup, but also the space-time structure [28–30], then it is harder to imagine how two ‘copies of spacetime’ may be shared between the two parties. More generally, such a composition rule should not be only about identical copies, but it should also allows us to combine different processes.

It is important, at this point, to distinguish two different scenarios and their corresponding composition rules. On the one hand, one may simply ask what is the rule for composing different processes independently, with the requirement that experimenters act locally on each copy of the process; this rule is given by the tensor product. On the other hand, going back to the example of Schumacher’s compression protocol, one may require that a single experimenter (or many experimenters for multipartite systems) has access to multiple copies of a process, in order to perform a protocol that involves global operations. We will see that the latter notion is incompatible with the definition of a process.

For quantum states, quantum channels, or for any collection of processes with the same definite causal order [31, 32], the parallel composition can be described by the tensor product. However, it is known that a parallel composition of process matrices via the tensor product can fail [33], as the resulting process matrix contains causal ‘double-loops’ [6], which give rise to the ‘grandfather paradox’, or equivalently, to unnormalised probabilities.

In this work, we show that under weak assumptions (bilinearity, every output is a valid process matrix, reduction to the usual tensor product for definite causal structure) there exists no composition that allows the experimenters to have access to multiple shared processes. This result means that many information theoretic protocols relying on many copies of a resource have no straightforward generalization to process matrices.

2. Preliminary notions

The most general operation that can be performed on a quantum system is represented by a quantum instrument, namely, a collection \{\mathcal{M}_{a|x}\} of completely positive trace-nonincreasing maps that sum up to a trace-preserving map \(M = \sum_a M_a\). An operation represented by the instrument \{\mathcal{M}_a\} will give an output \(a\) with probability \(P(a) = \text{tr}[M_a(\rho)]\) and transformation of the state \(\rho \mapsto M_a(\rho)/P(a)\). We admit the possibility of an input \(x\), and label the corresponding operations as \{\mathcal{M}_{a|x}\}. Such maps can be represented as matrices via the Choi-Jamiolkowski isomorphism [34, 35]

\[
\mathcal{M}_{a|x} \mapsto M_{a|x} = \sum_{\bar{a}} \langle \bar{j}| \otimes M_{a|x}(i) \langle j| ^\dagger,
\]

We will call \(M_{a|x}\) the Choi matrix of \(\mathcal{M}_{a|x}\). Consider a set of local operations, i.e. Choi matrices, \(\{M_{a|x}\}_{a|x}\) and \(\{M_{b|y}\}_{b|y}\), associated with Alice’s and Bob’s laboratories, where \(A\) denotes Alice’s input–output space \(\mathcal{H}_A \otimes \mathcal{H}_{A^d}\), and similarly for \(B\). A process \(W\) is understood as the most general linear mapping of such operations into probabilities, which can be represented using the trace inner product as

\[
p(ab|xy) = \text{tr}[(M^A_{a|x} \otimes M^B_{b|y}) W^\dagger],
\]

where \(\bar{T}\) denotes the transposition in the computational basis. A visual representation of this probability rule is given in figure 1. In order to obtain valid probabilities, i.e. non-negative numbers summing up to one, for arbitrary operations \(\{M^A_{a|x}\}_{a|x}, \{M^B_{b|y}\}_{b|y}\) (including operations that involve shared entangled ancillary systems), it can be proven [9] that the following constraints must be satisfied

\[
W \geq 0,
\]

\[
\text{tr}W = d_O = d_A d_{B'},
\]

\[
b_{b}b'_{B'} W = A_{b}b'b' W',
\]

\[
A_{a}a'_{B_0} W = A_{a}a'b' W',
\]

\[
W = b'b' W + A_{a}a' W - A_{a}a'b' W',
\]

Alternatively, one could define \(M_{a|x}\) with a global transposition \(t\), taken w.r.t. the \(|ij\rangle\) basis, as in [9]. This allows one to write the process matrix associated to a quantum state \(\rho\) shared between the parties simply as \(\rho_t \otimes I_{0}\), instead of \(\rho^t \otimes I_{0}\). We will not use this convention here.
where $\chi W := \frac{1}{\delta} \otimes t_{\chi} W$. The linear constraints in equations (4)–(7) can be written in a more compact form as

$$L_V(W) = W,$$

where $L_V$ is the projector onto the subspace of operators in $L(L(H_{AB}))$ that satisfy equations (5)–(7). We will denote such a linear subspace as $L_V \subseteq L(L(H_{AB}))$. This projector enforces the normalization of probabilities, and can be interpreted as preventing the paradoxes that would occur in processes with ‘causal loops’ [6]. It is also convenient to define $W \subseteq L(L(H_{AB}))$ as the set of matrices that satisfy the conditions in equations (3)–(7), and similarly $W'$ for the spaces $A'B' := \mathcal{H}_{A'} \otimes \mathcal{H}_{B'} \otimes \mathcal{H}_{R_{1}} \otimes \mathcal{H}_{R_{2}}$. If $R_{1}W = W$, one can show that Bob cannot signal to Alice, i.e. $p(a|x, y) = p(a|x, y')$ for all $a$, $x$, $y$, $y'$, we denote it as $A \preceq B$ and we say that the process is causally ordered [9]. Similarly, the case $A_{0}R_{2}W = W$ corresponds to the opposite causal order and it is denoted as $B \preceq A$. If $A_{0}R_{1}W = W$ we have at the same time $A \preceq B$ and $B \preceq A$, then $W$ represents a bipartite quantum state and we have no-signaling in both directions.

Similarly, in the case of $N$ parties $A^{1}, \ldots, A^{N}$, linear constraints can be written in the compact form [9]

$$L_{V_{i}}(W) = \begin{bmatrix} 1 - \prod_{j=1}^{n} (1 - A^{1}_{i} + A^{1}_{i} A^{2}_{i}) + \prod_{j=1}^{n} A^{2}_{i} A^{3}_{i} \end{bmatrix} W = W,$$

where the index $i$ runs through the different parties. Notice that if $W = W_{1} \otimes W_{2}$, then the set $\{1, \ldots, N\}$ can be split as $\chi_{1} \cup \chi_{2}$, with $\chi_{1} \cap \chi_{2} = \emptyset$, where $\chi_{k}$ indexes the parties appearing in $W^{k}$. Then

$$L_{V_{i}}(W_{1} \otimes W_{2}) = W_{1} \otimes W_{2} \iff \begin{bmatrix} 1 - \prod_{i \in \chi_{1}} (1 - A^{1}_{i} + A^{1}_{i} A^{2}_{i}) + \prod_{i \in \chi_{1}} A^{2}_{i} A^{3}_{i} \end{bmatrix} W_{1} = W_{1} \text{ and } \begin{bmatrix} 1 - \prod_{i \in \chi_{2}} (1 - A^{1}_{i} + A^{1}_{i} A^{2}_{i}) + \prod_{i \in \chi_{2}} A^{2}_{i} A^{3}_{i} \end{bmatrix} W_{2} = W_{2}.$$

2.1. Examples

The process matrix formalism allows one to treat quantum states, quantum channels, and even situations where the causal order is indefinite, in a unified way. For example, the process matrix associated to a quantum state $\rho$ can be described as a single party process matrix, as $W = \rho^{A_{i}} \otimes I^{B_{i}}$. The process matrix associated to $N$ spatially separated copies of the state is a $N$-partite process $W = \prod_{i=1}^{N} \rho^{A^{i} \otimes A^{i}}$, where each of the $A^{i}$ and $A^{i}_{0}$ are isomorphic. However, one could also consider the same $W$ as a global single party process, with input Hilbert space $A_{i} = \prod_{i} A^{i}_{i}$, and output Hilbert space $A_{0} = \prod_{i} A^{i}_{0}$.

A quantum channel $C: L(H_{A_{0}}) \rightarrow L(H_{B_{0}})$, connecting the output Hilbert space of Alice to Bob’s input Hilbert space, can be described in process matrix language as $W = C^{A_{0}B_{i}}$, where $C$ is the Choi matrix of the channel $C$, as defined by equation (1). The process matrix describing $N$ parallel uses of the channel $C$ is simply $W = \prod_{i=1}^{N} C^{A^{i}B^{i}}$. Again, this process can be considered as a $2N$-partite process, or as a bipartite process with $A_{0} := \prod_{i} A^{i}_{0}$ and $B_{0} := \prod_{i} B^{i}_{0}$.

3. Composition rules

From the above considerations, it seems that one could simply take the tensor product as a composition rule to obtain multipartite processes representing multiple independent copies of a resource. In fact, equation (10)
implies that whenever the linear constraints are satisfied for both \( W_1 \) and \( W_2 \), then the corresponding multipartite constraints will be satisfied for \( W_{12} \).

The situation is different, however, if we require \( W_1 \) and \( W_2 \) to be shared by the same parties. To keep the discussion simple, consider only two parties, Alice and Bob, who share two possible processes, \( W_1, W_2 \). We want now to create the composite process \( W_{12} \) such that it is still a bipartite one, i.e. Alice can access both the systems \( A \) and \( A' \), and Bob both \( B \) and \( B' \). If both processes have the same definite causal order, i.e., \( W_1 = W_{11} \) and \( W_2 = W_{12} \), then, we know from standard quantum theory that the right operation for composing such processes is \( W_{12} = W_{12} \). This composition rule is represented in figure 2. One can easily prove that whenever the two processes do not have the same definite causal order, then \( L_{W_{12}}(W_{12} \otimes W_{12}) \neq W_{12} \otimes W_{12} \), where \( L_{W_{12}} \) is taken with respect to the bipartition \((AA', BB')\) [33]. For instance, consider the process

\[
W \otimes W, \quad \text{with} \quad W = \frac{1}{2} (W^A \preceq B + W^B \preceq A)
\]

then, it is sufficient to check directly the violation of equation (7) with respect to the bipartition \((AA', BB')\), namely, \( W \otimes W = b_{B_1 B_2} (W \otimes W) + a_{A_1 A_2} (W \otimes W) - a_{A_1 A_2} b_{B_1 B_2} (W \otimes W) \). This problem is illustrated in figure 3, where two processes \( W, W' \) corresponding to channels in different directions can be seen to lead to a ‘loop’, and to unnormalised probabilities. It is then natural to ask whether the tensor product can be replaced with another composition rule.

One may, however, argue that it is in principle possible to define more general composition rules that take this problem into account. For instance, one could take the tensor product and then ‘project’ back the corresponding operator onto the space of valid processes, or one could first decompose the process into a linear combination of processes in a definite order, then take the tensor product of each term and then recombine them. There are infinitely many possible recipes to define a composition rule; an abstract prescription for general composition rules is provided in [36, 37]. In the following, we will ask three reasonable and physically motivated requirements and show that there is no way of satisfying all three.
To define our composition rule \( \mu \), we may ask the following minimal requirements:

**R.1** \( \mu(W_1, W_2) \) is a valid process w.r.t. the bipartition \( AA', BB' \), for \( W_1 \in \mathcal{W}, W_2 \in \mathcal{W}' \) (validity).

**R.2** \( \mu(W_1, W_2) = W_1 \otimes W_2 \) if \( W_1 \in \mathcal{W}, W_2 \in \mathcal{W}' \), and \( W_1, W_2 \) are in the same order, i.e. \( (A_0, W_1 = W_i \text{ and } A_o, W_2 = W_2) \), or \( (B_0, W_1 = W_i \text{ and } B_o, W_2 = W_2) \) (consistency).

**R.3** \( \mu(W_1, W_2) \) is convex linear in both arguments (convex linearity);

Requirement R.1 is needed for the composition of two processes to still belong to a bipartite scenario, i.e. where Alice has access to both systems \( AA' \), and Bob to \( BB' \). R.2 is a consistency condition, i.e. the case of definite order should coincide with standard quantum theory. R.3 can be derived by requiring that our composition is well-behaved with respect to statistical mixtures, i.e. classical randomness, as explained in appendix A.

It will be interesting to first consider a weaker assumption than R.1, because it will help us to single out the usual mathematical tensor product as a composition rule:

**R'.1** \( \mu(W_1, W_2) \geq 0 \) for \( W_1 \in \mathcal{W}, W_2 \in \mathcal{W}' \) (positivity);

Assume that \( \mu \) is a composition rule satisfying R'.1 (or R.1), R.2, R.3. Then there is a unique real-linear extension \( \mu^\ell \) that satisfies \( \mu^\ell(W_1, W_2) = \mu(W_1, W_2) \), for all \( W_1 \in \mathcal{W}, W_2 \in \mathcal{W}' \). By construction this extension satisfies:

**R'.3** \( \mu(W_1, W_2) \) is real linear in both arguments (linearity);

For the linear extension, we only demand R'.1 (or R.1) for process matrices as inputs, so it will trivially continue to be satisfied. As R.2 itself is a (bi)linear condition, the linear extension will satisfy it even when it is extended to the linear span of process matrices:

**R'.2** \( \mu(W_1, W_2) = W_1 \otimes W_2 \) if \( W_1 \in \mathcal{L}(\mathcal{H}_{AB}), W_2 \in \mathcal{L}(\mathcal{H}_{A'B'}), \) and \( W_1, W_2 \) satisfy \( (A_0, W_1 = W_1 \text{ and } A_o, W_2 = W_2) \), or \( (B_0, W_1 = W_1 \text{ and } B_o, W_2 = W_2) \) (consistency)

Details can be found in appendix A.

With our axioms, we will be able to prove

**Theorem 1.** The only function satisfying R'.1, R'.2, R'.3 is \( \mu(W_1, W_2) = W_1 \otimes W_2 \).

Theorem 1 can be applied to the linear extension \( \mu^\ell \), implying that \( \mu(W_1, W_2) = W_1 \otimes W_2 \), and from that it will follow

**Theorem 2.** There exists no function satisfying R.1–R.3.

In particular, theorem 1 will imply that for the multipartite case the choice of the composition rule is unique. We will prove theorem 1 for the simple case of local systems consisting of \( n \)-qubits, i.e. with local dimension \( 2^n \) for each one of \( A_1, A_1', \ldots, B_{0n}, B_{0n}' \), the general proof can be found in appendix B. Given theorem 1, for the proof of theorem 2 it is sufficient to use the result of [33], or the example in equation (11).

First, we need the following

**Lemma 1.** Given \( A_1, A_2 \) Hermitian operators such that \( A_1 \in \mathcal{L}(\mathcal{H}_{AB}) \) and \( A_2 \in \mathcal{L}(\mathcal{H}_{A'B'}) \), and let \( \mu \) be a composition rule satisfying R'.1–R.3. Then \( \mu(A_1, A_2) = \mu(A_1, A_2)' \) and \( \| \mu(A_1, A_2) \| \leq \| A_1 \otimes A_2 \| \).

**Proof.** For \( A \) Hermitian, its norm can be written as: \( \| A \| = \min \{ \lambda \mid -\lambda I \leq A \leq \lambda I \} \). Consider \( A_1 \in \mathcal{L}(\mathcal{H}_{AB}) \) and \( A_2 \in \mathcal{L}(\mathcal{H}_{A'B'}) \) Hermitian and with \( \lambda_i = \| A_i \| \) for \( i = 1, 2 \). We define

\[
W_i^+ = \lambda_i I \pm A_i, \quad W_i^- = \lambda_i I \pm A_i,
\]

which are valid processes, up to a normalization factor, on the spaces \( AB \) and \( A'B' \). We then have

\[
0 \leq \frac{\mu(W_1^+, W_2^+) + \mu(W_1^-, W_2^-)}{2} = \lambda_1 \lambda_2 I + \mu(A_1, A_2),
\]

\[
0 \leq \frac{\mu(W_1^+, W_2^-) + \mu(W_1^-, W_2^+)}{2} = \lambda_1 \lambda_2 I - \mu(A_1, A_2),
\]

(13)

5
which implies \( \mu(A, A_2) = \mu(A_1, A_2) \) and \( \mu(A_1, A_2) \) is defined on \( \mathcal{L} = \{ M \in \mathcal{L}(\mathcal{H} \otimes \mathcal{H}) \} \). In the above, we used R’.1 for positivity, then R’.3 to split the different terms, and finally, R’.2 to take the identity out of \( \mu \).

For the following, we need to specialize the form of the operator \( A_1 \) and \( A_2 \). We define the set of tensor products of either traceless operators or the identity as

\[
P_{TIA} := \{ M = X_{a_1}^k \otimes X_{a_2}^j \otimes X_{b_1}^k \otimes X_{b_2}^j \mid M \in \mathcal{L}(\mathcal{H}_{AB}), X^i \text{ identity or traceless} \},
\]

and analogously for \( A'B' \). For \( M \in P_{TIA} \), an operator of the form \( 1 + M \) is, up to normalization, a causally ordered process. With the above definition, we prove the following

**Lemma 2.** Let \( \mu \) be a composition rule satisfying R’1–3, and let \( M \in P_{TIA} \) and \( N \in P_{TIA} \) be Hermitian operators with eigenvalues in the interval \([-1, 1]\). Given an eigenvector \( |k\rangle \) of \( M \) with eigenvalue \((-1)^k\) and an eigenvector \( |j\rangle \) of \( N \) with eigenvalue \((-1)^j\), we have

\[
\mu(M, N)|k, j\rangle = (-1)^{k+j}|k, j\rangle
\]

**Proof.** To prove the lemma, it is sufficient to consider the (unnormalized) processes \( W^k_i := I + (-1)^{k+1}M \) and \( W^j_\ell := I + (-1)^{j+1}N \). By R’.2, \( \mu(I, I) = I \otimes I \) and \( \mu(M, I) = M \otimes I \), since for \( M \in P_{TIA} \), either \( A_0\mathcal{M} = \mathcal{M} \) or \( B_0\mathcal{M} = \mathcal{M} \). Then

\[
\mu(W^k_i, W^j_\ell) = I + (-1)^{k+1}M \otimes I + (-1)^{j+1}I \otimes N + (-1)^{j+k}M \otimes N,
\]

by R’.2 and R’.3, and finally, by R’.1

\[
0 \leqslant \langle k, j | \mu(W^k_i, W^j_\ell)|k, j\rangle = 1 - 1 - 1 + (-1)^{j+k} \langle k, j | \mu(M, N)|k, j\rangle,
\]

which implies \( \mu(M, N)|k, j\rangle = (-1)^{j+k}|k, j\rangle \), since \( \|\mu(M, N)\| \leqslant 1 \), by lemma 1.

A straightforward corollary of lemma 2 is that \( \mu(M, N) = M \otimes N \) whenever \( M, N \) have eigenvalues only in \{-1, 1\}. By linearity, this is enough to prove theorem 1 for all processes defined on \( n \)-qubit systems (i.e. local dimension \( 2^n \)) since we have a basis of operators, given by tensor products of Pauli matrices and the identity, that satisfy the assumptions. The same reasoning can be extended to arbitrary dimensions, see the details in appendix B.

### 4. Discussion and conclusions

In this letter, we considered the parallel composition of process matrices. As the tensor product is known to lead to invalid process matrices, we investigated whether there is another map that can describe this parallel composition. As the tensor product is known to lead to invalid process matrices, we investigated whether there is another map that can describe this parallel composition. We only asked for three weak desiderata: First of all, in contrast to the usual tensor product, it should always result in a valid process matrix. Furthermore, it should reduce to the familiar tensor product in the case of de finite causal order. At last, we demanded bilinearity for compatibility with the interpretation of convex mixtures as statistical mixtures. However we have seen that even those reasonable desiderata are incompatible with each other.

Our results imply that an information theory of general quantum processes cannot rely on the assumption that multiple independent processes can be shared between two (or more) parties. In information theory, it is typical to assume that many independent samples of a random source, many independent uses of a channel, etc. are available, and that agents can perform global operations on many independent copies of the resource; this will not be possible in an information theory of general quantum processes. Rather, these results suggest that the proper setting for defining information-theoretic quantities such as entropies, capacities, etc., for process matrices is single-shot information theory [38–40].

One can infer from the main proof that even the case of two channels with opposing signaling direction will lead to a contradiction, which is unsurprising in the usual case of quantum mechanics on a fixed background spacetime. Indeed, suppose that an event A is in the causal past of an event B, and that A‘ is in the causal future of B’. Our desiderata that A and A’ correspond to the same party can be interpreted as requiring that the events A, A’ occur at the same space-time point p. This could be the case, but then B must be in the future light-cone of p, while B’ must be in it’s past light-cone. It is thus impossible to satisfy the requirement that B and B’ also occur at the same space-time point.

Therefore any composition rule for process matrices must take care of removing the two-way signaling terms, whose impossibility has a clear interpretation as discussed above. We have shown that there is no linear way of doing so, if we ask for that our composition rule reduces to the usual tensor product in the case of two processes with the same definite causal order.
However, there might exist reasonable nonlinear composition rules, in the cases where processes have a concrete physical interpretation. A meaningful way to define an event for the composite party \( AA' \) is by the ‘simultaneous’ entering of both systems \( \mathcal{H}_A \) and \( \mathcal{H}_A' \) in a localized laboratory, and similarly for \( BB' \). There can be a probability that the systems do not enter the laboratories simultaneously, in which case it is necessary to post-select on the runs of the experiment where this was indeed the case. Since the post-selection probability depends on the two processes that we wish to compose, the map will be nonlinear. An important issue with such a post-selected composition map for information-theoretic applications is that the parallel composition of resources is usually a ‘free operation’, while in the post-selected case it would have a probability of failure.

Appendix A. Linearity and convex linearity

In this appendix, we discuss convex-linearity and the linear extension of convex maps. First, let us argue why convex-linearity is a reasonable physical assumption. In operational approaches to physical theories [41, 42], one studies the probabilities that can be obtained from an abstract set of preparations and measurements. Given two preparations \( \alpha \) and \( \beta \), there exists another preparation \( \gamma \) that consists of preparing \( \alpha \) with classical probability \( p \) and preparing \( \beta \) with probability \( 1 - p \). The probability for any measurement on \( \gamma \) is the weighted sum of the probabilities associated with preparations \( \alpha \) and \( \beta \). If we associate ‘states’ with preparations, this means that the state space is convex linear. For example, the density matrix formalism can be seen to arise by adding classical uncertainty to the pure state formalism (i.e. kets in a Hilbert space). If one knows that with probability \( p_1 \), one prepares \( |j\rangle \), then the density matrix is given by \( \rho = \sum_j p_j |j\rangle \langle j| \). Another motivation for allowing arbitrary probabilistic mixtures appears in [43, 44], where it is shown that it implies that optimal compression is equivalent to linear compression.

The same interpretation can be used for process matrices: if the process matrices \( W_1 \) are prepared with probabilities \( p_1 \), then all expectations values (and by that all statistics) can be calculated with the effective process matrix \( W = \sum_j p_j W_j \). This can be seen by noting that \( \rho(a, b) = \text{Tr}[W M_1(a) \otimes M_2(b)] \) is a linear function in \( W \) and applying the law of total probability.

Consistency demands that the composition rule \( \mu \) remains compatible with this interpretation of convex mixtures: if the first process is \( W_1 \) with probability \( p_1 \) and the second process is \( W_2 \) with probability \( p_2 \), then the effective process matrices determining the statistics are \( W = \sum_j p_j W_j \) and \( W' = \sum_{jk} p_{jk} W_{jk} \). The resulting combined process would be \( \mu(\sum_j p_j W_j, \sum_{jk} p_{jk} W_{jk}) \). However, a different point of view would be to say: with probabilities \( p_j \) and \( p_{jk} \), we combined the processes \( W_j \) with \( W_{jk} \) to \( \mu(W_j, W_{jk}) \). So we prepared \( \mu(W_j, W_{jk}) \) with probability \( p_j p_{jk} \). Now, the effective process matrix is described by \( \sum_{jk} p_{jk} \mu(W_j, W_{jk}) \). As both points of view describe the same operational scenario, they have to be consistent:

\[
\mu \left( \sum_j p_j W_j, \sum_{jk} p_{jk} W_{jk} \right) = \sum_{jk} p_{jk} \mu(W_j, W_{jk}).
\]

Next, we explain in further detail how to extend a function satisfying R.1 (or R’1), R.2 and R.3 to a function satisfying R.1 (or R’1), R.2 and R.3 on the linear span of all the process matrices.

Constructing the (bil)linear extension itself is a standard procedure in quantum information theory and is explained e.g. in [41, 42] for general abstract state spaces. Let \( S_1, S_2 \) be two convex sets, and let \( f : S_1 \rightarrow S_2 \) be a convex linear map. Let \( V_1, V_2 \) be the real vector spaces obtained respectively from \( S_1, S_2 \) by taking their linear span. Then \( f \) can be extended in the obvious way to a linear function \( f^\mathbb{L} : V_1 \rightarrow V_2 \), defined by \( f^\mathbb{L}(\lambda a + b) = \lambda f(a) + f(b) \), for all \( a, b \in S_1, \lambda \in \mathbb{R} \).

However, we still need to check that the bilinear extension still satisfies our postulates: we do not change R.1 (or R’1), i.e. we only demand the output to be a process matrix (or positive) if the inputs are process matrices.
Therefore R.1 (or R’.1) trivially continues to hold as the extension does not change the function on inputs that are process matrices.

Less trivial is how to generalize R.2. We will explicitly show that it still holds for the cases we need. Let us assume we have operators $M_1 \in L_V(L(H_{1AB}))$ and $M_2 \in L_V(L(H_{1'2}))$ with $\lambda_1 M_1 = M_1$ and $\lambda_2 M_2 = M_2$ (or alternatively $\lambda_1^0 M_1 = M_1$ and $\lambda_2^0 M_2 = M_2$). We now show that

$$
\mu^k(M_1, M_2) = M_1 \otimes M_2. \tag{A2}
$$

By definition, $M_1$ and $M_2$ are allowed terms satisfying the projective condition (8). Therefore there exist $\lambda_1, \lambda_2$ such that $\frac{1}{\lambda_1} + \lambda_1 M_1$ and $\frac{1}{\lambda_2} + \lambda_2 M_2$ are valid process matrices. Similarly $\frac{1}{\lambda_1^0}$ itself is a valid process matrix, with no signaling at all. Using R.2 for the original $\mu$ on valid process matrices, we find for the linear extension:

$$
\mu^k\left(\frac{1}{d_\ell} + \lambda_1 M_1, \frac{1}{d_{\ell'}} + \lambda_2 M_2\right) = \mu\left(\frac{1}{d_\ell} + \lambda_1 M_1, \frac{1}{d_{\ell'}} + \lambda_2 M_2\right) = \left(\frac{1}{d_\ell} + \lambda_1 M_1\right) \otimes \left(\frac{1}{d_{\ell'}} + \lambda_2 M_2\right) \otimes 1 + \lambda_1 M_1 \otimes 1.
$$

Therefore by bilinearity we find $\mu^k(M_1, 1) = M_1 \otimes 1$ and similarly $\mu^k(1, M_2) = 1 \otimes M_2$. Similarly, applying R.2 to the process matrices $\frac{1}{d_\ell} + \lambda_1 M_1$ and $\frac{1}{d_{\ell'}} + \lambda_2 M_2$, which have the same signaling direction, we obtain

$$
\mu^k\left(\frac{1}{d_\ell} + \lambda_1 M_1, \frac{1}{d_{\ell'}} + \lambda_2 M_2\right) = \mu\left(\frac{1}{d_\ell} + \lambda_1 M_1, \frac{1}{d_{\ell'}} + \lambda_2 M_2\right) = \left(\frac{1}{d_\ell} + \lambda_1 M_1\right) \otimes \left(\frac{1}{d_{\ell'}} + \lambda_2 M_2\right). \tag{A3}
$$

Collecting our results and using bilinearity on the left hand side of equation (A3) above, we finally see that R’.2 is satisfied:

$$
\mu^k(M_1, M_2) = M_1 \otimes M_2. \tag{A4}
$$

## Appendix B. Proof of theorem 1 in arbitrary dimension

In this appendix, we will extend the proof of theorem 1 to the case of arbitrary dimension. We start with the following

**Lemma 3.** Let $M \in \text{PTI}_{1A}$ and $N \in \text{PTI}_{1'2'}$ be Hermitian operators such that $|k\rangle = |k\rangle_{A_0} \otimes |k\rangle_{B_0} \otimes |k\rangle_{B_1} \otimes |k\rangle_{B_2}$ is an eigenvector for $M$, with eigenvalues given, according to the above factorization, by the products $\lambda_k = \lambda_k^{(1)} \lambda_k^{(2)} \lambda_k^{(3)} \lambda_k^{(4)}$, with $\lambda_k^{(i)} \in \{-1, 0, 1\}, i = 1, 2, 3, 4$, and, similarly, $|j\rangle = |j\rangle_{A_1'} \otimes |j\rangle_{B_1'} \otimes |j\rangle_{B_2'} \otimes |j\rangle_{B_2''}$ is an eigenvector of $N$, with eigenvalue $\eta_j = \eta_j^{(1)} \eta_j^{(2)} \eta_j^{(3)} \eta_j^{(4)}$, with $\eta_j^{(i)} \in \{-1, 0, 1\}, i = 1, 2, 3, 4$. We then have

$$
\mu(M, N)|k\rangle|j\rangle = \lambda_k \eta_j |k\rangle|j\rangle. \tag{B1}
$$

**Proof.** The cases $\lambda_k, \eta_j = \pm 1$ are included in lemma 2. Let us consider the case $M|k\rangle = 0$ and $N|j\rangle = 0$, the case $M|k\rangle = N|j\rangle = 0$ can be obtained in a similar way, by applying the same argument first to $M$, then to $N$. Since $M$ is in PTI_{1A}, we can write it as $M = X_{k_0}^{(1)} \otimes X_{k_1}^{(2)} \otimes X_{k_2}^{(3)} \otimes X_{k_3}^{(4)}$. Let us now further assume $X_{k_1}|k\rangle_{A_0} = 0$, and $X_{k'}|k\rangle_{Y_0} = 0$ for $i = 2, 3, 4, Y = A_0, B_1, B_2, B_3$, in particular, this implies that $|k\rangle$ are eigenvectors for eigenvalues $\pm 1$ for $i = 2, 3, 4$. We can then write:

$$
X = (X^1 + |k\rangle|k\rangle - (k + 1)|k\rangle(1 + 1)|k\rangle + [(k + 1)|k\rangle(1 + 1)|k\rangle - |k\rangle|k\rangle] = X^1 + X^{u1}, \tag{B2}
$$

where $(k + 1)|k\rangle$ is a vector orthogonal to $|k\rangle$. Then $X^1, X^{u1}$ are both traceless and $X^{u1}|k\rangle = |k\rangle$, $X^{u1} = -|k\rangle$. We then have that $M' = X_{k_0}^{(1)} \otimes X_{k_1}^{(2)} \otimes X_{k_2}^{(3)} \otimes X_{k_3}^{(4)}$ and $M'' = X_{k_0}^{(1)} \otimes X_{k_1}^{(2)} \otimes X_{k_2}^{(3)} \otimes X_{k_3}^{(4)}$ are again in PTI_{1A}. Thus, by lemma 2

$$
\mu(M, N)|k\rangle|j\rangle = \mu(M', M'', N)|k\rangle|j\rangle = \mu(M', N)|k\rangle|j\rangle + \mu(M'', N)|k\rangle|j\rangle = M' \otimes N|k\rangle|j\rangle + M'' \otimes N|k\rangle|j\rangle = 0. \tag{B3}
$$

If another operator, say $X^2$, is zero on the corresponding eigenvector, say $|k\rangle_{A_0}$, we can again repeat the construction in equation (B2) to construct $X'^2, X''^2$ with $+1, -1$ eigenvalues and use again linearity and lemma 2. Similarly, the same argument can be extended to all $X^i$ and to $N$. \hfill \square

To conclude the proof of theorem 1, it is sufficient to construct a basis of operators containing the identity and where each element, except the identity, is traceless and with eigenvalues in $\{-1, 0, 1\}$. Let $\mathcal{H}$ be a Hilbert space with dimension $d$, and let $\{|k\rangle\}_{k=1}^d$ be a basis for $\mathcal{H}$. The space of Hermitian operators on $\mathcal{H}$ is a real vector space of dimension $d^2$. We define the following operators

\[ \mu^k(M_1, M_2) = M_1 \otimes M_2, \]
\[ Z_i = |i\rangle \langle i| - |i + 1\rangle \langle i + 1|, \quad 1 \leq i \leq d - 1, \]  
(B4)  
\[ X_{jk} = |j\rangle \langle k| + |k\rangle \langle j|, \quad 1 \leq j < k \leq d, \]  
(B5)  
\[ Y_{jk} = i(|j\rangle \langle k| - |k\rangle \langle j|), \quad 1 \leq j < k \leq d, \]  
(B6)

which are traceless, hermitian and with eigenvalues in \{-1, 0, 1\}. The \(X_{jk}\) and \(Y_{jk}\) are also known as part of an operator basis called \textit{Generalized Gell-Mann matrices}\cite{45}. For completeness we now show that, together with \(\mathbb{I}\), the above set of matrices form a basis for the space of Hermitian operators on \(\mathcal{H}\). It is clear that the \{\(X_{jk}\)\} and \{\(Y_{jk}\)\} span the space of Hermitian operators whose diagonal is zero in the \(|k\rangle\) basis. All that remains to be shown is that \{\(\mathbb{I}, Z_i\)\} forms a basis for the space of diagonal real matrices, which we prove by expressing the basis \{|\(k\rangle\langle k|\}\} in terms of the new basis \{\(\mathbb{I}, Z_i\)\}. Notice that for \(1 \leq i \leq d - 1\)

\[
\sum_{j=i}^{d-1} Z_j = |i\rangle \langle i| - |d\rangle \langle d|, 
\]  
(B7)  

and also that

\[
\sum_{j=1}^{d-1} jZ_j = \sum_{j=1}^{d-1} |j\rangle \langle j| - (d - 1)|d\rangle \langle d| = \mathbb{I} - d|d\rangle \langle d|. 
\]  
(B8)

Combining the above two expressions gives

\[
|d\rangle \langle d| = \frac{1}{d} \mathbb{I} - \frac{1}{d} \sum_{j=1}^{d-1} jZ_j, 
\]  
(B9)  
\[
|i\rangle \langle i| = \frac{1}{d} \mathbb{I} + \frac{1}{d} \sum_{j=i}^{d-1} Z_j - \frac{1}{d} \sum_{j=i}^{d-1} jZ_j, \quad 1 \leq i \leq d, 
\]  
(B10)

which concludes that \{\(\mathbb{I}, Z_i, X_{jk}, Y_{jk}\)\} is a basis for the space of Hermitian operators of \(\mathcal{H}\).

We can use the above construction to build a basis for \(\mathcal{L}(\mathcal{H}_{A1} \otimes \mathcal{H}_{A2} \otimes \mathcal{H}_{B1} \otimes \mathcal{H}_{B2})\) consisting of tensor products of local Hermitian operators whose eigenvalues are in \{-1, 0, 1\}. We then remove from this basis all the terms that do not satisfy the linear constraints \(L_{\mathcal{N}}\). This gives us a basis for the linear space of valid \(W\)s, which is contained in \(\mathcal{PTI}_{AB}\). We will call this basis simply \{\(M_{ij}\)\}_{ij \in \mathcal{E}}, and by lemma 3, we have

\[
\mu(M_{ij}, M_{ij}) = M_{ij} \otimes M_{ij}, \quad (B11) 
\]

We can then decompose any pair \(W, W'\) as

\[
W = \mathbb{I} + \sum_i c_i M_{ii}, \quad W' = \mathbb{I} + \sum_i d_i M_{ii}, \quad (B12)
\]

and apply \(\mu\), namely

\[
\mu(W, W') = \mathbb{I} + \sum_i c_i M_{ii} \otimes \mathbb{I} + \mathbb{I} \otimes \sum_i d_i M_{ii} + \sum_{ij} c_i d_j \mu(M_{ij}, M_{ij}) = \mathbb{I} + \sum_i c_i M_{ii} \otimes \mathbb{I} + \mathbb{I} \otimes \sum_i d_i M_{ii} + \sum_{ij} c_i d_j M_{ij} \otimes M_{ij} = W \otimes W', \quad (B13)
\]

which concludes the proof of theorem 1.
